Two dogs and two cats served as subjects. The dogs received sodium amytal and nembutal intravenously, avertin per rectum, alcohol and paraldehyde by stomach tube, and morphia, hyoscine and bulbocapnine subcutaneously. The gaseous anæsthetics were administered to the cats under a bell jar. We naturally waited for full recovery from one drug before we administered a new drug or even a different dose of the same drug.

The general procedure for establishing conditioned reflexes is by now well known. The measured and recorded response may be salivary secretion or any other easily observed reaction (*cf.* Liddell, 1934).

In our work a lid-lifting response was used. This particular training procedure was described by Dworkin[2] (1935). The stimuli selected comprised auditory, visual and tactile signals. The successive tests were made at intervals of 2 to 6 minutes. During these intervals the animals had been trained not to touch the lid of the food container. Consistent absence of response between stimuli, eventually developed by training, may be called "interval inhibition" (Fig. 1A). The animals were also trained to make two discriminations, (1) between two different buzzers—"coarse" discrimination, (2) between a loud and a quiet musical tone of fixed frequency —"fine" discrimination. The time of incidence of the signals, as well as that of the animals' response, was recorded graphically. Thus we had information as to the latent period, presence or absence of conditioned response, duration of conditioned and unconditioned phases, and finally the amount of interval inhibition.

The latent period of the positive responses varied between 1 and 3 seconds. Often it was just as short for a visual as for a tactile or auditory stimulus. Nevertheless, a loud sound usually evoked a response sooner than a quiet sound; similarly, the latent period for a strong light was often shorter than for a weak light. When a negative stimulus was turned on for differentiation there was at times a slight turning of the head away from the food container, and other signs of general irritation, but no attempt to raise the lid (see Fig. 1B).

RESULTS

Our observations indicate that the eleven drugs tested may be classed into three main

SHORT REPORTS

Rotavirus neutralisation by human milk

There has been considerable publicity recently about the benefits of breast-feeding in giving protection from infection. We have investigated the effect of mother's serum and breast milk, taken daily for five days after birth, on rotavirus infection of cells in vitro.

Materials, methods, and results

Milk and blood samples were taken by staff at Birmingham Maternity Hospital and at Marston Green Maternity Hospital, Birmingham. Milks were clarified by centrifugation, and milks and sera were heated at 56 C for 30 minutes to inactivate complement.

Human rotavirus was obtained from the faeces of children with acute diarrhoea admitted to East Birmingham Hospital. The neutralisation test was carried out as previously described.[1 2] Human rotavirus infects but fails to replicate in LLC MK_2 cells and the infected cells can be detected by an indirect immunofluorescent technique. The neutralisation titre of a milk or serum was the dilution that gave a 50% or greater reduction of fluorescent foci compared with the control. The specific rotavirus fluorescent antibody titres of sera and milks were determined by their reaction with rabbit rotavirus infected LLC MK_2 cells[2] in an indirect immunofluorescent test.

The rotavirus neutralising titres of the randomly picked mothers' sera varied from 1/10 to 1/640 (see table). Most of the first milk samples had a neutralising titre close to that of the mother's serum, but this fell rapidly in the puerperium so that, by the fifth day, only the two mothers with the highest serum neutralising titres had milk titres of 1/5 or greater.

All the sera and milks were tested by indirect immunofluorescence for specific reaction with rotavirus infected cells. Specific fluorescence was given by all the sera and the early milks, but the titres were always less than the rotavirus neutralising titres (see table). Four- and five-day milk samples gave no reaction, but it was not possible to test them undiluted because of non-specific fluorescence.

The milk samples that did not neutralise human rotavirus at 1/5 dilution were tested undiluted; the virus was completely inactivated. The same result was obtained with these milks and lamb rotavirus. A high-speed aqueous supernatant of undiluted pasteurised cows' milk and an antibody-free glycoprotein prepared from cows' milk inactivated human rotavirus completely.

Comment

We have shown by neutralisation and immunofluorescent tests that human milk in the early puerperium contains rotavirus antibodies that decline to undetectable levels by five days after birth.

Fifth-day undiluted milks inactivated human rotavirus, but it was not possible to tell whether this was due to specific antibody. As they also inactivated lamb rotavirus, however, and human rotavirus was inactivated by cows' milk and its phenol-extracted glycoprotein, we suggest it may be due to a non-specific antiviral milk factor.[3 4]

Rotavirus infection in the first few days of life is frequent and largely asymptomatic, even in breast-fed babies,[5] at the time when there is a large amount of specific rotavirus antibody in the milk. The fact that undiluted human or cows' milk also inactivates human rotavirus, however, may be an important consideration in the current baby feeding discussions.

I thank Dr D A J Tyrrell and Dr K G Nicholson of the Division of Communicable Diseases, the Clinical Research Centre, Northwick Park Hospital, Harrow, for supplying antiviral glycoprotein from cows' milk.

Response of metastatic breast cancer to combination chemotherapy according to site

Despite the clear efficacy of combination chemotherapy in producing tumour regression in some patients with metastatic breast cancer, its precise role in the overall management of this condition remains controversial. Our experience with two chemotherapy regimens leads us to believe that the major site of symptomatic disease should be the most important factor determining the choice of systemic therapy. We briefly present the evidence for this view below.

Patients, methods, and results

The two regimens were as follows: (1) vincristine 1·5—2·0 mg and doxorubicin (Adriamycin) 40–100 mg intravenously on days 1 and 8; prednisolone 20 mg by mouth daily on days 1 to 14 of a 28-day cycle (VDP); or (2) methotrexate 30–50 mg, 5-fluorouracil 500–1000 mg intravenously on days 1 and 8 with cyclophosphamide 100 mg and prednis-

Human milk mucin inhibits rotavirus replication and prevents experimental gastroenteritis.

Yolken RH[1], Peterson JA, Vonderfecht SL, Fouts ET, Midthun K, Newburg DS.

Author information

Abstract

Acute gastrointestinal infections due to rotaviruses and other enteric pathogens are major causes of morbidity and mortality in infants and young children throughout the world. Breast-feeding can reduce the rate of serious gastroenteritis in infants; however, the degrees of protection offered against rotavirus infection vary in different populations. The mechanisms associated with milk-mediated protection against viral gastroenteritis have not been fully elucidated. We have isolated a macromolecular component of human milk that inhibits the replication of rotaviruses in tissue culture and prevents the development of gastroenteritis in an animal model system. Purification of the component indicates that the antiviral activity is associated with an acidic fraction (pI = 4.0-4.6), which is free of detectable immunoglobulins. Furthermore, high levels of antiviral activity are associated with an affinity-purified complex of human milk mucin. Deglycosylation of the mucin complex results in the loss of antiviral activity. Further purification indicated that rotavirus specifically binds to the milk mucin complex as well as to the 46-kD glycoprotein component of the complex. Binding to the 46-kD component was substantially reduced after chemical hydrolysis of sialic acid. We have documented that human milk mucin can bind to rotavirus and inhibit viral replication in vitro and in vivo. Variations in milk mucin glycoproteins may be associated with different levels of protection against infection with gastrointestinal pathogens.

Author information

Abstract

Streptococcus pneumoniae is the relevant cause of bacterial meningitis, with a high-mortality rate and long-term neurological sequelae, affecting up to 50% of survivors. Pneumococcal compounds are pro-inflammatory mediators that induce an innate immune response and tryptophan degradation through the kynurenine pathway. Vitamin B6 acts as a cofactor at the active sites of enzymes that catalyze a great number of reactions involved in the metabolism of tryptophan, preventing the accumulation of neurotoxic intermediates. In the present study, we evaluated the effects of vitamin B6 on memory and on brain-derived neurotrophic factor (BDNF) expression in the brain of adult Wistar rats subjected to pneumococcal meningitis. The animals received either 10 µL of artificial cerebral spinal fluid (CSF) or an equivalent volume of S. pneumoniae suspension. The animals were divided into four groups: control, control treated with vitamin B6, meningitis, and meningitis treated with vitamin B6. Ten days after induction, the animals were subjected to behavioral tests: open-field task and step-down inhibitory avoidance task. In the open-field task, there was a significant reduction in both crossing and rearing in the control group, control/B6 group, and meningitis/B6 group compared with the training session, demonstrating habituation memory. However, the meningitis group showed no difference in motor and exploratory activity between training and test sessions, demonstrating memory impairment. In the step-down inhibitory avoidance task, there was a difference between training and test sessions in the control group, control/B6 group, and meningitis/B6 group, demonstrating aversive memory. In the meningitis group, there was no difference between training and test sessions, demonstrating impairment of aversive memory. In the hippocampus, BDNF expression decreased in the meningitis group when compared to the control group; however, adjuvant treatment with vitamin B6 increased BDNF expression in the meningitis group. Thus, vitamin B6 attenuated the memory impairment in animals subjected to pneumococcal meningitis.

Vitamin C for preventing and treating pneumonia.

Hemilä H[1], Louhiala P.

Author information

Abstract

BACKGROUND: Pneumonia is one of the most common serious infections, causing two million deaths annually among young children in low-income countries. In high-income countries pneumonia is most significantly a problem of the elderly.

OBJECTIVES: To assess the prophylactic and therapeutic effects of vitamin C on pneumonia.

SEARCH METHODS: We searched CENTRAL 2013, Issue 3, MEDLINE (1950 to March week 4, 2013), EMBASE (1974 to April 2013) and Web of Science (1955 to April 2013).

SELECTION CRITERIA: To assess the therapeutic effects of vitamin C, we selected placebo-controlled trials. To assess prophylactic effects, we selected controlled trials with or without a placebo.

DATA COLLECTION AND ANALYSIS: Two review authors independently read the trial reports and extracted data.

MAIN RESULTS: We identified three prophylactic trials which recorded 37 cases of community-acquired pneumonia in 2335 people. Only one was satisfactorily randomised, double-blind and placebo-controlled. Two trials examined military recruits and the third studied boys from "lower wage-earning classes" attending a boarding school in the UK during World War II. Each of these three trials found a statistically significant (80% or greater) reduction in pneumonia incidence in the vitamin C group. We identified two therapeutic trials involving 197 community-acquired pneumonia patients. Only one was satisfactorily randomised, double-blind and placebo-controlled. That trial studied elderly patients in the UK and found lower mortality and reduced severity in the vitamin C group; however, the benefit was restricted to the most ill patients. The other therapeutic trial studied adults with a wide age range in the former Soviet Union and found a dose-dependent reduction in the duration of pneumonia with two vitamin C doses. We identified one prophylactic trial recording 13 cases of hospital-acquired pneumonia in 37 severely burned patients; one-day administration of vitamin C had no effect on pneumonia incidence. The identified studies are clinically heterogeneous which limits their comparability. The included studies did not find adverse effects of vitamin C.

AUTHORS' CONCLUSIONS: The prophylactic use of vitamin C to prevent pneumonia should be further investigated in populations who have a high incidence of pneumonia, especially if dietary vitamin C intake is low. Similarly, the therapeutic effects of vitamin C should be studied, especially in patients with low plasma vitamin C levels. The current evidence is too weak to advocate prophylactic use of vitamin C to prevent pneumonia in the general population. Nevertheless, therapeutic vitamin C supplementation may be reasonable for pneumonia patients who have low vitamin C plasma levels because its cost and risks are low.

A RANDOMIZED, CONTROLLED TRIAL OF VITAMIN A IN CHILDREN WITH SEVERE MEASLES

GREGORY D. HUSSEY, M.B., M.SC.(LOND.), AND MAX KLEIN, M.B., F.C.P.(S.A.)

Abstract *Background.* Measles kills about 2 million children annually, and there is no specific therapy for the disease. It has been suggested that vitamin A may be of benefit in the treatment of measles.

Methods. We conducted a randomized, double-blind trial involving 189 children who were hospitalized at a regional center in South Africa because of measles complicated by pneumonia, diarrhea, or croup. The children (median age, 10 months) were assigned to receive either vitamin A (total dose, 400,000 IU of retinyl palmitate, given orally; n = 92) or placebo (n = 97), beginning within five days of the onset of the rash. At base line, the characteristics of the two groups were similar.

Results. Although clinically apparent vitamin A deficiency is rare in this population, the children's serum retinol levels were markedly depressed (mean [±SEM], 0.405±0.021 μmol per liter [11.6±0.6 μg per deciliter]), and 92 percent of them had hyporetinemia (serum retinol level <0.7 μmol per liter [20 μg per deciliter]). Serum concentrations of retinol-binding protein (mean, 30.1±2.0 mg per liter) and albumin (mean, 33.4±0.5 g per liter) were also low. As compared with the placebo group, the children who received vitamin A recovered more rapidly from pneumonia (mean, 6.3 vs. 12.4 days, respectively; P<0.001) and diarrhea (mean, 5.6 vs. 8.5 days; P<0.001), had less croup (13 vs. 27 cases; P = 0.03), and spent fewer days in the hospital (mean, 10.6 vs. 14.8 days; P = 0.01). Of the 12 children who died, 10 were among those given placebo (P = 0.05). For the group treated with vitamin A, the risk of death or a major complication during the hospital stay was half that of the control group (relative risk, 0.51; 95 percent confidence interval, 0.35 to 0.74).

Conclusions. Treatment with vitamin A reduces morbidity and mortality in measles, and all children with severe measles should be given vitamin A supplements, whether or not they are thought to have a nutritional deficiency. (N Engl J Med 1990; 323:160-4.)

MEASLES remains a devastating disease, for which specific therapy is lacking. Hopes for its control and eventual eradication rest on immunization, but measles kills about 2 million children each year[1] and cripples an untold number through blindness[2] and lung disease.[3,4] The idea that vitamin A may have a protective effect in measles was first suggested more than 50 years ago[5] but was ignored until Barclay et al.,[6] in a randomized clinical trial, found twice as many deaths in the control group (12 of 92) as among children given high doses of vitamin A (6 of 88).[6] Although the overall results did not reach statistical significance, vitamin A was significantly protective in the group under two years of age.[6]

That vitamin A should be of benefit in measles is biologically plausible.[7] Measles depresses serum levels of vitamin A,[8-11] and hyporetinemia (a serum retinol level below 0.7 μmol per liter [20 μg per deciliter]) is associated with increased mortality from the disease, particularly in children under two years of age.[11] In almost every known infectious disease, vitamin A deficiency is known to result in greater frequency, severity, or mortality.[12] Increased susceptibility to infection was one of the first features of nutritional vitamin A deficiency to be recognized,[13] and even mild deficiency appears to be associated with an increased risk of pneumonia, diarrhea, and death in childhood.[14-17] According to Scrimshaw et al., "no nutritional deficiency in the animal kingdom is more consistently synergistic with infection than that of vitamin A."[12] They list nearly 50 studies (including 8 in humans) of diseases of bacterial, viral, or protozoan origin in which vitamin A deficiency resulted in increased frequency, severity, or mortality.[12] In fact, vitamin A is sometimes referred to as the "anti-infective" vitamin.[18]

We embarked on this study because measles is a pressing problem in our part of the world[19] and because the results of Barclay et al.[6] and the circumstantial evidence appeared promising. Subsequently, acting on the same evidence, the World Health Organization recommended routine vitamin A supplementation for all children with measles in regions where vitamin A deficiency was a recognized problem and suggested that elsewhere "in countries where the fatality rate of measles is 1% or higher it would be sensible to provide vitamin A supplements to all children diagnosed with measles."[20] One difficulty with this advice is that in the communities in which measles poses the greatest problem, the mortality rate is often unknown. Another is that the recommendation is based on the less than conclusive evidence from the only two studies to have addressed the question of vitamin A therapy in measles.[5,6] These are some of the reasons why vitamin A supplementation is still not given routinely to children who are seriously ill with measles in South Africa, and presumably elsewhere.

METHODS

Children with acute measles who required hospital admission for the treatment of associated complications were entered in a randomized, double-blind, placebo-controlled trial to assess the effect of oral vitamin A on morbidity and mortality. The study was limited by a priori considerations to a fixed termination date, with a maximal enrollment of 200 cases. It was conducted from March to July 1987 at the City Hospital for Infectious Diseases, a regional center serving a population of about 2 million in Cape Town and

From the Department of Paediatrics and Child Health, University of Cape Town, Cape Town, South Africa. Address reprint requests to Dr. Klein at the Red Cross War Memorial Children's Hospital, Rondebosch 7700, South Africa.

surrounding areas. The Medical Faculty's ethics and research committee approved the study protocol.

Patient Selection and Randomization

All children under 13 years of age who were referred to the hospital for admission with measles were eligible for entry into the trial. The criteria for exclusion were vitamin A therapy before admission, xerophthalmia on admission or thereafter, rash for more than four days, or lack of parental consent.

Patients in the trial were randomly assigned to receive either 400,000 IU (120 mg) of water-miscible vitamin A (retinyl palmitate; Arovit drops, Roche, Basel, Switzerland) or an identical-appearing placebo from syringes coded according to a random-number table. The senior ward nurse gave half the dose on admission and the remainder a day later, either by mouth or by nasogastric tube. The children were cared for by the regular ward staff. Concurrent therapy included oxygen, intravenous fluids, and antibiotics as appropriate, but no additional vitamin supplements. One of the study investigators assessed the patients each day. The treatment-assignment codes were broken only at the completion of the trial.

Initial Investigations

The children's weight and height were recorded, and a venous-blood sample was drawn on entry into the trial. The weights and heights were evaluated against the standards of the National Center for Health Statistics.[21] Hemoglobin levels, white-cell counts (by Coulter model S5, Coulter Electronics, Hialeah, Fla.), and differential counts were estimated, and serum was stored at −70°C. Serum levels of total protein and albumin were measured by automated analysis (Astra-8, Beckman Instruments, Brea, Calif.). Serum concentrations of vitamin A (as retinol) were measured by high-performance liquid chromatography (Dupont Instruments, Wilmington, Del.), with concentrations of vitamin E (as alpha-tocopherol) obtained incidentally.[22] A programmable integrator was used to quantify the chromatographic results (Spectra-Physics, San Jose, Calif.). Retinol-binding protein was measured by radial immunodiffusion with a commercial kit (LC-Partigen, Behringwerke, Marburg, Federal Republic of Germany). Chest radiography and other investigations were performed when indicated.

Table 1. Base-Line Clinical Findings in 189 Children with Measles, According to Treatment Group.*

Characteristic	No. of Patients	Placebo (N = 97)	Vitamin A (N = 92)

†Expressed as a percentage of the 50th percentile of the standards of the National Center for Health Statistics.

‡$P<0.05$ for the comparison between groups.

§No patients with measles croup required airway interventions.

Assessment of Outcomes

Outcomes were assessed solely on the basis of clinical criteria. The outcome variables used were death and the severity of illness, as indicated by the duration of the hospital stay; the duration of pneumonia or diarrhea; the incidence of "postmeasles" croup or herpes stomatitis; and the need for a transfer to the Red Cross War Memorial Children's Hospital for intensive care. Pneumonia was defined as the presence of tachypnea (frequency of respiration >40 per minute) with retractions, crackles, or wheezes. Diarrhea was defined as the passage of four or more liquid stools a day. Measles croup was defined as croup presenting on or within a day of admission. Croup that developed subsequently was categorized as postmeasles.

Statistical Analysis

The data were analyzed by computer with the Epi-Info program (version 3, USD, Stone Mountain, Ga.). Categorical data[23] (e.g., the number of patients per group) were evaluated by the chi-square test, with Yates' correction for continuity applied routinely,[24] or by Fisher's exact test when the expected number in a cell was five or less.[24] Confidence intervals for the relative risks were calculated according to the method of Greenland and Robins.[25] Continuous data[23] (e.g., vitamin level) were compared by the nonparametric Kruskal–Wallis test.[23,24] All P values reported are two-tailed, with values of less than 0.05 considered statistically significant.

Results

Exclusion of Patients

Of 224 patients under 13 years of age who were admitted to the hospital with measles during the study, 35 were excluded from the trial. In 12 of these cases the rash was present for five or more days, in 2 vitamin A had previously been given, in 18 consent could not be obtained because the child was unaccompanied by a parent on admission, and in 3 the parents refused consent. Hence, 189 patients were entered in the trial. There were no exclusions for xerophthalmia or withdrawals after entry.

Base-Line Characteristics

The placebo and treatment groups were generally comparable (Tables 1 and 2), except that the patients in the vitamin A group were admitted about 12 hours earlier in terms of the duration of the rash and had lower serum levels of total protein and albumin than those in the placebo group. Two thirds of the children were 12 months old or younger (median, 10 months; range, 2 months to 5 years), and most were boys (58 percent). Blacks predominated (72 percent), and the remainder were of mixed race. The five white patients admitted with measles were excluded: consent was refused in the cases of two, and three were more than 13 years old. The hospital is open to all. Immunization and socioeconomic factors are thought to account for differences in racial makeup between the study population and the general population 14 years of age or

under in Cape Town (57 percent mixed race, 25 percent black, 18 percent white).[27] Heights were not measured for 11 patients. Height for age was below the fifth percentile in 52 children (29 percent) — a prevalence similar to that in the local reference population.[28] Weight for age (below the fifth percentile in 50 percent), and weight for height (below the fifth percentile in 39 percent) were considered to reflect short-term weight losses from measles[29,30] rather than preexisting acute protein-energy malnutrition, since that occurs in 1 percent or less of the local reference population.[28] A combination of pneumonia and diarrhea was the usual indication for hospital admission (64 percent). Diarrhea (16 percent), pneumonia (13 percent), or measles croup (7 percent) appearing as isolated symptoms precipitated the other admissions.

Table 2. Base-Line Blood and Serum Values, According to Treatment Group.

Characteristic*	No. of Patients	Placebo	Vitamin A
		mean (25th, 50th, and 75th percentile)	
Hemoglobin (g/dl)	177	10.73 (10, 10.6, 11.5)	10.78 (10, 10.5, 11.7)

Vitamin A (retinol) (μg/dl)	156	12.19 (7.7, 10.7, 14.4)	10.95 (6.7, 9.5, 12.6)
Age <2 yr	131	12.84 (11.4, 15.1, 46.5)	11.1 (6.7, 9.5, 12.4)
Age ≥2 yr‡	25	8.38 (7.1, 8.1, 10.5)	10.29 (6.4, 10.5, 13.6)
Hyporetinemia	143	68§	75§
Vitamin E (mg/liter)	156	7.94 (5.5, 7.8, 9.4)	6.84 (4.7, 6.8, 8.8)

*Reference values for the characteristics shown are as follows[26]: hemoglobin, 11.5 to 15.5 g per deciliter; hematocrit, 35 to 45 percent; leukocytes, 6 to 17×10^9 cells per liter; total protein, 62 to 80 g per liter; albumin, 35 to 50 g per liter; retinol-binding protein, 22 to 45 mg per liter; vitamin A (as retinol), 30 to 80 μg per deciliter; vitamin E (as alpha-tocopherol), 5.0 to 20 mg per liter. No reference values are given for lymphocytes because of considerable variation with age. RBP denotes retinol-binding protein. To convert grams of hemoglobin per deciliter to millimoles per liter, multiply by 0.6206; to convert micrograms of vitamin A per deciliter to micromoles per liter, multiply by 0.03491; and to convert milligrams of vitamin E per liter to micromoles per liter, multiply by 23.22.

†$P<0.05$ for the comparison between groups.

‡In the placebo group, the retinol level was significantly lower in children ≥2 years old than in those <2 years old ($P = 0.026$).

§Indicates the number of cases of hyporetinemia (serum retinol concentration <0.7 μmol per liter [20 μg per deciliter]).

No blood samples were obtained from 15 patients, and only partial results were available for another 19 (Table 2). Serum levels were low for total protein (mean [±SE], 56.2±0.7 g per liter), albumin (mean, 33.4±0.46 g per liter), retinol-binding protein (mean, 30.1±2.02 mg per liter), and vitamin A as retinol (mean, 0.405±0.021 μmol per liter [11.6±0.6 μg per deciliter]). Low levels of total protein principally reflect depressed serum albumin concentrations ($r^2 = 72.6$ percent, $P<0.001$). Serum retinol levels were below the lower limit of the normal range (0.7 μmol per liter [20 μg per deciliter]) in 92 percent of the children (143 of 156), and 46 percent (72) had levels below 0.35 μmol per liter (10 μg per deciliter), placing them at risk for xerophthalmia,[31] although no cases of this were observed. Vitamin E levels were in the normal range.

Outcome

The children who received vitamin A had markedly diminished mortality and morbidity (Table 3), with no clinically apparent adverse effects. Of the 12 children who died (6.3 percent), 10 were in the placebo group ($P = 0.046$). The children who died were 5 to 29 months of age, and seven were boys. Death occurred 3 to 32 days after admission (median, 10.5). Pneumonia[3,32] caused 10 deaths, and the two remaining children died after 15 and 32 days, respectively, of fulminant sepsis following chronic diarrhea and measles-induced kwashiorkor. Croup was present as an incidental finding in 5 of the 10 children who died of pneumonia.

Cases of pneumonia lasted almost twice as long in the placebo group as in the vitamin A group ($P<0.001$), and 66 percent of the children with chronic pneumonia (>10 days) were in the placebo group ($P = 0.008$). Similarly, diarrhea continued for a third longer in the placebo group ($P<0.001$), and 72 percent of the children with chronic diarrhea were in that group ($P = 0.023$). Postmeasles croup was more common in the placebo group ($P = 0.033$), as was herpes stomatitis ($P = 0.08$). Finally, the hospital stay of the survivors was shorter by a third in the vitamin A–treated group ($P = 0.004$).

Overall, 77 children had adverse outcomes (Table 3), of whom 52 were in the placebo group ($P = 0.004$). As compared with the children in the placebo group, the children treated with vitamin A were at lower relative risk for death (relative risk, 0.21; 95 percent confidence interval, 0.05 to 0.94), prolonged pneumonia ≥10 days (relative risk, 0.44; 95 percent confidence interval, 0.24 to 0.80), prolonged diarrhea ≥10 days (relative risk, 0.40; 95 percent confidence interval, 0.19 to 0.86), postmeasles croup (relative risk, 0.51; 95 percent confidence interval, 0.28 to 0.92), airway intervention (relative risk, 0.35; 95 percent confidence interval, 0.10 to 1.26), herpes stomatitis (relative risk, 0.23; 95 percent confidence interval, 0.05 to 1.06), and the need for intensive care (relative risk, 0.38; 95 percent confidence interval, 0.13 to 1.16). The overall risk for an adverse outcome in children treated with vitamin A was half that in the control group (relative risk, 0.51; 95 percent confidence interval, 0.35 to 0.74). Of the 77 children who had adverse outcomes, only 2 were ≥2 years of age ($P = 0.002$), and the risk in a child ≥2 years old was substantially lower than in

*In the columns representing the treatment groups, the values in italics are means, followed in parentheses by 25th percentiles, medians, and 75th percentiles. All other values are numbers of patients.

†Relative risk denotes the ratio of the incidence of an event in the vitamin A group to the incidence of the event in the placebo group. CI denotes confidence interval.

‡Defined as death, pneumonia ≥10 days in duration, diarrhea ≥10 days in duration, postmeasles croup, or transfer for intensive care.

§Refers to children who survived.

younger children (relative risk, 0.15; 95 percent confidence interval, 0.02 to 0.91). No child with a serum retinol concentration ≥0.7 μmol per liter (20 μg per deciliter) died, but the smallness of this group (n = 14) leaves the significance of the finding in doubt.

Discussion

The results of our randomized, controlled trial indicate a remarkable protective effect of vitamin A in severe measles, notwithstanding the provision of good general medical care and the presence of complicated advanced disease. Vitamin A reduced the death rate by more than half and the duration of pneumonia, diarrhea, and hospitalization by about one third. Vitamin A also appeared to reduce the incidence of herpes stomatitis and the need for intensive care. The consistency of benefit with respect to all measures of outcome is noteworthy, since mortality is not a sensitive criterion. Because of their reliance on mortality rates, previous studies of measles[5,6] lacked the statistical power to establish the benefit of vitamin A therapy.

The favorable response to vitamin A therapy may be understood in terms of the very high incidence (92 percent) of hyporetinemia in our patients (Table 2). Hyporetinemia implies a state of vitamin A deficiency at the tissue level, since there are virtually no peripheral-tissue stores of vitamin A except in the retina.[33-36] Serum retinol levels below 0.7 μmol per liter (20 μg per deciliter) appear to be inadequate for the body's biologic needs.[33] Oral vitamin A is absorbed well even in patients with diarrhea,[37] so the observed effects of treatment may reasonably be ascribed to correction of the tissue deficit of vitamin A. We do not know, however, whether the deficit was rectified by increases in the serum retinol concentration or by some other mechanism, since serum retinol levels were not measured after therapy.

Hyporetinemia appears almost invariable in children with severe measles,[8-11] as in this study, and the reduction in the serum retinol level is associated with increasingly severe disease.[11] Since many of these data come from populations in which nutritional vitamin A deficiency is a known problem,[8-10] it has been inferred that hyporetinemia in measles represents the exhaustion of hepatic stores.[6,7,20] There is a possible alternative mechanism, however. Hyporetinemia may occur in the presence of adequate hepatic stores of vitamin A when the stores are not mobilized fast enough to meet demand.[36] This has been found in fever, pneumonia, rheumatoid arthritis, hepatitis, acute tonsillitis, and rheumatic fever[36]; in protein-energy malnutrition[38]; and now also in measles.[8] Inadequate mobilization of hepatic stores may therefore underlie the hyporetinemia in children with severe measles from Kinshasa, Zaire,[11] and Cape Town, where nutritional vitamin A deficiency is uncommon. A study 25 years ago showed vitamin A deficiency to be rare in Cape Town, even in children with severe protein-energy malnutrition,[38] and it still appears to be rare. A search of the computer data-base listing of inpatients at our children's hospital, which predominantly serves the local underprivileged community, found only three instances of clinical vitamin A deficiency among 161,381 children admitted over a 13-year period, with no cases since 1985.

In view of the evidence that hyporetinemia may occur in the presence of adequate hepatic stores of vitamin A[38] and in populations not known to be deficient in vitamin A,[11] it would seem prudent to proceed on the assumption that previous nutritional adequacy may not ensure against the development of hyporetinemia in severe measles. For all children seriously ill with measles, vitamin A replacement should thus be provided at the dose given by Barclay et al.[6] (400,000 IU), which proved effective and safe in our study. A lower dose (100,000 to 200,000 IU) is recommended by the World Health Organization,[20] but its efficacy in measles has yet to be established.

It may be asked whether it is cost effective to advocate treatment with vitamin A for all children with

severe measles. Clearly, children under two years of age are at highest risk of an adverse outcome and derive the most benefit from vitamin A. When resources are scarce, such children should be given priority. In our study, however, half the children over two years of age were at risk of xerophthalmia because of serum retinol levels below 0.35 μmol per liter (10 μg per deciliter),[31] and hence they should have vitamin A prophylaxis. Thus, when resources permit, all children with severe measles should be given supplemental vitamin A.

We are indebted to many colleagues for constructive criticism; to Mr. R. Sayed, statistician to the Department of Community Health of the University of Cape Town for advice on study design and randomization procedures; to Ms. G. Joubert of the South African Medical Research Council, for assistance with data collection and preliminary analyses; to Glaxo (South Africa), for the donation of our computer; to the nursing staff of the City Hospital for Infectious Diseases for invaluable assistance and to the hospital's medical superintendent, Dr. P.J.W. Roux, for providing facilities; to Mr. A.F. Rodriques for searching the data base of patients of the Red Cross War Memorial Children's Hospital; to the medical superintendent, Dr. R.O. Simpson, for giving access to the data base; to the McCaul Bell Bequest of the Institute of Child Health, University of Cape Town, for a grant to Professor H. de V. Heese that provided funding for the assays of vitamins and retinol-binding protein; and to Ms. Frances Pocock for performing these assays in the Institute laboratory.

Routine high-dose vitamin A therapy for children hospitalized with measles.

Hussey GD[1], Klein M.

Author information

Abstract

Measles is without specific therapy and remains important globally as a cause of childhood death. In controlled studies, high-dose vitamin A therapy (Hi-VAT)--with 400,000 IU vitamin A--has been demonstrated to markedly reduce measles-associated morbidity and mortality. We performed a retrospective study of the hospital records of 1720 children < 15 years of age who were hospitalized for measles, to determine the extent to which these findings, in research settings, are applicable to the case management of measles under conditions of routine hospital practice. The outcomes were studied of children hospitalized during two non-consecutive 2 year periods (1985-6 and 1989-90). A policy of Hi-VAT for all children hospitalized with measles was started during the intervening period. As compared with the group of children on standard therapy (n = 1061), children receiving Hi-VAT (n = 651) had a shorter hospital stay (mean 10 versus 13 days; P < 0.001), a lower requirement for intensive care (4.3 versus 10.5 per cent; P < 0.001), and a lower death rate (1.6 versus 5 per cent; P < 0.001). No adverse effects of Hi-VAT therapy were observed. We conclude that a policy of high dose oral vitamin A (400,000 IU) supplementation in measles provides benefits which are equivalent to those previously observed only in controlled research trials, that it is highly cost effective, and that it should form part of the routine case management of all children hospitalized with measles.

Abstract

Children with no known prior vitamin A deficiency exhibited a significant decline in their serum retinol levels during the acute phase of measles. This decline in circulating retinol was associated with increased duration of fever, higher hospitalization rates, and decreased antibody titers.

Measles severity and serum retinol (vitamin A) concentration among children in the United States.

Butler JC[1], Havens PL, Sowell AL, Huff DL, Peterson DE, Day SE, Chusid MJ, Bennin RA, Circo R, Davis JP.

Author information

Abstract

BACKGROUND: Studies in developing countries have shown that children with measles have low serum retinol concentrations and that lower retinol levels are associated with measles-related mortality. Vitamin A therapy has been shown to reduce mortality among African children with acute measles.

OBJECTIVES: To determine whether serum retinol concentration is low among children with measles in the United States and to determine whether retinol concentration is associated with illness severity.

SETTING: Pediatric referral hospital and clinic in Milwaukee, WI, during the measles outbreak of 1989-1990.

PATIENTS: One hundred fourteen patients < or = 5 years of age evaluated for serologically confirmed measles with serum obtained within 5 days following rash onset.

METHODS: Serum retinol concentration was determined by high-performance liquid chromatography. Clinical data were collected by hospital record review. A modified Pediatric Risk of Mortality (PRISM) score was used to assess physiologic instability as a measure of illness severity.

RESULTS: Retinol concentrations ranged from 0.25 to 1.18 mumol/L (median 0.58 mumol/L); 82 (72%) patients had low retinol concentration (< or = 0.70 mumol/L). Median retinol concentrations were lower among hospitalized patients (0.56 vs 0.70, P = .006) and patients with pneumonia (0.52 vs 0.64, P = .02) but higher among children with otitis media (0.63 vs 0.54, P = .01). Higher modified PRISM scores, reflecting greater physiologic instability, were associated with lower retinol concentration (beta coefficient -.0147, P = .025). In multivariate analysis, higher modified PRISM scores were associated with lower retinol concentration (beta coefficient -.0144, P = .025) even after controlling for hospitalization, presence of complications, race, age, receipt of Aid to Families With Dependent Children, gender, and interval from rash onset until serum was collected.

CONCLUSIONS: Among these children with measles in an urban United States community, retinol concentrations were depressed, and the degree of depression was associated with illness severity. Vitamin A therapy should be considered for children with measles in the United States who require hospitalization.

Persistent measles infection in malnourished children.

Dossetor J, Whittle HC, Greenwood BM.

Abstract

Thirty malnourished and 25 well-nourished children were studied six to 31 days after the onset of a measles rash. Evidence of the virus was found in 40% of the malnourished children but in none of the well-nourished controls. Giant cells were found in the nasal secretions of five out of 17 malnourished children and measles antigen was detected in the lymphocytes of eight out of 28. The malnourished children showed depressed cell-mediated immunity to measles and candida antigens and a low response to meningococcal vaccine. Fifteen died from intercurrent infections. Malnutrition was thought to have depressed the immune response in these children, resulting in a severe and prolonged attack of measles. This, in turn, led to further damage to the immune system and more severe malnutrition. Thus these children were made susceptible to intercurrent infection.

Vitamin A for the treatment of children with measles--a systematic review.

D'Souza RM[1], D'Souza R.

Author information

1 National Centre for Epidemiology and Population Health, The Australian National University, Canberra, Australia. rennie.dsouza@anu.edu.au

Abstract

Vitamin A deficiency is a recognized risk factor for severe measles. WHO and UNICEF have recommended vitamin A for the treatment of measles but there are children still dying from measles. A systematic review, including the use of meta-analysis was done of randomized controlled trials comparing vitamin A with placebo obtained from a systematic search of the medical literature to determine whether vitamin A prevents mortality and pneumonia-specific mortality in children with measles. We identified five trials conducted in Africa, four in hospitals and one in a community that met the inclusion criteria. There were 445 children aged 6 months to 13 years supplemented with vitamin A and 478 with placebo. There was a 39 per cent reduction in overall mortality when vitamin A was used for the treatment of measles but this was not statistically significant (relative risk 0.61; 95 per cent confidence interval 0.32-1.12). When stratified by dose, 200 000 IU of vitamin A given for 2 days was associated with a reduction in overall mortality (0.36, 0.14-0.82) and pneumonia-specific mortality (0.33, 0.08-0.92) in hospitalized children in areas with high case fatality. Greater reduction in mortality was observed in children under the age of 2 years (0.17, 0.03-0.61). On the other hand, a single dose of 200 000 IU of vitamin A was not associated with reduced mortality (1.25, 0.48-3.1). There were no trials comparing a single dose with two doses of vitamin A. There were not enough studies to separate out the individual effects of age, dose, formulation, hospitalization and case fatality in the study area. We conclude that 200 000 IU of vitamin A repeated on 2 days should be used for the treatment of measles as recommended by WHO in children admitted to hospitals in areas where the case fatality is high.

Vitamin A supplements for children could save 600,000 lives a year, experts predict

Date: August 25, 2011

Source: BMJ-British Medical Journal

Summary: Children in low and middle income countries should be given vitamin A supplements to prevent death and illness, a new study concludes.

FULL STORY

Children in low and middle income countries should be given vitamin A supplements to prevent death and illness, concludes a study published online in the British Medical Journal.

The researchers argue that the effectiveness of vitamin A supplementation is now so well-established that further trials would be unethical, and they urge policymakers to provide supplements for all children at risk of deficiency.

Vitamin A is an essential nutrient that must be obtained through diet. Vitamin A deficiency in children increases vulnerability to infections like diarrhea and measles and may also lead to blindness. Globally, the World Health Organisation estimates that 190 million children under the age of 5 may be vitamin A deficient. But, despite widespread efforts, vitamin A programmes do not reach all children who could benefit.

So a team of researchers based in the UK and Pakistan analysed the results of 43 trials of vitamin A supplementation involving over 200,000 children aged 6 months to 5 years. Differences in study design and quality were taken into account to minimise bias.

They found vitamin A supplements reduced child mortality by 24% in low and middle income countries. It may also reduce mortality and disability by preventing measles, diarrhea and vision problems, including night blindness.

The authors say that, if the risk of death for 190 million vitamin A deficient children were reduced by 24%, over 600,000 lives would be saved each year and 20 million disability-adjusted life years (a measure of quantity and quality of life) would be gained.

Based on these results, the authors strongly recommend supplementation for children under 5 in areas at risk of vitamin A deficiency. They conclude: "The evidence for vitamin A is compelling and clear. Further trials comparing vitamin A with placebo would be unethical."

This view is supported in an accompanying editorial by two experts at Harvard School of Public Health, who say "effort should now focus on finding ways to sustain this important child survival initiative and fine tune it to maximise the number of lives saved."

Abstract

Objective To determine if vitamin A supplementation is associated with reductions in mortality and morbidity in children aged 6 months to 5 years.

Design Systematic review and meta-analysis. Two reviewers independently assessed studies for inclusion. Data were double extracted; discrepancies were resolved by discussion. Meta-analyses were performed for mortality, illness, vision, and side effects.

Data sources Cochrane Central Register of Controlled Trials (CENTRAL) in the Cochrane Library, Medline, Embase, Global Health, Latin American and Caribbean Health Sciences, metaRegister of Controlled Trials, and African Index Medicus. Databases were searched to April 2010 without restriction by language or publication status.

Eligibility criteria for selecting studies Randomised trials of synthetic oral vitamin A supplements in children aged 6 months to 5 years. Studies of children with current illness (such as diarrhoea, measles, and HIV), studies of children in hospital, and studies of food fortification or β carotene were excluded.

Results 43 trials with about 215 633 children were included. Seventeen trials including 194 483 participants reported a 24% reduction in all cause mortality (rate ratio=0.76, 95% confidence interval 0.69 to 0.83). Seven trials reported a 28% reduction in mortality associated with diarrhoea (0.72, 0.57 to 0.91). Vitamin A supplementation was associated with a reduced incidence of diarrhoea (0.85, 0.82 to 0.87) and measles (0.50, 0.37 to 0.67) and a reduced prevalence of vision problems, including night blindness (0.32, 0.21 to 0.50) and xerophthalmia (0.31, 0.22 to 0.45). Three trials reported an increased risk of vomiting within the first 48 hours of supplementation (2.75, 1.81 to 4.19).

Vitamin A supplementation reduced incidence of measles by 50% (37%-67%).

Conclusions Vitamin A supplementation is associated with large reductions in mortality, morbidity, and vision problems in a range of settings, and these results cannot be explained by bias. Further placebo controlled trials of vitamin A supplementation in children between 6 and 59 months of age are not required. However, there is a need for further studies comparing different doses and delivery mechanisms (for example, fortification). Until other sources are available, vitamin A supplements should be given to all children at risk of deficiency, particularly in low and middle income countries.

Introduction

Vitamin A refers to a subclass of retinoic acids[1] long understood to help regulate immune function and to reduce morbidity of infectious diseases.[2] Vitamin A is required for normal functioning of the visual system, maintenance of cell function for growth, epithelial integrity, production of red blood cells, immunity, and reproduction.[3] Different forms of vitamin A include β carotene, which is found in plants, and preformed vitamin A, which is found in animal sources. Vitamin A is an essential nutrient that cannot be synthesised so it must be obtained through diet.[1]

Vitamin A deficiency increases vulnerability to a range of illnesses including diarrhoea, measles, and respiratory infections.[3 4] These are leading causes of mortality among children in low and middle income countries,[5] where risk of infection and risk of mortality can be compounded by coexisting undernutrition.[6] The bioavailability of provitamin A carotenoids in fruit and vegetables is lower than once believed,[7 8] and it is difficult for children to fulfil their daily requirements through plant foods alone. Consequently, vitamin A deficiency is

common among children whose families cannot afford eggs and dairy products.

Preformed vitamin A (retinol, retinal, retinoic acid, and retinyl esters) is the most active in humans; it is usually used in supplements in the form of retinyl esters.[1 3] High intake of synthetic vitamin A over a prolonged period can lead to toxicity,[9] but toxicity from food sources is rare. Periodic supplementation should not cause serious adverse effects.[10]

Previous meta-analyses suggested that vitamin A supplementation for children in developing countries is associated with up to 30% reductions in mortality,[11-13] especially deaths from diarrhoea and measles. The World Health Organization has long recommended vitamin A supplementation for children aged under 5 and for pregnant and breastfeeding mothers.[14] The Countdown to 2015 identified 68 "priority countries" in which over 90% of the world's maternal and childhood deaths occur[15]; the programme aims to hold governments accountable for their commitments to Millennium Development Goals. Vitamin A is now being provided in many low and middle income countries with coverage rates of 86%.[15] Nonetheless, some critics have questioned the value and effectiveness of vitamin A supplementation programmes, and several studies have been conducted since initial recommendations were made.[16 17]

We undertook a review to synthesise all available evidence for vitamin A supplementation in children aged 6 months to 5 years, adding to previous reviews by investigating effects on mortality and the illnesses that lead to death. By investigating all effects in the same review, we provided current estimates of treatment effects and identified potential pathways through which vitamin A supplementation might reduce mortality. A complete protocol was peer reviewed and published by the Cochrane Collaboration, and the review is available in the Cochrane Library.[18]

Methods

We evaluated the effect of prophylactic synthetic oral vitamin A supplementation compared with no treatment or placebo. We planned to conduct five subgroup analyses:

- Dose: WHO recommended dose (up to 100 000 IU for children aged 6-11 months and 200 000 IU for children aged 1-5 years) *v* lower and higher doses
- Frequency: high (doses within 6 months) *v* low (1 dose or ≥6 month interval)
- Location: by continent
- Age: 6-12 months *v* 1-5 years
- Sex: boys *v* girls.

Eligibility criteria

Types of trials—Randomised controlled trials including cluster trials and factorial trials were included irrespective of publication status or language.

Types of participants—At the time of recruitment, children had to be aged 6 months to 5 years and apparently healthy. Children in hospital at the time of recruitment were excluded.

Types of interventions—Included studies examined synthetic oral vitamin A supplementation compared with no treatment or placebo, irrespective of dose or frequency. Studies of food fortification and β carotene supplementation were excluded as their effects can differ.

Types of outcome measures

Primary—We examined all cause mortality at the longest follow-up. We also analysed outcomes within the first year and more than one year after supplementation.

Secondary—We analysed cause specific mortality from diarrhoea, lower respiratory tract infection, measles, and meningitis. We compared the incidence and prevalence of diarrhoea, lower respiratory tract infection, measles, malaria, meningitis, Bitot's spots, night blindness, and xerophthalmia. Adverse events were noted and analysed when possible (vomiting and bulging fontanelle). Finally, we examined vitamin A status (serum retinol) as a continuous and dichotomous outcome.

Search strategy

We searched the Cochrane Central Register of Controlled Trials (CENTRAL 2010, issue 2), Medline (see box), Embase, Global Health, Latin American Database (LILACS), metaRegister of Controlled Trials, and African Index Medicus (see appendix 1 on bmj.com). All searches were conducted on 27 April 2010. To identify ongoing and unpublished trials, we used the WHO international clinical trials registry, which searches multiple trial registries. Reference lists of reviews, included studies, and excluded studies were searched for additional citations. We contacted organisations and researchers by email and by phone. Two authors (from AI, KH, and MYY) independently screened abstracts and resolved differences with a third author (EMW).

Assessment of bias

Studies were assessed with the Cochrane Collaboration's risk of bias tool.[19] Two authors rated each study for risk of bias from sequence generation (was the method truly random?), allocation concealment (before enrolment, were participants' group assignments disguised?), blinding of participants, assessors, and providers (was assignment adequately disguised after randomisation?), selective outcome reporting (were all outcome measures reported?), and incomplete data (do the results account for all participants randomised?). Risk of bias for each domain was rated as high (seriously weakens confidence in the results), low (unlikely to seriously alter the results), or unclear. Discrepancies were resolved through discussion. The primary analysis was repeated without studies at high risk of bias for sequence generation.

Data management

Two independent people, at least one of whom was an author, completed data extraction and assessments of risk of bias online with Distiller software.[20] We collected data on the time points and measures (both collected and reported) and recruitment, inclusion/exclusion criteria, co-interventions, dose, frequency, duration, age, sex, setting, and location.

Statistical analysis

For continuous outcomes, we calculated the standardised mean difference, Hedges' g.[21] For dichotomous outcomes, we calculated an overall risk ratio. For incidence data, risk ratio (events per child) and rate ratio (events per child year) were combined because these ratios use the same scale and can be interpreted in the same way for these studies (the duration of studies was short and there was no interaction between the intervention and time at risk). All outcomes are reported with 95% confidence intervals, and overall effects are weighted by the inverse of variance with a fixed effect model. In the case of

cluster randomised controlled trials, we used adjusted estimates reported by the authors. Where results did not control for clustering, we contacted authors to request the intracluster correlation coefficient. If authors were unable to provide this, we used design effects calculated previously[11] to calculate it using Cochrane methods.[19] For estimated values, we conducted sensitivity analyses using larger and smaller design effects to determine if the results were robust.

Missing data were noted for each outcome. When the numbers of dropouts were not reported, we contacted the authors. When analyses were reported for completers as well as controlled for dropouts (for example, imputed with regression methods), we used the latter.

Statistical heterogeneity was assessed by visual inspection of forest plots, by performing χ^2 tests (assessing the P value), and by calculating the I^2 statistic,[22 23] which describes the percentage of observed heterogeneity that would not be expected by chance. If the P value was less than 0.10 and I^2 exceeded 50%, we considered heterogeneity to be substantial. In subgroup analyses, we tested differences between groups with χ^2. To assess the possibility of small study bias, we compared random effects estimates with fixed effects estimates, drew funnel plots for outcomes with 10 or more studies, and conducted a trim and fill analysis,[24] which yields an effect adjusted for funnel plot asymmetry. Meta-analysis was conducted with RevMan[25] and Biostat CMA (comprehensive meta-analysis)[26] and a summary of results was prepared with the GRADE system.[27]

Results

Trial flow

We included 43 trials[28-69] reported in 90 papers; 39 (90%) reported data that could be included in a meta-analysis (fig 1⇓). The others reported outcomes that were not relevant to the review[35] and data that were not available by group[43] or were incomplete.[62 66] Post hoc, we included two studies in which participants were assigned using quasi-random methods (alternating assignment) as described below.[41 65]

Eight trials nearly met the inclusion criteria but were excluded because they were not randomised controlled trials,[70-73] were designed to treat diarrhoea[74] or Bitot's spots,[75] focused on children with HIV, [76] or did not include an eligible comparison.[77]

Two trials could not be assessed at this time. One including 36 children could not be located and is unlikely to affect the results.[78] One completed trial, the deworming and vitamin A (DEVTA) trial, seems likely to meet the eligibility criteria and could be included in further updates of this review.[79] To assess how the results of that trial could affect the conclusions of our review, we conducted a sensitivity analysis for the primary outcome.

Study characteristics

Trials included 215 633 participants with a median sample size of 480, ranging from 35[66] to over 29 000.[63] The 39 trials that were analysed included 215 043 participants (99.8% of children included in the review).

Of the 43 included trials, 37 compared vitamin A supplementation with placebo. Four used factorial designs, combining vitamin A supplementation with other treatments such as zinc[46 51 62] or deworming.[55] In one trial,[51] raw data were not available and we could not identify outcome data for an eligible comparison. Different doses were combined for the main analysis in one trial.[40]

The median of the mean ages was 30.5 months. Most trials assigned equal numbers of boys and girls; three studies favoured boys by more than 10%.[45 54 57] When trials reported outcomes at multiple time points, we analysed the longest follow-up; most studies lasted about one year. Table 1⇓ describes characteristics for individual studies, and table 2⇓ shows counts for subgroup characteristics.

Risk of bias

Figure 2 shows the risk of bias ratings[19] for each trial.⇓ Three trials were at high risk of bias for sequence generation (not truly random), and these included 41 139 participants.[29 41 65] In two

quasi-random studies (included post hoc), the authors and the Cochrane editors agreed that the methods of assignment had the desirable characteristics of randomisation and were at no greater risk of bias than other included studies. Only one study was at high risk of bias because of inadequate allocation concealment, but concealment of the allocation sequence was not sufficiently described in 27 trials.

Lack of blinding of assessors created a high risk of bias in only two studies, but it was unclear if assessors were blind in 14 trials. Two studies were at high risk of bias for failing to blind project staff, and 13 trials were unclear on this issue. At the trial level, nine were at high risk of bias for missing data and 12 were unclear, though missing data for the primary outcome was not a concern.

Only four studies seemed to be completely free from selective outcome reporting. It was unclear if 24 trials reported all outcomes, but the primary outcome (mortality) was known for almost all participants in the review. To test for bias, the primary analysis was repeated without studies at high risk of bias for sequence generation.

Quantitative data synthesis

All cause mortality

Mortality (fig 3⇓) was reported in 17 trials including 194 483 children (90% of the children in the review); one reported no events and was not analysed.[45] Thus, 16 trials were included in the primary meta-analysis. Two studies[41 65] randomised households, and we treated them as if they had randomised individuals. Previously reported design effects[11] were used to calculate intracluster correlation coefficients for six cluster randomised studies.[37 52 56 63 68 69] The coefficients were consistent, and we imputed an intracluster correlation coefficient of 0.002 for all studies in which clustering was not considered in the original analysis. A sensitivity analysis was conducted for all cause mortality with coefficients of 0 and 0.01 for those studies in which the mean design effect was estimated.

Vitamin A was associated with a 24% reduction in all cause mortality (0.76, 95% confidence interval 0.69 to 0.83; fig 3), though there was moderate heterogeneity (χ^2=29.10, df=15, P=0.02; I^2=48%). Only five trials[36 38 48 56 68] (7% of trials) measured mortality after 13 months, and the effect was similar (0.75, 0.64 to 0.88) with substantial and significant heterogeneity (χ^2=9.29, df=4, P=0.05; I^2=57%).

We then added a study awaiting assessment to the analysis.[79] In an analysis of 17 trials, this study (the deworming and vitamin A trial) accounted for 65.2% of the combined effect (fig 4⇓), which remained significant (0.88, 0.84 to 0.94) with substantial and significant heterogeneity (χ^2=44.31, df=16, P<0.001; I^2=64%). Though the benefit of vitamin A decreased by half (24% to 12%), the result remained clinically important. As we were unable to assess the trial, we cannot explain this substantially different result; its impacts on the conclusions of this review are considered below.

Of those in the main analysis, 10 trials were conducted in Asia, five in Africa, and one in Latin America. There was no clear difference (P=0.12) between the Asia subgroup (0.69, 0.61 to 0.79) and the Africa subgroup (0.85, 0.73 to 0.98), though the Latin American trial reported no effect (1.00, 0.14 to 7.08). We planned to compare trials in urban and rural areas, but only two urban trials reported the primary outcome; an analysis comparing 1982 and 192 501 participants would be difficult to interpret.

Four trials reported separate effects for children aged 6-12 months (0.59, 0.43 to 0.82) and children aged 1-5 years (0.68, 0.57 to 0.82); the subgroups did not differ significantly (P=0.46). Five trials reported separate effects for boys (0.80, 0.66 to 0.97) and girls (0.79, 0.65 to 0.95), which were not significantly different (P=0.89). Notably, effects for sex and age subgroups are all larger than the overall result, and these results should be interpreted with caution.

Only one trial providing small frequent doses reported mortality data, and the effects were larger (0.46, 0.30 to 0.71) than the effects for the WHO recommended dose delivered every four to six months (0.81, 0.72 to 0.90) or the recommended dose delivered once (0.66, 0.52 to 0.83). Differences between subgroups were significant (P=0.02), but only the greater effect for small frequent doses seems clinically plausible (fig 5⇓).

Of the trials at high risk of bias from sequence generation, only one contributed to primary analysis, and it reported no effect (1.06, 0.82 to 1.37), indicating that these trials were not likely to inflate the combined effect.

The primary analysis was repeated with a random effects model, and the overall estimate was slightly larger; thus, heterogeneity is partially explained by small studies reporting larger effects (0.71, 0.61 to 0.84), which could be related to bias or to clinical differences (such as better implementation in small trials). We drew a funnel plot and conducted a trim and fill analysis (fig 6⇓). There was some evidence of asymmetry (five studies trimmed), but the overall effect was strongly influenced by five studies that accounted for over 80% of the weighted mean, and there was no effect of replacing missing studies (adjusted value rate ratio=0.80, 0.73 to 0.87).

We also conducted a sensitivity analysis to determine if the intracluster correlation coefficients used to adjust for clustering influenced the overall effect. The size of the effect was slightly smaller when these trials were treated as if they had randomised individuals (0.81, 0.75 to 0.89) and was unchanged when we increased the coefficient to 0.01 (0.75, 0.68 to 0.83). Adjusting three studies for which the intracluster correlation coefficients was unknown did not affect our conclusions; further inflating their standard errors would increase the size of the overall effect.

Cause specific mortality

Vitamin A supplementation was associated with a 27% reduction in deaths from diarrhoea. Differences in deaths from measles and meningitis were not significant (table 3⇓).

Morbidities

Morbidity was measured in different ways, and we combined all available data whenever possible. For example, for diarrhoea we included all types of diarrhoea (mild, moderate, and severe). Pneumonia and lower respiratory tract infection outcomes were combined post hoc because pneumonia is a type of lower respiratory tract infection and many studies did not have complete diagnostic information.

Overall, there was a 15% decrease in diarrhoea incidence (fig 7⇓) and a 50% decrease in incidence of measles (fig 8⇓); heterogeneity in the former analysis was substantial, but heterogeneity in the second was not important. Only one trial reported incidence of malaria, which showed a reduction, and effects on lower respiratory infections were not significant (table 3⇓). Few studies reported prevalence data; results for diarrhoea and malaria were not significant, and there were no data for measles.

Vision

Evidence for vision outcomes was based on a small number of small studies. The available studies suggest a large reduction in the incidence and prevalence of night blindness and a large reduction in the prevalence of xerophthalmia, but effects on Bitot's spots and the incidence of xerophthalmia were not significant (table 4⇓).

Vitamin A deficiency

Serum concentrations were measured in a small number of small studies. These suggest that vitamin A supplementation reduces the proportion of children who are deficient and increases vitamin A serum concentrations (table 4⇓), but heterogeneity was substantial. These results could be influenced by bias, and serum concentrations might be a poor indicator of vitamin A status.

Adverse events

Three trials reported that high doses of vitamin A triple the risk of vomiting within 48 hours. Results for fontanelle side effects were not significant in one study (table 4), and two studies that measured the outcome could not be analysed.

Discussion

Comparable with previous reviews, this review shows that vitamin A supplementation is associated with large and important reductions in mortality for children in low and middle income countries. This adds substantively to previous reviews[11-13] in providing a plausible pathway and indicating that vitamin A supplementation reduces the incidence of and mortality from diarrhoea and measles. Vitamin A also reduces precursors to blindness. While there was a slight increase in the risk of vomiting within 48 hours, there was no evidence of serious adverse events as a result of periodic supplementation. Most trials did not measure vitamin A serum concentrations at baseline as children are unlikely to experience serious harm under these conditions; continuous supplementation, however, might lead to toxicity and cause more severe side effects. It is unclear if smaller more frequent doses would lead to the same minor side effects observed in this review.[9]

Vitamin A deficiency is common during childhood in many low and middle income countries, even among populations whose diets rely heavily on vegetables and fruits.[80] The reasons are multiple and include widespread maternal undernutrition, poor dietary quality, and losses during diarrhoea.[81 82] WHO estimates that 122 countries have a moderate to severe public health problem.[83]

Strengths and limitations

For the primary outcome, the evidence in this review is strong. Sixteen studies were analysed, which included a large number of children. Subgroup and sensitivity analyses show that the result is robust and the effects of bias were not important.

For the primary outcome, the quality of the evidence was "high" on the GRADE scale[27]—that is, further trials are unlikely to change the conclusion that vitamin A supplementation has a large and significant effect (table 3). It seems unlikely that the primary outcome is significantly overestimated because of bias from any source. Almost all studies were randomised with appropriate methods for sequence generation, and allocation was well concealed. It was easy to blind participants and providers, and most trials reported that people were unaware of the treatments being provided. Furthermore, lack of blinding might underestimate rather than overestimate effects—for example, a teacher might give extra food to a child receiving a placebo. Failure to blind assessors is unlikely to influence mortality data. Risks of selective outcome reporting and publication bias are low; the primary analysis included nearly all participants who had been randomised, and all studies large enough to make a difference in this analysis are probably known.

Two trials at high risk of bias for sequence generation were included post hoc, but steps to maintain allocation concealment and blinding minimised the possibility that participants were treated differently between groups. In the first, participants were assigned alternately by household.[41] The second used a random starting point and alternating distribution of red or green pills; the manufacturer held the code until the study was completed.[65] The decision to include these studies was made before data were extracted, and the one study that contributed to the primary outcome[41] reported no effect (1.06, 0.82 to 1.37). The decision to include these studies did not result in an overestimation of the primary outcome.

This review makes an important contribution by identifying several pathways though which vitamin A could reduce mortality. Much of the reduction in all cause mortality is probably explained by reductions in death from diarrhoea and measles, which are leading contributors to child mortality in low and middle income countries.[5] This hypothesis is strengthened by a review indicating that vitamin A supplementation prevents acute diarrhoea from becoming chronic.[84] Though the overall effect for mortality from measles was not significant, the trend was consistent with the overall results, and the therapeutic effects of vitamin A supplementation for measles are well established.[78]

For the secondary outcomes, the quality of the evidence was variable on the GRADE scale (tables 3 and 4), though evidence for measles incidence was high quality. We downgraded ratings for diarrhoea and measles mortality to "moderate" because of uncertainty about the size of the effects; these results are consistent with other findings and consistent with biological mechanisms through which vitamin A supplementation could cause an overall reduction in mortality.

In general, large studies examined effects on mortality while small studies measured illness, vision, and vitamin A serum concentrations. A few studies measured growth, though we did not include this as an outcome. Different outcomes are appropriate for studies with different purposes, but many secondary analyses include only a small proportion of the participants in the review. Recent evidence suggests that the prevalence of selective reporting of outcomes is high and that this might substantially bias systematic reviews.[85 86] If outcomes were reported selectively, addition of unreported data might influence the observed effects in some secondary analyses; we have more confidence in the internal validity of the primary outcome than the secondary outcomes.

Secondary outcomes also have less external validity than the primary analysis, and differences in the size of included studies could mask differences in the size of the analyses. For example, the primary analysis includes 16 trials while analyses for incidence of diarrhoea and serum concentration include 12 and 13 trials. Only five trials appear in both the primary analysis and the diarrhoea analysis, and only three appear in both the primary and serum analyses. While the primary outcome includes 194 483 participants (90% of those randomised), the analysis of incidence of diarrhoea includes only 37 710 (17%) and the serum analysis includes 6623 (that is, less than 3% of participants in the review). To draw attention to these differences

in external validity and risk of bias, tables 3 and 4 include the number of participants in each analysis as a percentage of those randomised.[87]

Comparison with earlier reviews

Landmark reviews of vitamin A for children appeared in 1993.[11 13] Since then, nine studies contributing 30% of the children in this review have improved the quality of the evidence for vitamin A supplementation in children aged under 5 years.

For the primary outcome, we conducted a cumulative meta-analysis (fig 9⇓) to show how the effect has shifted with the addition of studies over time. That is, each point on the plot shows the combined effect of the new study and all studies reported before it, and the weight is the combined weight of all studies up to that time. Eight trials were included in a 1993 review,[11] which reported a 23% reduction in all cause mortality (0.77, 0.70 to 0.86). Eight trials were added to this analysis (one additional trial reported no events), and the overall estimate has changed by 1%. The overall effect is not meaningfully different from the result of the first trial published in 1986. Therefore, this review confirms that previous estimates remain valid, finding little evidence of secular trends.

Supplementation in other populations is more controversial. A recent review of vitamin A supplementation for children aged under 6 months found no overall effect, but differences between regional subgroups might have been important.[88]

Comparison with the deworming and vitamin A (DEVTA) trial

The most important qualification of these findings is that a large study, awaiting assessment, found no benefit of vitamin A supplementation. Some reviews have found only fair agreement between the results of meta-analyses and the results of large trials[89]; in extreme cases, large trials might indicate that the combined results of smaller trials are incorrect in magnitude or direction.[90] When the results of large trials differ from the results of small trials, commonly used methods for meta-analysis could be inappropriate.[91] All things being equal (such as risk of bias and implementation), researchers and clinicians have been advised to trust large simple trials rather than meta-analyses of small trials.[92 93]

The deworming and vitamin (DEVTA) trial is the largest randomised controlled trial ever conducted, including about a million children in 72 clusters, more than four times the number of children in this review. The trial registration describes a factorial study comparing deworming and vitamin A, which was delivered every six months for two years.[79] The study began in 1999 and recruitment closed in 2004. The authors were contacted several times before our review was completed, but they did not provide information about the conduct of the study. We are unaware of any published results. We were therefore unable to assess eligibility, potential risk of bias, implementation of the intervention, or the generalisability of results. The authors did provide an early analysis of the primary outcome (rate ratio=0.96, 0.89 to 1.03), as well as analyses of cause specific mortality and vitamin A serum concentration.

Details that might explain differences between DEVTA and our review were not available, but we find it unlikely that the results of our review can be explained by small study bias. Small studies could differ from mega-trials, but five trials in this review included more than 20 000 participants and nine included more than 10 000 participants. Furthermore, when the mortality data for DEVTA are included, results of the primary analysis remain significant with a fixed effect model, and that effect remains clinically meaningful.

Heterogeneity

Statistical heterogeneity suggests there might be differences in the effects of vitamin A supplementation across settings and populations, and we conducted prespecified subgroup analyses for all analyses with 10 or more studies.

Trials were conducted in 18 countries. As described above, vitamin A supplementation was associated with significant reductions in mortality in both Asia and Africa. While the difference between subgroups for the primary outcome was not significant, biochemical concentrations of vitamin A seem lower in Asia than in Africa,[83] and our results are consistent with the hypothesis that the benefits of supplementation in Asia might be greater.[94]

For ethical reasons, some trials provided supplements to all children with symptoms of vitamin A deficiency (such as Bitot's spots). Exclusion of such children limits the magnitude of effects on vision outcomes, and such restrictions could contribute to observed heterogeneity across other outcomes in this review. Universal supplementation could result in larger benefits than those reported here.

A non-representative subset of studies reported data by age and sex, but these comparisons cannot be interpreted meaningfully except insofar as vitamin A supplementation was associated with significant reductions in mortality for all subgroups. All studies reporting the primary outcome used the standard dose recommended by WHO (table 2), except for one.[52] While differences between these subgroups were significant, the results might be a statistical artefact; it is possible that small frequent doses will lead to large reductions in mortality, but it seems unlikely that a single supplement is more effective than multiple supplements of the same dose.

Though we did not find evidence of specific contributors to heterogeneity in this review, effects might differ according to baseline vitamin A status, the availability of other nutrients, or the prevalence of disease—for example, concomitant nutrient deficiencies could impair the bioavailability of vitamin A supplementation[95] and differences in the prevalence of pathogens, sanitation, immunisation, and access to healthcare could affect the relative impact of vitamin A supplementation. Heterogeneity might be related to differences in the implementation of interventions, details of which are routinely under-reported in trials.[96] For example, it is essential that providers distribute capsules effectively, that capsules have been stored properly and remain active, and that children ingest the supplements.

Subgroup analyses in this review were limited by the available data, and meta-analyses of group level data to explore individual level moderators should be interpreted with caution. Further analyses with individual patient data from randomised controlled trials and observational studies would be more informative.

Implications for policy

Vitamin A deficiency is a common condition that contributes to illness, blindness, and death; supplements can reduce these problems for children aged under 5 in low and middle income countries. National and regional supplementation programmes could be among the world's most cost effective public health interventions.[97] If the risk of death for 190 million children deficient in vitamin A were reduced by 24%, estimates from

2008 suggest that over 600 000 lives could be saved each year[98] and 20 million disability adjusted life years would be gained.[99]

Although vitamin A supplementation has been available in many countries for over a decade, direct evidence for its contribution to reducing child mortality is not available. Many countries have experienced significant reductions in child mortality,[5 100] and vitamin A supplementation programmes might have contributed to these declines.

Supplementation responds to an immediate need, but, in the long term, good nutrition requires reliable access to various fresh foods. Fortification, food distribution programmes, and horticultural developments might provide more permanent solutions. For example, growers could increase access to agricultural products like the orange fleshed sweet potato.[101] Vitamin A could be added to rice, though fortification programmes must minimise risk of toxicity. Until such long term solutions are in place, supplementation should continue. As access to vitamin A increases, it will be important to continue to identify at risk groups and to deliver supplements to them.

Our review suggests potential pathways through which vitamin A supplementation reduces mortality. Increased vaccination against measles and other diseases will reduce the effect of vitamin A supplementation if its primary effect is to prevent infection; widespread supplementation, however, will remain important because vitamin A affects other systems—for example, supplementation can prevent blindness.

Based on these results, we strongly recommend vitamin A supplementation for children aged under 5 in areas at risk of vitamin A deficiency. Despite widespread efforts, vitamin A programmes do not reach all children who could benefit.[15] Universal distribution could be achieved in several ways. Vitamin A supplementation can be provided when children receive other services like vaccinations,[102] and it can be provided on a large scale. Child health days or other strategies might be used to increase awareness,[103] and vitamin A uptake could be increased through national food programmes[104] or through delivery by community health workers.[105]

Implications for future research

The effectiveness of vitamin A supplementation is so well established that further placebo controlled studies are not required. Nevertheless, this review does not identify the most effective dose or frequency of delivery. Large doses in the included studies were effective. Smaller, more frequent doses might produce larger reductions in mortality; more complex and burdensome programmes, however, could result in lower coverage. We suggest that policymakers consider including trials of dose and frequency in vitamin A distribution programmes. Other studies might investigate different delivery channels, including food supplementation, horticultural innovations, improved access to food, or psychosocial programmes to increase uptake of foods rich in vitamin A.

Conclusions

Our review reaffirms compelling evidence that vitamin A supplements can prevent death and illness in children aged 6 months to 5 years. Supplements are inexpensive and have few side effects. Further trials are needed to determine the most effective dose and frequency of supplementation, but placebo controlled trials would be unethical. Policymakers should continue working to provide supplements for all children at risk of deficiency, particularly those in low and middle income countries.

We are grateful to the Cochrane Collaboration for their assistance in preparing this review. We particularly thank the Cochrane Developmental Psychosocial and Learning Problems Group, including Jo Abbott, Chris Champion, and Laura MacDonald. Margaret Anderson developed the search strategy and Geraldine Macdonald edited the review. We thank the Cochrane Editorial Unit, particularly Toby Lasserson, Rachel Murphy, and Karla Soares-Weiser for extracting data; we thank David Tovey and Harriet MacLehose for advice and for helping to manage the project. We are grateful to Toby Lasserson for the table summarising of findings. Henry Ebron from DistillerSR provided assistance managing the data. We thank Julian Higgins and the Cochrane Methods Group for statistical advice and assistance. Anonymous peer reviewers offered helpful feedback on the protocol and the review, for which we are grateful.

Contributors: All authors contributed to the planning, conduct, and reporting of this work, and to writing the abstract; specifically, the background (AI, EM-W), methods (EM-W, AI, KH), literature search (KH, AI, MYY), data extraction (EM-W, AI, KH, MYY), tables (AI, EM-W, MYY), data analysis (EM-W, KH), results (EM-W, KH), discussion (EM-W, AI, KH), and overall supervision (ZAB). In addition to the authors Margaret Anderson developed the search strategy. Toby Lasserson, Rachel Murphy, and Karla Soares-Weiser extracted data. Toby Lasserson made the summary of findings table. Julian Higgins provided statistical advice and calculated intracluster correlation coefficient values. ZAB is guarantor.

Funding: The preparation of this review was funded by the Department of Nutrition for Health and Development, WHO, Switzerland. EMW and KH were supported by the University of Oxford's department of social policy and intervention and the centre for evidence-based intervention. KH received funding from a Marshall scholarship. AI, MYY, and ZAB were supported by Aga Khan University, Karachi, Pakistan.

Competing interests: All authors have completed the ICMJE uniform disclosure form at www.icmje.org/coi_disclosure.pdf (available on request from the corresponding author) and declare: no support from any organisation for the submitted work; no financial relationships with any organisations that might have an interest in the submitted work in the previous three years; no other relationships or activities that could appear to have influenced the submitted work.

Ethical approval: Not required.

Data sharing: Detailed tables and effects for each study are available from our Cochrane Review (www.cochrane.org).

What is already known on this topic

Vitamin A is an essential nutrient; it must be obtained through diet

In low and middle income countries, many people (especially children) do not eat enough vitamin A

Vitamin A deficiency is related to vision problems and increased susceptibility to infectious disease and death

WHO recommends vitamin A supplements for children, pregnant women, and breastfeeding mothers

What this study adds

There have been 43 trials of vitamin A for children aged 6 months to 5 years old, including about 215 633 children

In low and middle income countries, vitamin A supplementation is associated with a 24% reduction in mortality

Vitamin A supplementation might reduce mortality by preventing measles and diarrhoea; it also prevents blindness

The evidence for vitamin A is compelling and clear; further trials comparing vitamin A with placebo would be unethical

Retinoids inhibit measles virus in vitro via nuclear retinoid receptor signaling pathways.

Trottier C[1], Chabot S, Mann KK, Colombo M, Chatterjee A, Miller WH Jr, Ward BJ.

Author information

Abstract

Measles virus (MV) infects 30 million children every year, resulting in more than half a million deaths. Vitamin A (retinol) treatment of acute measles can reduce measles-associated mortality by 50-80%. We sought to determine whether or not retinoids can act directly to limit MV output from infected cells. Physiologic concentrations of retinol were found to inhibit MV output in PBMC and a range of cell lines of epithelial and endothelial origin (40-50%). Near complete inhibition of viral output was achieved in some cells/lines treated with all-trans retinoic acid (ATRA) and 9-cis RA (9cRA). Important attenuation of the anti-MV effect of retinoids in R4 cells, a subclone of a retinoid-responsive cell line (NB4) deficient in RAR signaling, demonstrates that this effect is mediated at least in part by nuclear retinoid receptor signaling pathways. Inhibition of MV replication could not be fully explained as a result of retinoid effects on cell differentiation, proliferation or viability, particularly at low retinoid concentrations (1-10nM). These data provide the first evidence that retinoids can directly inhibit MV in vitro, and raise the possibility that retinoids may have similar actions in vivo.

Retinoids inhibit measles virus through a type I IFN-dependent bystander effect.

Trottier C[1], Colombo M, Mann KK, Miller WH Jr, Ward BJ.

Author information

1 Department of Infectious Diseases, McGill University Health Center Research Institute, McGill University, Montreal, Quebec, Canada.

Abstract

Measles-associated mortality can be decreased in response to treatment with vitamin A. Our goal was to understand the mechanism by which vitamin A and other retinoids reduce measles virus (MeV) replication in vitro. MeV is known to inhibit type I interferon (IFN) signaling, and retinoids are increasingly implicated in modulating innate immunity. Type I IFN blocking antibodies abrogated the inhibitory effects of all-trans retinoic acid (ATRA) on MeV replication (EC(50) of ATRA: 3.17 x 10(-8) M). IFN-stimulated genes (ISGs) are up-regulated by ATRA in MeV-infected U937 cell cultures starting at 12 h and reaching a plateau at 24 h postinfection when compared to either treatment or infection alone. We found that this increased gene expression occurs in uninfected cells by using a transwell system where the uninfected cells were separated from infected cells by a membrane with 0.02-muM pores. Uninfected bystander cells from the ATRA-treated transwells did not support substantial viral replication when subsequently infected with MeV. In the absence of ATRA, the cells from the uninfected chamber did not up-regulate ISG expression and were not protected from subsequent challenge with virus. These results demonstrate that retinoids inhibit MeV replication by up-regulating elements of the innate immune response in uninfected bystander cells, making them refractory to productive infection during subsequent rounds of viral replication.

Poliomyelitis

Epidemiology and Prevention of Vaccine-Preventable Diseases
The Pink Book: Course Textbook - 12th Edition (April 2011)

On this Page

Printer friendly version [511 KB, 14 pages]

The words polio (grey) and myelon (marrow, indicating the spinal cord) are derived from the Greek. It is the effect of poliomyelitis virus on the spinal cord that leads to the classic manifestation of paralysis.

Poliomyelitis

- First described by Michael Underwood in 1789
- First outbreak described in U.S. in 1843
- More than 21,000 paralytic cases reported in the U.S. in 1952
- Global eradication within next decade

Records from antiquity mention crippling diseases compatible with poliomyelitis. Michael Underwood first described a debility of the lower extremities in children that was recognizable as poliomyelitis in England in 1789. The first outbreaks in Europe were reported in the early 19th century, and outbreaks were first reported in the United States in 1843. For the next hundred years, epidemics of polio were reported from developed countries in the Northern Hemisphere each summer and fall. These epidemics became increasingly severe, and the average age of persons affected rose. The increasingly older age of persons with primary infection increased both the disease severity and number of deaths from polio. Polio reached a peak in the United States in 1952, with more than 21,000 paralytic cases. However, following introduction of effective vaccines, polio incidence declined rapidly. The last case of wild-virus polio acquired in the United States was in 1979, and global polio eradication may be achieved within the next decade.

Poliovirus

Poliovirus is a member of the enterovirus subgroup, family Picornaviridae. Enteroviruses are transient inhabitants of the gastrointestinal tract, and are stable at acid pH. Picornaviruses are small, ether-insensitive viruses with an RNA genome.

There are three poliovirus serotypes (P1, P2, and P3). There is minimal heterotypic immunity between the three serotypes. That is, immunity to one serotype does not produce significant immunity to the other serotypes.

Poliovirus

- Enterovirus (RNA)
- Three serotypes: 1, 2, 3
- Minimal heterotypic immunity between serotypes
- Rapidly inactivated by heat, formaldehyde, chlorine, ultraviolet light

The poliovirus is rapidly inactivated by heat, formaldehyde, chlorine, and ultraviolet light.

Pathogenesis

The virus enters through the mouth, and primary multiplication of the virus occurs at the site of implantation in the pharynx and gastrointestinal tract. The virus is usually present in the throat and in the stool before the onset of illness. One week after onset there is less virus in the throat, but virus continues to be excreted in the stool for several weeks. The virus invades local lymphoid tissue, enters the bloodstream, and then may infect cells of the central nervous system.

Poliomyelitis Pathogenesis

- Entry into mouth
- Replication in pharynx, GI tract, local lymphatics
- Hematologic spread to lymphatics and central nervous system

Replication of poliovirus in motor neurons of the anterior horn and brain stem results in cell destruction and causes the typical manifestations of poliomyelitis.

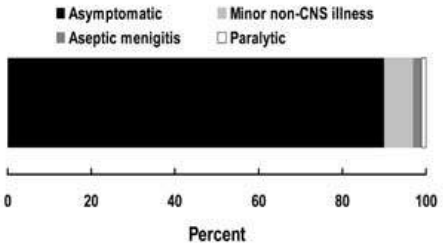
- Viral spread along nerve fibers
- Destruction of motor neurons

Clinical Features

The incubation period for poliomyelitis is commonly 6 to 20 days with a range of 3 to 35 days.

The response to poliovirus infection is highly variable and has been categorized on the basis of the severity of clinical presentation.

Outcomes of poliovirus infection



Up to 95% of all polio infections are inapparent or asymptomatic. Estimates of the ratio of inapparent to paralytic illness vary from 50:1 to 1,000:1 (usually 200:1). Infected persons without symptoms shed virus in the stool and are able to transmit the virus to others.

Approximately 4%–8% of polio infections consist of a minor, nonspecific illness without clinical or laboratory evidence of central nervous system invasion. This clinical presentation is known as abortive poliomyelitis, and is characterized by complete recovery in less than a week. Three syndromes observed with this form of poliovirus infection are upper respiratory tract infection (sore throat and fever), gastrointestinal disturbances (nausea, vomiting, abdominal pain, constipation or, rarely, diarrhea), and influenza-like illness. These syndromes are indistinguishable from other viral illnesses.

Nonparalytic aseptic meningitis (symptoms of stiffness of the neck, back, and/or legs), usually following several days after a prodrome similar to that of minor illness, occurs in 1%–2% of polio infections. Increased or abnormal sensations can also occur. Typically these symptoms will last from 2 to 10 days, followed by complete recovery.

Fewer than 1% of all polio infections result in flaccid paralysis. Paralytic symptoms generally begin 1 to 10 days after prodromal symptoms and progress for 2 to 3 days. Generally, no further paralysis occurs after the temperature returns to normal. The prodrome may be biphasic, especially in children, with initial minor symptoms separated by a 1- to 7-day period from more major symptoms. Additional prodromal signs and symptoms can include a loss of superficial reflexes, initially increased deep tendon reflexes and severe muscle aches and spasms in the limbs or back. The illness progresses to flaccid paralysis with diminished deep tendon reflexes, reaches a plateau without change for days to weeks, and is usually asymmetrical. Strength then begins to return. Patients do not experience sensory losses or changes in cognition.

Many persons with paralytic poliomyelitis recover completely and, in most, muscle function returns to some degree. Weakness or paralysis still present 12 months after onset is usually permanent.

Paralytic polio is classified into three types, depending on the level of involvement. Spinal polio is most common, and during 1969–1979, accounted for 79% of paralytic cases. It is characterized by asymmetric paralysis that most often involves the legs. Bulbar polio leads to weakness of muscles innervated by cranial nerves and accounted for 2% of cases during this period. Bulbospinal polio, a combination of bulbar and spinal paralysis, accounted for 19% of cases.

The death-to-case ratio for paralytic polio is generally 2%–5% among children and up to 15%–30% for adults (depending on age). It increases to 25%–75% with bulbar involvement.

*Less than 1% of all polio infections result in "paralytic polio". Of those cases, 2–5% result in death among children.

Laboratory Diagnosis

Viral Isolation

Poliovirus may be recovered from the stool or pharynx of a person with poliomyelitis. Isolation of virus from the cerebrospinal fluid (CSF) is diagnostic, but is rarely accomplished.

If poliovirus is isolated from a person with acute flaccid paralysis, it must be tested further, using oligonucleotide mapping (fingerprinting) or genomic sequencing, to deter-mine if the virus is “wild type” (that is, the virus that causes polio disease) or vaccine type (virus that could derive from a vaccine strain).

Serology

Neutralizing antibodies appear early and may be at high levels by the time the patient is hospitalized; therefore, a fourfold rise in antibody titer may not be demonstrated.

Cerebrospinal Fluid

In poliovirus infection, the CSF usually contains an increased number of white blood cells (10–200 cells/mm3, primarily lymphocytes) and a mildly elevated protein (40–50 mg/100 mL).

Epidemiology

Occurrence

At one time poliovirus infection occurred throughout the world. Transmission of wild poliovirus was interrupted in the United States in 1979, or possibly earlier. A polio eradication program conducted by the Pan American Health Organization led to elimination of polio in the Western Hemisphere in 1991. The Global Polio Eradication Program has dramatically reduced

poliovirus transmission throughout the world. In 2009, only 1,579 confirmed cases of polio were reported globally and polio was endemic in four countries.

Reservoir

Humans are the only known reservoir of poliovirus, which is transmitted most frequently by persons with inapparent infections. There is no asymptomatic carrier state except in immune deficient persons.

Transmission

Person-to-person spread of poliovirus via the fecal-oral route is the most important route of transmission, although the oral-oral route may account for some cases.

Temporal Pattern

Poliovirus infection typically peaks in the summer months in temperate climates. There is no seasonal pattern in tropical climates.

Communicability

Poliovirus is highly infectious, with seroconversion rates among susceptible household contacts of children nearly 100%, and greater than 90% among susceptible household contacts of adults. Persons infected with poliovirus are most infectious from 7 to 10 days before and after the onset of symptoms, but poliovirus may be present in the stool from 3 to 6 weeks.

Poliovirus Epidemiology

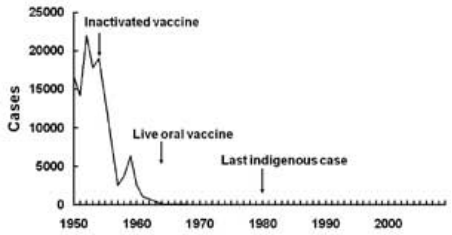
- Reservoir - Human
- Transmission - Fecal-oral
  Oral-oral possible
- Communicability - 7-10 days before onset
  Virus present in stool 3 to 6 weeks

Secular Trends in the United States

Before the 18th century, polioviruses probably circulated widely. Initial infections with at least one type probably occurred in early infancy, when transplacentally acquired maternal antibodies were high. Exposure throughout life probably provided continual boosting of immunity, and paralytic infections were probably rare. (This view has been recently challenged based on data from lameness studies in developing countries).

In the immediate prevaccine era, improved sanitation allowed less frequent exposure and increased the age of primary infection. Boosting of immunity from natural exposure became more infrequent and the number of susceptible persons accumulated, ultimately resulting in the occurrence of epidemics, with 13,000 to 20,000 para-lytic cases reported annually.

Poliomyelitis - United States, 1950-2009



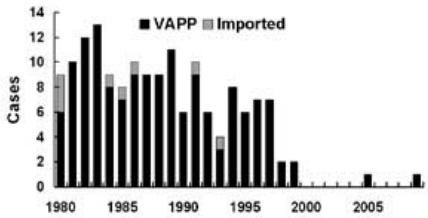
*See article "The Truth About the Polio Vaccines" under Incentives, Marketing, and Misconduct.

In the early vaccine era, the incidence dramatically decreased after the introduction of inactivated polio vaccine (IPV) in 1955. The decline continued following oral polio vaccine (OPV) introduction in 1961. In 1960, a total of 2,525 paralytic cases were reported, compared with 61 in 1965.

The last cases of paralytic poliomyelitis caused by endemic transmission of wild virus in the United States were in 1979, when an outbreak occurred among the Amish in several Midwest states. The virus was imported from the Netherlands.

From 1980 through 1999, a total of 152 confirmed cases of paralytic poliomyelitis were reported, an average of 8 cases per year. Six cases were acquired outside the United States and imported. The last imported case was reported in 1993. Two cases were classified as indeterminant (no poliovirus isolated from samples obtained from the patients, and patients had no history of recent vaccination or direct contact with a vaccine recipient). The remaining 144 (95%) cases were vaccine-associated paralytic polio (VAPP) caused by live oral polio vaccine.

Poliomyelitis - United States, 1980-2009



In order to eliminate VAPP from the United States, ACIP recommended in 2000 that IPV be used exclusively in the United States. The last case of VAPP acquired in the United States was reported in 1999. In 2005, an unvaccinated U.S. resident was infected with polio vaccine virus in Costa Rica and subsequently developed VAPP. A second case of VAPP from vaccine-derived poliovirus was reported in 2009. Also in 2005, several asymptomatic infections with a vaccine-derived poliovirus were detected in unvaccinated children in Minnesota. The source of the vaccine virus has not been determined, but it appeared to have been circulating among humans for at least 2 years based on genetic changes in the virus. No VAPP has been reported from this virus.

Poliovirus Vaccines

Inactivated poliovirus vaccine (IPV) was licensed in 1955 and was used extensively from that time until the early 1960s. In 1961, type 1 and 2 monovalent oral poliovirus vaccine (MOPV) was licensed, and in 1962, type 3 MOPV was licensed. In 1963,

Poliovirus Vaccine

- 1955 - Inactivated vaccine
- 1961 - Types 1 and 2 monovalent OPV

trivalent OPV was licensed and largely replaced IPV use. Trivalent OPV was the vaccine of choice in the United States and most other countries of the world after its introduction in 1963. An enhanced-potency IPV was licensed in November 1987 and first became available in 1988. Use of OPV was discontinued in the United States in 2000.

- 1962 - Type 3 monovalent OPV
- 1963 - Trivalent OPV
- 1987 - Enhanced-potency IPV (IPV)

Characteristics

Inactivated poliovirus vaccine

Two enhanced forms of inactivated poliovirus vaccine are currently licensed in the U.S., but only one vaccine (IPOL, sanofi pasteur) is actually distributed. This vaccine contains all three serotypes of polio vaccine virus. The viruses are grown in a type of monkey kidney tissue culture (Vero cell line) and inactivated with formaldehyde. The vaccine contains 2-phenoxyethanol as a preservative, and trace amounts of neomycin, streptomycin, and polymyxin B. It is supplied in a single-dose prefilled syringe and should be administered by either subcutaneous or intramuscular injection.

Inactivated Polio Vaccine

- Contains 3 serotypes of vaccine virus
- Grown on monkey kidney (Vero) cells
- Inactivated with formaldehyde
- Contains 2-phenoxyethanol, neomycin, streptomycin, polymyxin B

Oral poliovirus vaccine

Trivalent OPV contains live attenuated strains of all three serotypes of poliovirus in a 10:1:3 ratio. The vaccine viruses are grown in monkey kidney tissue culture (Vero cell line). The vaccine is supplied as a single 0.5-mL dose in a plastic dispenser. The vaccine contains trace amounts of neomycin and streptomycin. OPV does not contain a preservative.

Oral Polio Vaccine

- Contains 3 serotypes of vaccine virus
- Grown on monkey kidney (Vero) cells
- Contains neomycin and streptomycin
- Shed in stool for up to 6 weeks following vaccination

Live attenuated polioviruses replicate in the intestinal mucosa and lymphoid cells and in lymph nodes that drain the intestine. Vaccine viruses are excreted in the stool of the vaccinated person for up to 6 weeks after a dose. Maximum viral shedding occurs in the first 1–2 weeks after vaccination, particularly after the first dose.

Vaccine viruses may spread from the recipient to contacts. Persons coming in contact with fecal material of a vaccinated person may be exposed and infected with vaccine virus.

Immunogenicity and Vaccine Efficacy

Inactivated poliovirus vaccine

IPV is highly effective in producing immunity to poliovirus and protection from paralytic poliomyelitis. Ninety percent or more of vaccine recipients develop protective antibody to all three poliovirus types after two doses, and at least 99% are immune following three doses. Protection against paralytic disease correlates with the presence of antibody.

Inactivated Polio Vaccine

- Highly effective in producing immunity to poliovirus
- 90% or more immune after 2 doses
- At least 99% immune after 3 doses
- Duration of immunity not known with certainty

IPV appears to produce less local gastrointestinal immunity than does OPV, so persons who receive IPV are more readily infected with wild poliovirus than OPV recipients.

The duration of immunity with IPV is not known with certainty, although it probably provides protection for many years after a complete series.

Oral poliovirus vaccine

OPV is highly effective in producing immunity to poliovirus. A single dose of OPV produces immunity to all three vaccine viruses in approximately 50% of recipients. Three doses produce immunity to all three poliovirus types in more than 95% of recipients. As with other live-virus vaccines, immunity from oral poliovirus vaccine is probably lifelong. OPV produces excellent intestinal immunity, which helps prevent infection with wild virus.

Oral Polio Vaccine

- Highly effective in producing immunity to poliovirus
- Approximately 50% immune after 1 dose
- More than 95% immune after 3 doses
- Immunity probably lifelong

Serologic studies have shown that seroconversion following three doses of either IPV or OPV is nearly 100% to all three vaccine viruses. However, seroconversion rates after three doses of a combination of IPV and OPV are lower, particularly to type 3 vaccine virus (as low as 85% in one study). A fourth dose (most studies used OPV as the fourth dose) usually produces seroconversion rates similar to three doses of either IPV or OPV.

Vaccination Schedule and Use

Trivalent OPV was the vaccine of choice in the United States (and most other countries of the world) since it was licensed in 1963. The nearly exclusive use of OPV led to elimination of wild-type poliovirus from the United States in less than 20 years. However, one case of VAPP occurred for every 2 to 3 million doses of OPV administered, which resulted in 8 to 10 cases of VAPP each year in the United States (see Adverse Reactions section for more details on VAPP). From 1980 through 1999, VAPP accounted for 95% of all cases of paralytic poliomyelitis reported in the United States.

Polio Vaccination Recommendations, 1996-1999

- Increased use of IPV (sequential IPV-OPV schedule) recommended in 1996
- Intended to reduce the risk of vaccine-associated paralytic polio

In 1996, ACIP recommended an increase in use of IPV through a sequential schedule of IPV followed by OPV. This recommendation was intended to reduce the occurrence of vaccine-associated paralytic polio. The sequential schedule was expected to eliminate VAPP among vaccine recipients by producing humoral immunity to polio vaccine viruses with inactivated polio vaccine prior to exposure to live vaccine virus. Since OPV was still used for the third and fourth doses of the polio vaccination schedule, a risk of VAPP would continue to exist among contacts of vaccinees, who were exposed to live vaccine virus in the stool of vaccine recipients.

The sequential IPV–OPV polio vaccination schedule was widely accepted by both providers and parents. Fewer cases of VAPP were reported in 1998 and 1999, suggesting an impact of the increased use of IPV. However, only the complete discontinuation of use of OPV would lead to complete elimination of VAPP. To further the goal of complete elimination of paralytic polio in the United States, ACIP recommended in July 1999 that inactivated polio vaccine be used exclusively in the United States beginning in 2000. OPV is no longer routinely available in the United States. Exclusive use of IPV eliminated the shedding of live vaccine virus, and eliminated any indigenous VAPP.

A primary series of IPV consists of three doses. In infancy, these primary doses are integrated with the administration of other routinely administered vaccines. The first dose may be given as early as 6 weeks of age but is usually given at 2 months of age, with a second dose at 4 months of age. The third dose should be given at 6–18 months of age. The recommended interval between the primary series doses is 2 months. However, if accelerated protection is needed, the minimum interval between each of the first 3 doses of IPV is 4 weeks.

The final dose in the IPV series should be administered at 4 years of age or older. A dose of IPV on or after age 4 years is recommended regardless of the number of previous doses. The minimum interval from the next-to-last to final dose is 6 months.

When DTaP-IPV/Hib (Pentacel) is used to provide 4 doses at ages 2, 4, 6, and 15-18 months, an additional booster dose of age-appropriate IPV-containing vaccine (IPV or DTaP-IPV [Kinrix]) should be administered at age 4-6 years. This will result in a 5-dose IPV vaccine series, which is considered acceptable by ACIP. DTaP-IPV/Hib is not indicated for the booster dose at 4-6 years of age. ACIP recommends that the minimum interval from dose 4 to dose 5 should be at least 6 months to provide an optimum booster response.

Shorter intervals between doses and beginning the series at a younger age may lead to lower seroconversion rates. Consequently, ACIP recommends the use of the minimum age (6 weeks) and minimum intervals between doses in the first 6 months of life only if the vaccine recipient is at risk for imminent exposure to circulating poliovirus (e.g., during an outbreak or because of travel to a polio-endemic region).

Only IPV is available for routine polio vaccination of children in the United States. A polio vaccination schedule begun with OPV should be completed with IPV. If a child receives both types of vaccine, four doses of any combination of IPV or OPV by 4–6 years of age is considered a complete poliovirus vaccination series. A minimum interval of 4 weeks should separate all doses of the series.

There are three combination vaccines that contain inactivated polio vaccine. Pediarix is produced by GlaxoSmithKline and contains DTaP, hepatitis B and IPV vaccines. Pediarix is licensed for the first 3 doses of the DTaP series among children 6 weeks through 6 years of age. Kinrix is also produced by GSK and contains DTaP and IPV. Kinrix is licensed only for the fifth dose of DTaP and fourth dose of IPV among children 4 through 6 years of age. Pentacel is produced by sanofi pasteur and contains DTaP, Hib and IPV. It is licensed for the first four doses of the component vaccines among children 6 weeks through 4 years of age. Pentacel is not licensed for children 5 years or older. Additional information about these combination vaccines is in the Pertussis chapter of this book.

(VAPP)
- Continued risk of VAPP for contacts of OPV recipients

Polio Vaccination Schedule

Age	Vaccine	Minimum Interval
2 months	IPV	--
4 months	IPV	4 weeks
6-18 months	IPV	4 weeks
4-6 years	IPV	6 months

Polio Vaccination Recommendations

- Exclusive use of IPV recommended in 2000
- OPV no longer routinely available in the United States
- Indigenous VAPP eliminated

Schedules That Include Both IPV and OPV

- Only IPV is available in the United States
- Schedule begun with OPV should be completed with IPV
- Any combination of 4 doses of IPV and OPV by 4-6 years of age constitutes a complete series

Combination Vaccines That Contain IPV

- Pediarix
  - DTaP, Hepatitis B and IPV
- Kinrix
  - DTaP and IPV
- Pentacel
  - .DTaP, Hib and IPV

Polio Vaccination of Adults

- Routine vaccination of U.S. residents 18 years of age and older not necessary or recommended
- May consider vaccination of travelers to polio-endemic countries and selected laboratory workers

Polio Vaccination of Adults

Routine vaccination of adults (18 years of age and older) who reside in the United States is not necessary or recommended because most adults are already immune and have a very small risk of exposure to wild poliovirus in the United States.

Some adults, however, are at increased risk of infection with poliovirus. These include travelers to areas where poliomyelitis is endemic or epidemic (currently limited to South Asia, the eastern Mediterranean, and Africa), laboratory workers handling specimens that may contain polioviruses, and healthcare personnel in close contact with patients who may be excreting wild

polioviruses. In addition, members of specific population groups with a current disease caused by wild polioviruses (e.g., during an outbreak) are also at increased risk.

Recommendations for poliovirus vaccination of adults in the above categories depend upon the previous vaccination history and the time available before protection is required.

- For unvaccinated adults (including adults without a written record of prior polio vaccination) at increased risk of exposure to poliomyelitis, primary immunization with IPV is recommended. The recommended schedule is two doses separated by 1 to 2 months, and a third dose given 6 to 12 months after the second dose. The minimum interval between the second and the third doses is 6 months.

Polio Vaccination of Unvaccinated Adults

- Use standard IPV schedule if possible (0, 1-2 months, 6-12 months)
- May separate first and second doses by 4 weeks if accelerated schedule needed
- The minimum interval between the second and third doses is 6 months

In some circumstances time will not allow completion of this schedule. If 8 weeks or more are available before protection is needed, three doses of IPV should be given at least 4 weeks apart. If 4 to 8 weeks are available before protection is needed, two doses of IPV should be given at least 4 weeks apart. If less than 4 weeks are available before protection is needed, a single dose of IPV is recommended. In all instances, the remaining doses of vaccine should be given later, at the recommended intervals, if the person remains at increased risk.

- Adults who have previously completed a primary series of 3 or more doses and who are at increased risk of exposure to poliomyelitis should be given one dose of IPV. The need for further supplementary doses has not been established. Only one supplemental dose of polio vaccine is recommended for adults who have received a complete series (i.e., it is not necessary to administer additional doses for subsequent travel to a polio endemic country).
- Adults who have previously received less than a full primary course of OPV or IPV and who are at increased risk of exposure to poliomyelitis should be given the remaining doses of IPV, regardless of the interval since the last dose and type of vaccine previously received. It is not necessary to restart the series of either vaccine if the schedule has been interrupted.

Polio Vaccination of Previously Vaccinated Adults

- Previously complete series
  - administer one dose of IPV
- Incomplete series
  - administer remaining doses in series
  - no need to restart series

Contraindications and Precautions to Vaccination

Severe allergic reaction (anaphylaxis) to a vaccine component, or following a prior dose of vaccine, is a contraindication to further doses of that vaccine. Since IPV contains trace amounts of streptomycin, neomycin, and polymyxin B, there is a possibility of allergic reactions in persons sensitive to these antibiotics. Persons with allergies that are not anaphylactic, such as skin contact sensitivity, may be vaccinated.

Moderate or severe acute illness is a precaution for IPV.

Polio Vaccine Contraindications and Precautions

- Severe allergic reaction to a vaccine component or following a prior dose of vaccine
- Moderate or severe acute illness

Breastfeeding does not interfere with successful immunization against poliomyelitis with IPV. IPV may be administered to a child with diarrhea. Minor upper respiratory illnesses with or without fever, mild to moderate local reactions to a prior dose of vaccine, current antimicrobial therapy, and the convalescent phase of an acute illness are not contraindication for vaccination with IPV.

Contraindications to combination vaccines that contain IPV are the same as the contraindications to the individual components (e.g., DTaP, hepatitis B).

Adverse Reactions Following Vaccination

Minor local reactions (pain, redness) may occur following IPV. No serious adverse reactions to IPV have been documented. Because IPV contains trace amounts of streptomycin, polymyxin B, and neomycin, allergic reactions may occur in persons sensitive to these antibiotics.

Polio Vaccines Adverse Reactions

- Rare local reactions (IPV)
- No serious reactions to IPV have been documented
- Paralytic poliomyelitis (OPV)

Vaccine-Associated Paralytic Poliomyelitis

Vaccine-associated paralytic polio is a rare adverse reaction following live oral poliovirus vaccine. Inactivated poliovirus vaccine does not contain live virus, so it cannot cause VAPP. The mechanism of VAPP is believed to be a mutation, or reversion, of the vaccine virus to a more neurotropic form. These mutated viruses are called revertants. Reversion is believed to occur in almost all vaccine recipients, but it only rarely results in paralytic disease. The paralysis that results is identical to that caused by wild virus, and may be permanent.

VAPP is more likely to occur in persons 18 years of age and older than in children, and is much more likely to occur in immunodeficient children than in those who are immunocompetent. Compared with immunocompetent children, the risk of VAPP is almost 7,000 times higher for persons with certain types of immunodeficiencies, particularly B-lymphocyte disorders (e.g., agammaglobulinemia and hypogammaglobulinemia), which reduce the synthesis of immune globulins. There is no procedure available for identifying

Vaccine-Associated Paralytic Polio

- Increased risk in persons 18 years and older
- Increased risk in persons with immunodeficiency

persons at risk of paralytic disease, except excluding older persons and screening for immunodeficiency.

- No procedure available for identifying persons at risk of paralytic disease
- 5-10 cases per year with exclusive use of OPV
- Most cases in healthy children and their household contacts

From 1980 through 1998, 152 cases of paralytic polio were reported in the United States; 144 (95%) of these cases were VAPP, and the remaining eight were in persons who acquired documented or presumed wild-virus polio outside the United States. Of the 144 VAPP cases, 59 (41%) occurred in healthy vaccine recipients (average age 3 months). Forty-four (31%) occurred in healthy contacts of vaccine recipients (average age 26 years), and 7 (5%) were community acquired (i.e., vaccine virus was recovered but there was no known contact with a vaccine recipient). Thirty-four (24%) of VAPP cases occurred in persons with immunologic abnormalities (27 in vaccine recipients and 7 in contacts of vaccine recipients). None of the vaccine recipients were known to be immunologically abnormal prior to vaccination.

Vaccine-Associated Paralytic Polio (VAPP) 1980-1998

- Healthy recipients of OPV - 41%
- Healthy contacts of OPV recipients - 31%
- Community acquired - 5%
- Immunodeficient - 24%

The risk of VAPP is not equal for all OPV doses in the vaccination series. The risk of VAPP is 7 to 21 times higher for the first dose than for any other dose in the OPV series. From 1980 through 1994, 303 million doses of OPV were distributed and 125 cases of VAPP were reported, for an overall risk of VAPP of one case per 2.4 million doses. Forty-nine paralytic cases were reported among immunocompetent recipients of OPV during this period. The overall risk to these recipients was one VAPP case per 6.2 million OPV doses. However, 40 (82%) of these 49 cases occurred following receipt of the first dose, making the risk of VAPP one case per 1.4 million first doses. The risk for all other doses was one per 27.2 million doses. The reason for this difference by dose is not known with certainty, but it is probably because the vaccine virus is able to replicate longer in a completely nonimmune infant. This prolonged replication increases the chance of the emergence of a revertant virus that may cause paralysis. The situation is similar for contacts. A nonimmune child may shed virus longer, increasing the chance of exposure of a contact.

The last case of VAPP acquired in the United States was reported in 1999. As noted previously, a U.S. resident with VAPP was reported in 2005, but the vaccine virus infection was acquired in Costa Rica.

Vaccine Storage and Handling

IPV may be shipped without refrigeration provided it is delivered within 4 days. It should be maintained at 35°–46°F (2°–8°C). The vaccine should be clear and colorless. Any vaccine showing particulate matter, turbidity, or change in color should be discarded.

Outbreak Investigation and Control

Collect preliminary clinical and epidemiologic information (including vaccine history and contact with OPV vaccines) on any suspected case of paralytic polio. Notify CDC, (404-639-8255) after appropriate local and state health authorities have been notified. Intensify field investigation to verify information and collect appropriate specimens for viral isolation and serology.

Polio Eradication

- Last case in United States in 1970
- Western Hemisphere certified polio free in 1994
- Last isolate of type 2 poliovirus in India in October 1999
- Global eradication goal

A single case of paralytic poliomyelitis demands immediate attention. If the evidence indicates vaccine-associated disease, no outbreak control program is needed. If, however, evidence indicates wild virus (for example, two cases in a community), all unvaccinated persons in the epidemic area who are 6 weeks of age and older and whose vaccine histories are uncertain should be vaccinated.

Polio Eradication

Following the widespread use of poliovirus vaccine in the mid-1950s, the incidence of poliomyelitis declined rapidly in many industrialized countries. In the United States, the number of cases of paralytic poliomyelitis reported annually declined from more than 20,000 cases in 1952 to fewer than 100 cases in the mid-1960s. The last documented indigenous transmission of wild poliovirus in the United States was in 1979.

Wild Poliovirus 1988

In 1985, the member countries of the Pan American Health Organization adopted the goal of eliminating poliomyelitis from the Western Hemisphere by 1990. The strategy to achieve this goal included increasing vaccination coverage; enhancing surveillance for suspected cases (i.e., surveillance for acute flaccid paralysis); and using supplemental immunization strategies such as national immunization days, house-to-house vaccination, and containment activities. Since 1991, when the last wild-virus–associated indigenous case was reported from Peru, no additional cases of poliomyelitis have been confirmed despite intensive surveillance. In September 1994, an international commission certified the Western Hemisphere to be free of indigenous wild poliovirus. The commission based its judgment on detailed reports from national certification commissions that had been convened in every country in the region.

In 1988, the World Health Assembly (the governing body of the World Health Organization) adopted the goal of global eradication of poliovirus by the year 2000. Although this goal was not achieved, substantial progress has been made. One type of poliovirus appears to have already been eradicated. In 1988, an estimated 350,000 cases of paralytic polio occurred, and the disease was endemic in more than 125 countries. By 2006, fewer than 2,000 cases were reported globally—a reduction of more than 99% from 1988—and polio remained endemic in only four countries. In addition, one type of poliovirus appears to have already been eradicated. The last isolation of type 2 virus was in India in October 1999.

Wild Poliovirus 2008

The polio eradication initiative is led by a coalition of international organizations that includes WHO, the United Nations Children's Fund (UNICEF), CDC, and Rotary International. Other bilateral and multilateral organizations also support the initiative. Rotary International has contributed more than $600 million to support the eradication initiative. Current information on the status of the global polio eradication initiative is available on the World Health Organization website .

Postpolio Syndrome

After an interval of 30–40 years, 25%–40% of persons who contracted paralytic poliomyelitis in childhood experience new muscle pain and exacerbation of existing weakness, or develop new weakness or paralysis. This disease entity is referred to as postpolio syndrome. Factors that increase the risk of postpolio syndrome include increasing length of time since acute poliovirus infection, presence of permanent residual impairment after recovery from the acute illness, and female sex. The pathogenesis of postpolio syndrome is thought to involve the failure of oversized motor units created during the recovery process of paralytic poliomyelitis. Postpolio syndrome is not an infectious process, and persons experiencing the syndrome do not shed poliovirus.

A positive association found between autism prevalence and childhood vaccination uptake across the U.S. population.

Delong G[1].

Author information

Abstract

The reason for the rapid rise of autism in the United States that began in the 1990s is a mystery. Although individuals probably have a genetic predisposition to develop autism, researchers suspect that one or more environmental triggers are also needed. One of those triggers might be the battery of vaccinations that young children receive. Using regression analysis and controlling for family income and ethnicity, the relationship between the proportion of children who received the recommended vaccines by age 2 years and the prevalence of autism (AUT) or speech or language impairment (SLI) in each U.S. state from 2001 and 2007 was determined. A positive and statistically significant relationship was found: The higher the proportion of children receiving recommended vaccinations, the higher was the prevalence of AUT or SLI. A 1% increase in vaccination was associated with an additional 680 children having AUT or SLI. Neither parental behavior nor access to care affected the results, since vaccination proportions were not significantly related (statistically) to any other disability or to the number of pediatricians in a U.S. state. The results suggest that although mercury has been removed from many vaccines, other culprits may link vaccines to autism. Further study into the relationship between vaccines and autism is warranted.

Do aluminum vaccine adjuvants contribute to the rising prevalence of autism?

Tomljenovic L[1], Shaw CA.

Author information

Abstract

Autism spectrum disorders (ASD) are serious multisystem developmental disorders and an urgent global public health concern. Dysfunctional immunity and impaired brain function are core deficits in ASD. Aluminum (Al), the most commonly used vaccine adjuvant, is a demonstrated neurotoxin and a strong immune stimulator. Hence, adjuvant Al has the potential to induce neuroimmune disorders. When assessing adjuvant toxicity in children, two key points ought to be considered: (i) children should not be viewed as "small adults" as their unique physiology makes them much more vulnerable to toxic insults; and (ii) if exposure to Al from only few vaccines can lead to cognitive impairment and autoimmunity in adults, is it unreasonable to question whether the current pediatric schedules, often containing 18 Al adjuvanted vaccines, are safe for children? By applying Hill's criteria for establishing causality between exposure and outcome we investigated whether exposure to Al from vaccines could be contributing to the rise in ASD prevalence in the Western world. Our results show that: (i) children from countries with the highest ASD prevalence appear to have the highest exposure to Al from vaccines; (ii) the increase in exposure to Al adjuvants significantly correlates with the increase in ASD prevalence in the United States observed over the last two decades (Pearson r=0.92, p<0.0001); and (iii) a significant correlation exists between the amounts of Al administered to preschool children and the current prevalence of ASD in seven Western countries, particularly at 3-4 months of age (Pearson r=0.89-0.94, p=0.0018-0.0248). The application of the Hill's criteria to these data indicates that the correlation between Al in vaccines and ASD may be causal. Because children represent a fraction of the population most at risk for complications following exposure to Al, a more rigorous evaluation of Al adjuvant safety seems warranted.

A possible central mechanism in autism spectrum disorders, part 1.

Blaylock RL[1].

Author information

Abstract

The autism spectrum disorders (ASD) are a group of related neurodevelopmental disorders that have been increasing in incidence since the 1980s. Despite a considerable amount of data being collected from cases, a central mechanism has not been offered. A careful review of ASD cases discloses a number of events that adhere to an immunoexcitotoxic mechanism. This mechanism explains the link between excessive vaccination, use of aluminum and ethylmercury as vaccine adjuvants, food allergies, gut dysbiosis, and abnormal formation of the developing brain. It has now been shown that chronic microglial activation is present in autistic brains from age 5 years to age 44 years. A considerable amount of evidence, both experimental and clinical, indicates that repeated microglial activation can initiate priming of the microglia and that subsequent stimulation can produce an exaggerated microglial response that can be prolonged. It is also known that one phenotypic form of microglia activation can result in an outpouring of neurotoxic levels of the excitotoxins, glutamate and quinolinic acid. Studies have shown that careful control of brain glutamate levels is essential to brain pathway development and that excesses can result in arrest of neural migration, as well as dendritic and synaptic loss. It has also been shown that certain cytokines, such as TNF-alpha, can, via its receptor, interact with glutamate receptors to enhance the neurotoxic reaction. To describe this interaction I have coined the term immunoexcitotoxicity, which is described in this article.

Hepatitis B vaccination of male neonates and autism diagnosis, NHIS 1997-2002.

Gallagher CM[1], Goodman MS.

Author information

Abstract

Universal hepatitis B vaccination was recommended for U.S. newborns in 1991; however, safety findings are mixed. The association between hepatitis B vaccination of male neonates and parental report of autism diagnosis was determined. This cross-sectional study used weighted probability samples obtained from National Health Interview Survey 1997-2002 data sets. Vaccination status was determined from the vaccination record. Logistic regression was used to estimate the odds for autism diagnosis associated with neonatal hepatitis B vaccination among boys age 3-17 years, born before 1999, adjusted for race, maternal education, and two-parent household. Boys vaccinated as neonates had threefold greater odds for autism diagnosis compared to boys never vaccinated or vaccinated after the first month of life. Non-Hispanic white boys were 64% less likely to have autism diagnosis relative to nonwhite boys. Findings suggest that U.S. male neonates vaccinated with the hepatitis B vaccine prior to 1999 (from vaccination record) had a threefold higher risk for parental report of autism diagnosis compared to boys not vaccinated as neonates during that same time period. Nonwhite boys bore a greater risk.

Abstract

Autism spectrum disorder is a neurodevelopmental disorder of unknown aetiology. It is suggested to involve both genetic susceptibility and environmental factors including in the latter environmental toxins. Human exposure to the environmental toxin aluminium has been linked, if tentatively, to autism spectrum disorder. Herein we have used transversely heated graphite furnace atomic absorption spectrometry to measure, for the first time, the aluminium content of brain tissue from donors with a diagnosis of autism. We have also used an aluminium-selective fluor to identify aluminium in brain tissue using fluorescence microscopy. The aluminium content of brain tissue in autism was consistently high. The mean (standard deviation) aluminium content across all 5 individuals for each lobe were 3.82(5.42), 2.30(2.00), 2.79(4.05) and 3.82(5.17) μg/g dry wt. for the occipital, frontal, temporal and parietal lobes respectively. These are some of the highest values for aluminium in human brain tissue yet recorded and one has to question why, for example, the aluminium content of the occipital lobe of a 15 year old boy would be 8.74 (11.59) μg/g dry wt.? Aluminium-selective fluorescence microscopy was used to identify aluminium in brain tissue in 10 donors. While aluminium was imaged associated with neurones it appeared to be present intracellularly in microglia-like cells and other inflammatory non-neuronal cells in the meninges, vasculature, grey and white matter. The pre-eminence of intracellular aluminium associated with non-neuronal cells was a standout observation in autism brain tissue and may offer clues as to both the origin of the brain aluminium as well as a putative role in autism spectrum disorder.

1. Introduction

Autism spectrum disorder (ASD) is a group of neurodevelopmental conditions of unknown cause. It is highly likely that both genetic [1] and environmental [2] factors are associated with the onset and progress of ASD while the mechanisms underlying its aetiology are expected to be multifactorial [3], [4], [5], [6]. Human exposure to aluminium has been implicated in ASD with conclusions being equivocal [7], [8], [9], [10]. To-date the majority of studies have used hair as their indicator of human exposure to aluminium while aluminium in blood and urine have also been used to a much more limited extent. Paediatric vaccines that include an aluminium adjuvant are an indirect measure of infant exposure to aluminium and their burgeoning use has been directly correlated with increasing prevalence of ASD [11]. Animal models of ASD continue to support a connection with aluminium and to aluminium adjuvants used in human vaccinations in particular [12]. Hitherto there are no previous reports of aluminium in brain tissue from donors who died with a diagnosis of ASD. We have measured aluminium in brain tissue in autism and identified the location of aluminium in these tissues.

2. Materials and methods

2.1. Measurement of aluminium in brain tissues

Ethical approval was obtained along with tissues from the Oxford Brain Bank (15/SC/0639). Samples of cortex of approximately 1 g frozen weight from temporal, frontal, parietal and occipital lobes and hippocampus (0.3 g only) were obtained from 5 individuals with ADI-R-confirmed (Autism Diagnostic Interview-Revised) ASD, 4 males and 1 female, aged 15–50 years old (Table 1).

Table 1. Aluminium content of occipital (O), frontal (F), temporal (T) and parietal (P) lobes and hippocampus (H) of brain tissue from 5 donors with a diagnosis of autism spectrum disorder.

The aluminium content of these tissues was measured by an established and fully validated method [13] that herein is described only briefly. Thawed tissues were cut using a stainless steel blade to give individual samples of ca 0.3 g (3 sample replicates for each lobe except for hippocampus where the tissue was used as supplied) wet weight and dried to a constant weight at 37 °C. Dried and weighed tissues were digested in a microwave (MARS Xpress CEM Microwave Technology Ltd.) in a mixture of 1 mL 15.8 M HNO_3 (Fisher Analytical Grade) and 1 mL 30% w/v H_2O_2 (BDH Aristar). Digests were clear with no fatty residues and, upon cooling, were made up to 5 mL volume using ultrapure water (cond.<0.067 μS/cm). Total aluminium was measured in each sample by transversely heated graphite furnace atomic absorption spectrometry (TH GFAAS) using matrix-matched standards and an established analytical programme alongside previously validated quality assurance data [13].

2.2. Fluorescence microscopy

All chemicals were from Sigma Aldrich (UK) unless otherwise stated. Where available frontal, parietal, occipital, temporal and hippocampal tissue from 10 donors (3 females and 7 males) with a diagnosis of ASD was supplied by the Oxford Brain Bank as three 5 μm thick serial paraffin-embedded brain tissue sections per lobe for each donor (Table S1). Tissue sections mounted on glass slides were placed in a slide rack and de-waxed and rehydrated via transfer through 250 mL of the following reagents: 3 min in Histo-Clear (National Diagnostics, US), 1 min in fresh Histo-Clear, 2 min in 100% v/v ethanol (HPLC grade) and 1 min in 95, 70, 50 & 30% v/v ethanol followed by rehydration in ultrapure water (cond.<0.067 μS/cm) for 35 s. Slides were agitated every 20 s in each solvent and blotted on tissue paper between transfers to minimise solvent carry-over. Rehydrated brain tissue sections were carefully outlined with a PAP pen for staining, in order to form a hydrophobic barrier around the periphery of tissue sections. In between staining, tissue sections were kept hydrated with ultrapure water and stored in moisture chambers, to prevent sections from drying out. Staining was staggered to allow for accurate incubation times of brain tissue sections. We have developed and optimised the fluor lumogallion as a selective stain for aluminium in cells [14] and human tissues [15]. Lumogallion (4-chloro-3-(2,4-dihydroxyphenylazo)-2-hydroxybenzene-1-sulphonic acid, TCI Europe N.V. Belgium) was prepared at ca 1 mM via dilution in a 50 mM PIPES (1,4-Piperazinediethanesulphonic acid) buffer, adjusted to pH 7.4 with NaOH. Lumogallion staining was performed via the addition of 200 μL of the staining solution to rehydrated brain tissue sections that were subsequently incubated at ambient temperature away from light for 45 min. Sections for autofluorescence analyses were incubated for 45 min in 200 μL 50 mM PIPES buffer only, pH 7.4. Following staining, glass slides containing tissue sections were washed six times with 200 μL aliquots of 50 mM PIPES buffer, pH 7.4, prior to rinsing for 30 s in ultrapure water. Serial sections numbered 1 and 2 for each lobe were incubated in 50 mM PIPES buffer, pH 7.4 or stained with 1 mM lumogallion in the same buffer, respectively, to ensure consistency across donor tissues.

All tissue sections were subsequently mounted under glass coverslips using the aqueous mounting medium, Fluoromount™. Slides were stored horizontally for 24 h at 4 °C away from light, prior to analysis via fluorescence microscopy.

Stained and mounted human brain tissue sections were analysed via the use of an Olympus BX50 fluorescence microscope, equipped with a vertical illuminator and BX-FLA reflected light fluorescence attachment (mercury source). Micrographs were obtained at X 400 magnification by use of a X 40 Plan-Fluorite objective (Olympus, UK). Lumogallion-reactive aluminium and related autofluorescence micrographs were obtained via use of a U-MNIB3 fluorescence filter cube (excitation: 470–495 nm, dichromatic mirror: 505 nm, longpass emission: 510 nm, Olympus, UK). Light exposure and transmission values were fixed across respective staining treatment conditions and images were obtained using the CellD software suite (Olympus, Soft Imaging Solutions, SiS, GmbH). Lumogallion-reactive regions identified through sequential screening of stained human brain tissue sections were additionally imaged on autofluorescence serial sections, to assess the contribution of the fluorophore. The subsequent merging of fluorescence and bright-field channels was achieved using Photoshop (Adobe Systems Inc. US). When determining intracellular staining the type of cells stained were estimated by their size and shape in the context of the brain area sampled and their surrounding cellular environment.

3. Results

3.1. Aluminium content of brain tissues

The aluminium content of all tissues ranged from 0.01 (the limit of quantitation) to 22.11 μg/g dry wt. (Table 1). The aluminium content for whole brains (n = 4 or 5 depending upon the availability of hippocampus tissue) ranged from 1.20 (1.06) μg/g dry wt. for the 44 year old female donor (A1) to 4.77 (4.79) μg/g dry wt. for a 33 year old male donor (A5). Previous measurements of brain aluminium, including our 60 brain study [13], have allowed us to define loose categories of brain aluminium content beginning with ≤1.00 μg/g dry wt. as pathologically benign (as opposed to 'normal'). Approximately 40% of tissues (24/59) had an aluminium content considered as pathologically-concerning (≥2.00 μg/g dry wt.) while approximately 67% of these tissues had an aluminium content considered as pathologically-significant (≥3.00 μg/g dry wt.). The brains of all 5 individuals had at least one tissue with a pathologically-significant content of aluminium. The brains of 4 individuals had at least one tissue with an aluminium content ≥5.00 μg/g dry wt. while 3 of these had at least one tissue with an aluminium content ≥10.00 μg/g dry wt. (Table 1). The mean (SD) aluminium content across all 5 individuals for each lobe were 3.82(5.42), 2.30(2.00), 2.79(4.05) and 3.82(5.17) μg/g dry wt. for the occipital, frontal, temporal and parietal lobes respectively. There were no statistically significant differences in aluminium content between any of the 4 lobes.

3.2. Aluminium fluorescence in brain tissues

We examined serial brain sections from 10 individuals (3 females and 7 males) who died with a diagnosis of ASD and recorded the presence of aluminium in these tissues (Table S1). Excitation of the complex of aluminium and lumogallion emits characteristic orange fluorescence that appears increasingly bright yellow at higher fluorescence intensities. Aluminium, identified as lumogallion-reactive deposits, was recorded in at least one tissue in all 10 individuals. Autofluorescence of immediately adjacent serial sections confirmed lumogallion fluorescence as indicative of aluminium. Deposits of aluminium were significantly more prevalent in males (129 in 7 individuals) than females (21 in 3 individuals). Aluminium was found in both white (62 deposits) and grey (88 deposits) matter. In females the majority of aluminium deposits were identified as extracellular (15/21) whereas in males the opposite was the case with 80 out of 129 deposits being intracellular. We were only supplied with 3 serial sections of each tissue and so we were not able to do any staining for general morphology which meant that it was not always possible to determine which subtype of cell was showing aluminium fluorescence.

Aluminium-loaded mononuclear white blood cells, probably lymphocytes, were identified in the meninges and possibly in the process of entering brain tissue from the lymphatic system (Fig. 1). Aluminium could be clearly seen inside cells as either discrete punctate deposits or as bright yellow fluorescence. Aluminium was located in inflammatory cells associated with the vasculature (Fig. 2). In one case what looks like an aluminium-loaded lymphocyte or monocyte was noted within a blood vessel lumen surrounded by red blood cells while another probable lymphocyte showing intense yellow fluorescence was noted in the adventitia (Fig. 2b). Glial cells including microglia-like cells that showed positive aluminium fluorescence were often observed in brain tissue in the vicinity of aluminium-stained extracellular deposits (Fig. 3, Fig. 4). Discrete deposits of aluminium approximately 1 μm in diameter were clearly visible in both round and amoeboid glial cell bodies (e.g. Fig. 3b). Intracellular aluminium was identified in likely neurones and glia-like cells and often in the vicinity of or co-localised with lipofuscin (Fig. 5). Aluminium-selective fluorescence microscopy was successful in identifying aluminium in extracellular and intracellular locations in neurones and non-neuronal cells and across all brain tissues studied (Fig. 1, Fig. 2, Fig. 3, Fig. 4, Fig. 5). The method only identifies aluminium as evidenced by large areas of brain tissue without any characteristic aluminium-positive fluorescence (Fig. S1).

Fig. 5. Lumogallion-reactive aluminium in likely neuronal and glial cells in the temporal lobe and hippocampus of a 14-year-old male donor (A10), diagnosed with autism. Intraneuronal aluminium in the temporal lobe **(a)** was identified via an orange fluorescence emission, co-deposited with lipofuscin as revealed by a yellow fluorescence in the non-stained autofluorescence serial (5 μm) section **(c)**. Intracellular punctate orange fluorescence (white arrow) was observed in glia in the hippocampus **(b)** producing a green autofluorescence emission on the non-stained section **(d)**. Upper and lower panels depict magnified inserts marked by asterisks, of the fluorescence channel and bright field overlay. Magnification ×400, scale bars: 50 μm. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

4. Discussion

The aluminium content of brain tissues from donors with a diagnosis of ASD was extremely high (Table 1). While there was significant inter-tissue, inter-lobe and inter-subject variability the mean aluminium content for each lobe across all 5 individuals was towards the higher end of all previous (historical) measurements of brain aluminium content, including iatrogenic disorders such as dialysis encephalopathy [13], [15], [16], [17], [18], [19]. All 4 male donors had significantly higher concentrations of brain aluminium than the single female donor. We recorded some of the highest values for brain aluminium content ever measured in healthy or diseased tissues in these male ASD donors including values of 17.10, 18.57 and 22.11 μg/g dry wt. (Table 1). What discriminates these data from other analyses of brain aluminium in other diseases is the age of the ASD donors. Why, for example would a 15 year old boy have such a high content of aluminium in their brain tissues? There are no comparative data in the scientific literature, the closest being similarly high data for a 42 year old male with familial Alzheimer's disease (fAD) [19].

Aluminium-selective fluorescence microscopy has provided indications as to the location of aluminium in these ASD brain tissues (Fig. 1, Fig. 2, Fig. 3, Fig. 4, Fig. 5). Aluminium was found in both white and grey matter and in both extra- and intracellular locations. The latter were particularly pre-eminent in these ASD tissues. Cells that morphologically appeared non-neuronal and heavily loaded with aluminium were identified associated with the meninges (Fig. 1), the vasculature (Fig. 2) and within grey and white matter (Fig. 3, Fig. 4, Fig. 5). Some of these cells appeared to be glial (probably astrocytic) whilst others had elongated nuclei giving the appearance of microglia [5]. The latter were sometimes seen in the environment of extracellular aluminium deposition. This implies that aluminium somehow had crossed the blood-brain barrier and was taken up by a native cell namely the microglial cell. Interestingly, the presence of occasional aluminium-laden inflammatory cells in the vasculature and the leptomeninges opens the possibility of a separate mode of entry of aluminium into the brain i.e. intracellularly. However, to allow this second scenario to be of significance one would expect some type of intracerebral insult to occur to allow egress of lymphocytes and monocytes from the vasculature [20]. The identification herein of non-neuronal cells including inflammatory cells, glial cells and microglia loaded with aluminium is a standout observation for ASD. For example, the majority of aluminium deposits identified in brain tissue in fAD were extracellular and nearly always associated with grey matter [19]. Aluminium is cytotoxic [21] and its association herein with inflammatory cells in the vasculature, meninges and central nervous system is unlikely to be benign. Microglia heavily loaded with aluminium while potentially remaining viable, at least for some time, will inevitably be compromised and dysfunctional microglia are thought to be involved in the aetiology of ASD [22], for example in disrupting synaptic pruning [23]. In addition the suggestion from the data herein

that aluminium entry into the brain via immune cells circulating in the blood and lymph is expedited in ASD might begin to explain the earlier posed question of why there was so much aluminium in the brain of a 15 year old boy with an ASD.

A limitation of our study is the small number of cases that were available to study and the limited availability of tissue. Regarding the latter, having access to only 1 g of frozen tissue and just 3 serial sections of fixed tissue per lobe would normally be perceived as a significant limitation. Certainly if we had not identified any significant deposits of aluminium in such a small (the average brain weighs between 1500 and 2000 g) sample of brain tissue then such a finding would be equivocal. However, the fact that we found aluminium in every sample of brain tissue, frozen or fixed, does suggest very strongly that individuals with a diagnosis of ASD have extraordinarily high levels of aluminium in their brain tissue and that this aluminium is pre-eminently associated with non-neuronal cells including microglia and other inflammatory monocytes.

5. Conclusions

We have made the first measurements of aluminium in brain tissue in ASD and we have shown that the brain aluminium content is extraordinarily high. We have identified aluminium in brain tissue as both extracellular and intracellular with the latter involving both neurones and non-neuronal cells. The presence of aluminium in inflammatory cells in the meninges, vasculature, grey and white matter is a standout observation and could implicate aluminium in the aetiology of ASD.

Abstract

The aim of this study was to investigate a previously overlooked, universally introduced environmental factor, fetal and retroviral contaminants in childhood vaccines, absent prior to change points (CPs) in autistic disorder (AD) prevalence with subsequent dose-effect evidence and known pathologic mechanisms of action. Worldwide population based cohort study was used for the design of this study. The United States, Western Australia, United Kingdom and Denmark settings were used. All live born infants who later developed autistic disorder delivered after 1 January 1970, whose redacted vaccination and autistic disorder diagnosis information is publicly available in databases maintained by the US Federal Government, Western Australia, UK, and Denmark. The live births, grouped by father's age, were from the US and Australia. The children vaccinated with MMRII, Varicella and Hepatitis A vaccines varied from 19 to 35 months of age at the time of vaccination. Autistic disorder birth year change points were identified as 1980.9, 1988.4 and 1996 for the US, 1987 for UK, 1990.4 for Western Australia, and 1987.5 for Denmark. Change points in these countries corresponded to introduction of or increased doses of human fetal cell line-manufactured vaccines, while no relationship was found between paternal age or Diagnostic and Statistical Manual (DSM) revisions and autistic disorder diagnosis. Further, linear regression revealed that Varicella and Hepatitis A immunization coverage was significantly correlated to autistic disorder cases. R software was used to calculate change points. Autistic disorder change points years are coincident with introduction of vaccines manufactured using human fetal cell lines, containing fetal and retroviral contaminants, into childhood vaccine regimens. This pattern was repeated in the US, UK, Western Australia and Denmark. Thus, rising autistic disorder prevalence is directly related to vaccines manufactured utilizing human fetal cells. Increased paternal age and DSM revisions were not related to rising autistic disorder prevalence.

Key words: Autism disorder, change point, vaccine, paternal age.

Epidemiologic and Molecular Relationship Between Vaccine Manufacture and Autism Spectrum Disorder Prevalence.

Deisher TA, Doan NV, Koyama K, Bwabye S.

Abstract

OBJECTIVES: To assess the public health consequences of fetal cell line manufactured vaccines that contain residual human fetal DNA fragments utilizing laboratory and ecological approaches including statistics, molecular biology and genomics.

METHOD: MMR coverage and autism disorder or autism spectrum disorder prevalence data for Norway, Sweden and the UK were obtained from public and government websites as well as peer reviewed published articles. Biologically, the size and quantity of the contaminating fetal DNA in Meruvax II and Havrix as well as the propensity of various cell lines for cellular and nuclear uptake of primitive human DNA fragments were measured and quantified using gel electrophoresis, fluorescence microscopy and fluorometry. Lastly, genomic analysis identified the specific sites where fetal DNA fragment integration into a child's genome is most likely to occur.

RESULTS: The average MMR coverage for the three countries fell below 90% after Dr. Wakefield's infamous 1998 publication but started to recover slowly after 2001 until reaching over 90% coverage again by 2004. During the same time period, the average autism spectrum disorder prevalence in the United Kingdom, Norway and Sweden dropped substantially after birth year 1998 and gradually increased again after birth year 2000. Average single stranded DNA and double stranded DNA in Meruvax II were 142.05 ng/vial and 35.00 ng/vial, respectively, and 276.00 ng/vial and 35.74 ng/vial in Havrix respectively. The size of the fetal DNA fragments in Meruvax II was approximately 215 base pairs. There was spontaneous cellular and nuclear DNA uptake in HFF1 and NCCIT cells. Genes that have been linked to autism (autism associated genes; AAGs) have a more concentrated susceptibility for insults to genomic stability in comparison to the group of all genes contained within the human genome. Of the X chromosome AAGs, 15 of 19 have double strand break motifs less than 100 kilobases away from the center of a meiotic recombination hotspot located within an exon.

CONCLUSION: Vaccines manufactured in human fetal cell lines contain unacceptably high levels of fetal DNA fragment contaminants. The human genome naturally contains regions that are susceptible to double strand break formation and DNA insertional mutagenesis. The "Wakefield Scare" created a natural experiment that may demonstrate a causal relationship between fetal cell-line manufactured vaccines and ASD prevalence.

Newborn immune activation may have long-term negative impact on brain function

New research shows that triggering the immune system in infant mice produces symptoms often seen in autism spectrum disorder and other developmental conditions

Date: January 12, 2018
Source: McLean Hospital

Summary: Neuroscientists have found that even a brief episode of immune system activation within days of birth can cause persistent changes in sleep patterns concurrent with increases in epilepsy-like brain activity -- a combination of symptoms common in autism spectrum disorder (ASD) and other developmental conditions.

FULL STORY

McLean Hospital neuroscientists have found that even a brief episode of immune system activation within days of birth can cause persistent changes in sleep patterns concurrent with increases in epilepsy-like brain activity -- a combination of symptoms common in autism spectrum disorder (ASD) and other developmental conditions. The detailed findings are available in the January 12, 2018, issue of Neuropsychopharmacology.

"A growing body of evidence suggests that immune system activation, such as that caused by bacterial and viral infections, can play important roles in many brain disorders," explained William Carlezon, PhD, chief of the Division of Basic Neuroscience at McLean Hospital, and senior author of the paper. "While previous research in laboratory animals has established that immune activation during critical prenatal (before birth) developmental periods can later produce the core features of ASD, including decreased social interaction, aberrant communication, and increased repetitive behavior, we wanted to evaluate whether postnatal (during infancy) immune activation could also produce other symptom clusters that are often seen in ASD and related conditions."

In humans, ASD is also frequently associated with certain co-occurring medical conditions, such as sleep disorders and seizures. To determine whether early postnatal immune system activation can produce these types of effects, McLean researchers treated mice with a lipopolysaccharide (LPS), a chemical that simulates a bacterial infection and causes a temporary (1-3 day) activation of the immune system. The LPS was given at a time point in mice (9 days after birth) that approximates the stage of brain development in humans at birth after full-term pregnancy. The mice were then implanted with micro-transmitters that enabled the researchers to collect an uninterrupted stream of data on sleep, muscle movement, and activity levels. Data collection continued through 12 weeks of age, a time point considered to represent adulthood in mice.

Carlezon, who is a professor of psychiatry at Harvard Medical School, and his team discovered that temporary immune system activation shortly after birth produced two main findings in the adult mice. First, immune-activated mice spent more time in slow-wave sleep, a sleep phase often associated with systemic inflammation. Second, the mice also showed dramatic increases in brief (lasting 2-3 seconds) bouts of abnormal brain wave activity. These events had the hallmark characteristics of spike-wave discharges (SWDs), a type of epilepsy-like brain activity that is not accompanied by full-body seizures. Although the SWDs occurred throughout the day, they were much more prevalent during periods when the mice were sleeping. When they occurred during wakefulness, they were accompanied by complete behavioral arrest -- a period of no movement throughout the body -- and immediately followed by recovery of normal brain activity and movement. Collectively, these findings demonstrate that even a brief period of immune system activation during critical periods of early development can leave a long-term signature upon the brain.

"The fact that immune system activation can produce these effects on its own, without any type of accompanying injury or trauma, provides new insight on the many paths that can lead to abnormal brain function" said Carlezon. "While there are clearly other factors that can cause these types of abnormalities, including genetic vulnerabilities, demonstrating that immune activation alone can produce these effects offers new hope for treatments that might reduce their severity, or prevent them altogether, in certain individuals."

While Carlezon's research focuses on animal models, his findings have implications for humans. The researchers believe that studying early developmental immune activation in mice may be valuable for diagnosing certain human illnesses and understanding how they develop. Persistent alterations in slow-wave sleep may represent a biomarker that could help differentiate immune-related neuropsychiatric conditions from those with other causes. Meanwhile, understanding epilepsy-like brain activity during both sleep and wakefulness may be useful in developing improved models of ASD. Studies in humans have shown that up to 60% of individuals with ASD experience SWDs during sleep, despite no diagnosis of clinical epilepsy, suggesting accuracy of the mouse model. The SWDs during wakefulness may resemble conditions such as "absence seizures" in humans, which are characterized by a brief loss of consciousness, a blank stare, and cessation of movement, and are often confused with inattention or intellectual disability.

"While more research needs to be conducted, these findings are a significant step forward in unlocking the mystery of ASD and other developmental disorders," said Carlezon.

Nine-year-old Hannah Poling is shown. (AP Photo/Atlanta Journal-Constitution, John Spink)

The first court award in a vaccine-autism claim is a big one. CBS News has learned the family of Hannah Poling will receive more than $1.5 million dollars for her life care; lost earnings; and pain and suffering for the first year alone.

In addition to the first year, the family will receive more than $500,000 per year to pay for Hannah's care. Those familiar with the case believe the compensation could easily amount to $20 million over the child's lifetime.

Hannah was described as normal, happy and precocious in her first 18 months.

Then, in July 2000, she was vaccinated against nine diseases in one doctor's visit: measles, mumps, rubella, polio, varicella, diphtheria, pertussis, tetanus, and Haemophilus influenzae.

Afterward, her health declined rapidly. She developed high fevers, stopped eating, didn't respond when spoken to, began showing signs of autism, and began having screaming fits. In 2002, Hannah's parents filed an autism claim in federal vaccine court. Five years later, the government settled the case before trial and had it sealed. It's taken more than two years for both sides to agree on how much Hannah will be compensated for her injuries.

Read Sharyl Attkisson's 2008 report on Hannah Poling

In acknowledging Hannah's injuries, the government said vaccines aggravated an unknown mitochondrial disorder Hannah had which didn't "cause" her autism, but "resulted" in it. It's unknown how many other children have similar undiagnosed mitochondrial disorder. All other autism "test cases" have been defeated at trial. Approximately 4,800 are awaiting disposition in federal vaccine court.

On July 20, 2010, respondent filed a Proffer on Award of Compensation (Proffer). On July 20, 2010, petitioners orally accepted respondent's Proffer. Based on the record a a whole, the undersigned finds that petitioners are entitled to an award as stated in the Proffer. Pursuant to the terms stated in the attached Proffer, the court awards petitioners:

1. A lump sum payment of $1,507,284.67, representing compensation for life care expenses expected to be incurred during the first year after judgment ($624,713.32), lost future earnings ($674,410.67) and pain and suffering ($208,160.68), in the form of a check payable to petitioners, as the court appointed guardian(s)/conservator(s) of the estate of Child Doe/77, for the benefit of Child Doe/77. No payments shall be made until petitioners provide respondent with documentation establishing that they have been appointed as the guardian(s)/conservator(s) of Child Doe/77's estate;

Time Magazine summed up the relevance of the Poling case in 2008: ...(T)here's no denying that the court's decision to award damages to the Poling family puts a chink -- a question mark -- in what had been an unqualified defense of vaccine safety with regard to autism. If Hannah Poling had an underlying condition that made her vulnerable to being harmed by vaccines, it stands to reason that other children might also have such vulnerabilities."

Then-director of the Centers for Disease Control Julie Gerberding (who is now President of Merck Vaccines) stated: "The government has made absolutely no statement indicating that vaccines are a cause of autism. This does not represent anything other than a very specific situation and a very sad situation as far as the family of the affected child."

Read the newly-released decision on Hannah Poling's compensation.

High Rates of Autism Found in Federal Vaccine Injury Program: Study Says More Answers Needed

By David Kirby

On Tuesday in Washington, members of the Elizabeth Birt Center for Autism Law and Advocacy (EBCALA), along with parents and children who received federal vaccine injury compensation, are having a press conference "to unveil an investigation linking vaccine injury to autism."

For the past two decades, according to the group, "the federal government has publicly denied a vaccine-autism link, while at the same time its Vaccine Injury Compensation Program (VICP) has been awarding damages for vaccine injury to children with brain damage, seizures and autism."

Their investigation, "based on public, verifiable government data, breaks new ground in the controversial vaccine-autism debate," and reports that "a substantial number of children compensated for vaccine injury also have autism — the evidence suggests that autism is at least three times more prevalent among vaccine-injured children than among children in the general population."

The following is a written Q&A conducted with EBCALA Directors:

Q) What is the Elizabeth Birt center, and who are the principal investigators on this project?

A) The Elizabeth Birt Center for Autism Law and Advocacy (EBCALA) is a nonprofit organization founded in 2008 to educate lawyers, advocates and parents about the legal challenges of autism (www.ebcala.org). The authors of this study are EBCALA board members. Mary Holland, Robert Krakow and Lisa Colin are attorneys and Louis Conte is a law enforcement officer who served as lead investigator.

Q) What were the main findings of this investigation?

A) The investigation found 83 cases of autism associated with compensated cases of vaccine-induced brain injury. It found that autism is at least three times more prevalent among vaccine injured children than among children in the general U.S. population today.

Q) How were the data compiled and analyzed?

We began collecting data over two years ago. We asked the federal government to provide us with this data through a Freedom Of Information Act request. We were told that our request would take four to five years, would cost $750,000, and would afford us incomplete information. We then assembled data about VICP decisions from legal databases and settlement information from publicly available docket reports. We found 21 published cases detailing autism spectrum disorders by name or description, which the study includes. We then interviewed families that we located through the docket reports. We trained interviewers to use a structured interview form for gathering information about the compensated cases. We also asked parents to complete standardized screening questionnaires for autism and to provide additional documentation. In these interviews, 62 families reported autism associated with vaccine injury.

Q) What evidence do you have that all these children actually received an ASD diagnosis?

A) In almost half the 83 cases, we have confirmation of autism beyond parental report, including medical and education records and completed standard autism screening questionnaires which are have a high degree of accuracy. The study calls for the complete medical review of all compensated cases of vaccine injury, including formal autism diagnosis, where appropriate.

Q) The government has conceded that vaccine injury can lead to brain disease (encephalopathy) and seizure disorders, but what scientific evidence is there to show that these injuries can result in autism symptoms?

A) This study is a review of decided and settled cases of vaccine-induced brain injury; it does not purport to be a scientific study. HHS or the Vaccine Injury Compensation Program compensated these cases based on the best available scientific information. Through interviewing the families of compensated claims, we have uncovered an association between vaccine-induced brain injury and autism. The article suggests that there is significant overlap between the definition of autism and the VICP's definitions of encephalopathy, seizure and sequela (resulting events).

Q) Don't these results simply suggest that children with ASD are more susceptible to vaccine injury than typical children? In others words, wasn't the injury an effect, rather than a cause of the ASD?

A) The parents interviewed in this study report that vaccines caused their children's autism as well as brain damage and seizures. The study notes a clear association between vaccine injury and autism in 83 compensated cases. The government has not previously brought this association to public attention. Whether this association between vaccine injury and autism is causal is one of the critical unanswered questions to which the study seeks answers. That is why the study calls on Congress to investigate further and to require full medical and scientific evaluation of all compensated claims of vaccine injury.

Q) Many critics say that it is easy to win a case in the VICP ("Vaccine Court") and that the legal standards of proof are much lower than in civil court. Dr. Paul Offit called it a "Kangaroo Court" after Hannah Poling won compensation for her autism and epilepsy (though he praised the court when it ruled against children with autism) — what is your response?

A) The VICP and HHS rely on the best science available in making compensation decisions. Proceedings are based largely on scientific and medical evidence in a field that the Court of Appeals for the Federal Circuit has described as "bereft of complete and direct proof of how vaccines affect the human body." Less than one in five claims in the VICP have received compensation. There is little question that those cases that have received compensation, including the 83 noted in our study, were the result of vaccine injury. Yet despite having received compensation, most of the families we interviewed were highly critical of the VICP, finding it to be exceptionally slow, parsimonious and hostile to petitioners.

Q) Critics also charge that these are merely legal decisions made by administrative judges, and not scientific conclusions based on rigorous analysis of all the existing data, and as such, they have no bearing on the debate about the causes of autism. Your reply?

A) We disagree. These compensation decisions are based on the best medical and scientific information available to the VICP and HHS. Many peer-reviewed scientific studies have used these compensated cases to elucidate the nature of vaccine injury. We have uncovered an association between vaccine injury and autism. Because we were only able to reach a fraction of the more than 2,500 individuals compensated for vaccine injury, we believe that we have identified the tip of the iceberg of this association. The study calls on Congress to investigate further and to ensure rigorous scientific analysis of all cases of compensated vaccine injury.

Q) Others contend that most of the seizure disorders reported in your paper were compensated following DTP vaccination, and that the government removed seizure disorders as an outcome of the DTP vaccine years ago after new evidence showed there was no association.

They contend that these cases should not have been compensated and do not provide evidence of an association between vaccines and autism, especially since many ASD children also suffer from seizure disorders. Your response?

A) Residual seizure disorder was removed as a presumption for vaccine injury from the VICP; that certainly does not mean that vaccines no longer cause seizure disorders in some children. In practice, the removal has meant that compensation for vaccine-induced seizure disorder is more difficult, but there have many compensated cases since that removal nonetheless. The study details compensation decisions before and after the removal of residual seizure disorder as a presumption for causation.

Q) How many of the cases you listed were for DTP vaccine, and what other vaccines were involved?

A) Diphtheria-petussis-tetanus (DPT) is the stated cause for 62 of the 83 cases; measles-mumps-rubella (MMR) makes up the next largest group, followed by cases caused by the diphtheria-acellular pertussis-tetanus (DpaT) vaccine.

Q) Many people will dismiss this paper as the act of desperate parents who willfully ignore all of the epidemiological studies done to date that show no link between vaccines and autism. Do they have a point? Again, why should anyone care about the legal proceedings of some obscure court when so much published science says otherwise?

A) Government officials in HHS or the VICP decided that the children in this study suffered vaccine injury based on science. We uncovered that these children also have autism. How can the government then continue to assert that there is no link between vaccines and autism? If in fact there is no link, why would there be even one case of vaccine-associated autism, let alone 83? The government itself is now calling for more research on vaccines and autism, including the VICP itself. Congress should investigate the vaccine-autism association in the VICP.

Q) In addition to being legal professionals and EBCALA board members, the authors are parents of children with an ASD diagnosis, and two of them have claims before the VICP. Does this bias the reporting and analysis of the study?

A) The two authors' pending claims on behalf of family members are disclosed; those claims are not the subject of this study in any way. The authors' experiences fuel their motivation in undertaking this investigation; they do not bias the study results which are based exclusively on government compensation decisions and structured interviews conducted by trained researchers. No attorney-authors conducted interviews with parents or caregivers; only trained non-lawyer researchers conducted interviews to avoid any possible conflict of interest.

Q) Where and when will this paper be published?

A) The article will be published on Tuesday, May 10 in the Pace Environmental Law Review at digitalcommons.pace.edu.

Q) What impact do you hope it will have?

The article calls on Congress to investigate the Vaccine Injury Compensation Program and to ensure that there is a medical review of all compensated cases of vaccine injury. We hope that the article leads to these results.

What is regressive autism and why does it occur? Is it the consequence of multi-systemic dysfunction affecting the elimination of heavy metals and the ability to regulate neural temperature?

Graham E. Ewing

Abstract

There is a compelling argument that the occurrence of regressive autism is attributable to genetic and chromosomal abnormalities, arising from the overuse of vaccines, which subsequently affects the stability and function of the autonomic nervous system and physiological systems. That sense perception is linked to the autonomic nervous system and the function of the physiological systems enables us to examine the significance of autistic symptoms from a systemic perspective. Failure of the excretory system influences elimination of heavy metals and facilitates their accumulation and subsequent manifestation as neurotoxins: the long-term consequences of which would lead to neurodegeneration, cognitive and developmental problems. It may also influence regulation of neural hyperthermia. This article explores the issues and concludes that sensory dysfunction and systemic failure, manifested as autism, is the inevitable consequence arising from subtle DNA alteration and consequently from the overuse of vaccines.

Keywords: autism, physiological systems, autonomic nervous system

Introduction

That the occurrence of autism has risen steadily in the last decades is not in dispute. Prior to the 1930's and the introduction of vaccinations autism was unknown. By 1968 in the UK, when Polio and DPT vaccines were given at 6 and 7 months autism was very rare. In 1988, when Polio and DPT was given at 3 months, DPT at 5 months and MMR at c13 months autism rates were still low. In 1996, when Polio and DPT/HIB injections were given at 2, 3 and 4 months, followed by MMR at c13 months autism rates began rising rapidly. By 2006 the occurrence of autism had reached pandemic proportions. In the period shortly before the 1980's the occurrence of autism was estimated to be circa 3-5 per 10,000; the majority having autism from birth[1]. Since the introduction of multiple vaccines the prevalence of autism has increased to an estimated 1 in 166 i.e. 60 per 10,000. Furthermore the trend is that of a continued increase. Some British teachers are claiming to see ASD in one in every 86 children[2]. This is supported by research which suggests that one in 100 British children may have some form of autism[3] and that ASDs are more prevalent than hitherto imagined[4] i.e. only severe cases of autism are recorded in the statistics. Such claims have been dismissed as mere speculation on the basis that there is not yet definitive proof of such claims however the perceived lack of evidence does not indicate that proof does not exist[5,6]. It may indicate that the understanding of the condition remains 'beyond the prevailing level of knowledge' (Table 1) [7].

By 1985 the incidence of regressive autism had equalled that from birth. By 1997 both types had increased although the regressive form was now >75% of the total occurrence. This suggests that an acquired condition was overtaking birth defects or purely genetic conditions. Autism affects four boys to every girl[10]. By contrast Autism appears not to occur in communities which do not use vaccines[11]. It occurs in immigrants from tropical climates who appear to have greater familial predisposition to autism[12] e.g. among Somali students in Minneapolis there was a rate of 1 in 28 (which compares with the local average of 1 in 56). This is more than five times the national rate of 1 in 150. Since the

1960's the number of vaccines given to a child before entering school has risen to c33. In children born to military families the occurrence of autism may now be as low as 1 in 67. In the vast majority of cases, the emergence of autistic indications appears to happen in children who had developed normally[10,13,14], and before three years[15,16]. The development of normal immune function appears to cease in the second year and is linked to the schedule of vaccines[17] and/or the MMR vaccine[18,19]. The consequences to society are estimated at c£2.4M in an autistic child's lifetime[20] which, if it continues to increase as many predict, will impose an unsustainable financial burden upon healthcare, education and social welfare systems.

The Systemic Nature of Physiology and Function

The body is a bio-dynamic, wholistic and systemic organism. It responds to sensory input which enables the autonomic nervous system thereby influencing behavior, the regulation of physiological systems, and function of the visceral organs (Fig. 1). The established association between visual perception, the autonomic nervous system, physiological systems, and biochemistry[21] raises issues which may be relevant to autism research.

- Different diseases are associated with differing colour perception[22] e.g. a yellow-blue deficit in diabetes[23], etc
- Different drugs are associated with altered color perception[24].
- Enzymes/Proteins are active in the visual spectrum[25,26].
- Suppressed immune function affects cognition[27]. In particular, t-cell deficiency (a common indicator of stress) is linked to cognitive dysfunction.

Any form of biochemical variation must therefore influence sense perception, sensory coordination and cognitive function. The existence of the physiological systems is not in doubt although there is not universal agreement on their structure. There is wide recognition that they regulate the function of organs (in each system), and that there are higher and lower levels for each system (homeostatic limits), however such systems remain an elusive and under-researched area of medicine. The Russian researcher I.G.Grakov[28,29] has mathematically modelled the consequences of cognition upon the autonomic nervous system and physiological systems. This included identifying and mapping the nature and structure of the physiological systems (Table 2).

Physiological Systems

Sleeping, Breathing, Digestion, Excretion, Osmotic Pressure, Blood Pressure, Blood Cell Content, Blood Volume, Blood Glucose , Sexual Function, pH, Temperature, Posture and Locomotion. See Table 2.

Such an explanation is highly inclusive and complete by comparison to the currently accepted but exclusive and limited explanation. The essential functions of temperature, sleeping and pH are now included; excretion is not limited to urination; whilst blood cell content (and other related systems) comprise what has hitherto been regarded as the immune system. Absorption of nutrients is influenced by system function including (but not limited to) blood pressure, blood volume, blood cell content, pH, temperature, etc. Elimination of toxins is similarly influenced by the complexities of system function.

The brain manages the autonomic nervous system and the function of the physiological systems. In addition, the brain waves are in a dynamic relationship with molecular biochemistry illustrating how drugs can be used to influence the body's biochemistry in order to act upon the symptoms of disease and how brain wave technologies such as neurofeedback can be used to alter the brain waves, physiological systems, organs, cells and molecular bio-chemistry.

Such systems regulate the function of the body's biochemistry e.g. (1) Most enzymatic reactions in the body are temperature dependent and catalysed by Magnesium. (2) The body requires maintenance of pH within a narrow operating range, and also the supply of minerals and vitamins/cofactors, to catalyse protein-substrate reactions in the body. (3) Appropriate blood volume, blood pressure, blood cell content and pH are required to ensure optimal absorption of minerals, vitamins, fatty acids from the intestines.

It is increasingly accepted that the synchronised activity of groups of neurons[30] in functionally coherent structures (the physiological systems), which exist in the brain and the body, synchronise their electrical impulses[31]. This may be evident when noting the evoked visual potentials, indicative of neural synchronisation, which are atypical in autism[32] and which may be part of the processes influencing sense perception (figure 1), sense coordination, memory[33], learning, etc. If so, this indicates that sensory input through the neurovisual pathways is integrated into actions, behaviour and movement and that learning requires synchronised activity between the brain, sensory

organs[34–36], and visceral organs. This is severely disrupted in the autistic[37]. Autism affects the function of all of the brain[38–40]. It is a neurobiologic, multi-systemic disorder i.e. affecting the function of every organ but not necessarily its structures[41]. It affects all aspects of the autonomic nervous system and hence influences all aspects of brain's function including that of neural networks involved in learning, memory, the function of the senses and the visceral organs.

The cerebellum, considered to be implicated in autistic spectrum disorders[42] comprises an estimated 50% of the brain's total processing capacity yet its role is not clear or understood[43]. It is involved in the accumulation of sensory data from the internal environment, including the organs in the body and those in the brain (including the sensory organs), thus distinguishing between sensory input from the external environment (a significant function of the cerebrum) and that of the biochemistry affecting the function of every organ (a significant function of the cerebellum), including the cerebellum. Such a role includes the processing, regulation and distribution of this data, through structures such as the Purkinje cells in the cerebellum which are attached by nervous structures to every part of the body. This includes the receipt of biosignals involved in the processes of movement, coordination and balance. Impaired flow of data to the brain via the cerebellum (and brainstem) may lead to functional problems affecting the body's fine control of e.g. balance, coordination, etc. Movement and balance involve the coordinated function of all body systems and organs and are coordinated by (1) sensory feedback from the external and internal environments and (2) the allocation of energy resources to and from each organ. They are dependent upon the precise nature, and timing, of data about each organ being provided to and by the cerebrum and cerebellum. This illustrates how the brain determines behaviour and actions appropriate to developing situations. It illustrates how changes at the organ, cell or molecular level influence brain function and vice-versa.

There are indications of cerebellar dysfunction in autism[44]. Inhibited flow of data to the cerebellum may be followed by developmental decay, cerebellar dysfunction[45,46], and reduced size of brain-stem. This is equivalent to the ‘use it or lose it’ phenomena affecting muscle tone and function.

Without cognitive input the brain cannot and does not function. Disease and drugs create cognitive dysfunction, altered sense perception, in particular affects visual perception. Accordingly, vaccines must also influence sense perception and coordination. Vaccines have a long-term influence and hence may have a more pervasive influence upon sense perception.

Our cognitive function depends upon the extent and coordination of sense perception i.e. between the eyes, ears, nose, mouth and skin. Genetic and/or environmental influences affect sense perception, the degree of sensory coordination and ultimately our connectedness with the surrounding world. Visual function is linked to the primary mechanism (rods, cones and pigments) but is also influenced at the biochemical level – noted by how pathology and drugs alter color perception[22,47] and affect the magnocellular and parvocellular neurovisual pathways which alter color perception and visual contrast. This influences the stability and function of the autonomic nervous system[48] and alters the processes of memory fixation, concentration, and behavior[49].

Anyone contracting disease e.g. measles, mumps, rubella, tetanus, etc; experiences altered visual perception therefore a weakened strain of the disease e.g. in vaccines, must also influence visual perception/cognition. Chronic disease is also accompanied by significant cognitive dysfunction and influences the coordination and processing of sense signals by the brain. The greater the number of illnesses, drugs or vaccines[50] the greater the alteration to the body's biochemistry therefore the greater its influence upon sense function and the degree of sensory distortion. It influences the autonomic nervous system and physiological systems and hence the coordination and function of every organ – visceral and sensory. This is a significant feature of autism[51,52].

Almost all diseases are linked to cognitive and behavioral disorders. Conversely, behavioral traits are influenced by biochemistry e.g. testosterone, oestrogen, cortisol, oxytocin, adrenaline, etc. Oxytocin influences the formation of social bonds influencing social engagement and attachment - which are dysfunctional in the autistic child[53–57].

Autonomic nervous system dysfunction?

In general problems with the stability of the autonomic nervous system[21,58] can be expected to be manifest as follows:

- Loss of Sense perception and Sensory Coordination
- System dysfunction (e.g. influencing breathing, blood pressure, heart rate, etc)
- Behavioural dysfunction (including learning problems, information feedback)

- Problems with Diet and Elimination (of toxins and wastes)
- Impaired and/or Delayed Neural Development
- Atypical brain waves

These are prevalent in autism.

Evidence of Systemic Dysfunction in Autism

Multi-systemic dysfunction is associated with a wide range of physiological disorders e.g. diabetes and obesity[59], cancer, cardiovascular disorders, pre-eclampsia, dyslexia[60], depression, etc. It affects the central[39] and autonomic nervous system in autistic children[61]. Systemic dysfunction in Autism includes that of temperature, blood cell content and immune function[62], blood pressure[63,64], digestion, excretion, posture and locomotion, sleep[65–67], pH, breathing; respiration rates, lower skin temperature. Each influences metabolic rate[68]. Autonomic dysfunction has also been linked to problems with appetite, swallowing food, nausea, recurrent vomiting, and abdominal bloating; constipation or diarrhoea; dry eyes, dilated pupils; dry skin, flushed skin following a meal, abnormal sweating, and unexplained high fevers; sleep apnoea, insomnia; bed-wetting, difficulty urinating, difficulty potty-training; altered perception of pain, sensory defensiveness, poor socialisation skills, anxiety, phobias, tics, emotional instability; and light intolerance. That autistic seizures are often linked to neural blood flow[69–71] is supported by fact that medications used to raise or lower blood pressure can alter the occurrence of seizures and improve sleep in the autistic child.

Autism affects sensory processing and sensory coordination[72] which is manifest in various ways e.g. tactile perception[73], vision[74], hearing[75], and smell. Autistic children may also display synaesthesia in which sensations become confused with one another[76]. Sounds may be experienced as touch or as visual stimulation e.g. autistic children may cover their eyes when they hear a loud sound. That autistic children have such sensory synaesthesia and sensitivity may indicate that their brains have extreme problems with sensory processing, regulation and coordination[77,78,60].

Vaccines and Vaccine Side-effects

Background The introduction of modified live viruses as vaccines enable the virus to attach its genetic material into the cell which replicates i.e. the host cell continues to function whilst producing the viral protein. This stimulates the production of antibodies. Under normal circumstances exposure to a viral disease would be countered (in vivo) at various levels enabling the body to steadily increase its immune response. By contrast, the injection of vaccines directly into the blood system overpowers the normal immune response leading to its rapid depletion. It is now suspected that long-term persistence of viruses and other proteins may produce chronic disease i.e. instead of producing a genuine immunity the vaccines are altering the body's systemic and biochemical stability, suppressing the production of differing types of white blood cells and hence immune function. Furthermore the introduction of many vaccines (up to 30 in a typical vaccination schedule) introduces a large number of foreign proteins which may be sufficient to ensure that immune function never returns to baseline and/or that immune biochemistry is fundamentally altered[62]. Consequently there now exists a growing concern which links immunizations to the huge increase in recent decades of auto-immune diseases[79] e.g., rheumatoid arthritis[80,81], multiple sclerosis, lupus erythematosus, lymphoma, leukemia, autoimmune demyelinative optic neuritis, diabetes mellitus, etc.

Vaccinations influence the balance of viral scavengers[82,83]. They suppress the production of b-cells, t-cells, etc. The synergistic action of these cells impairs antibody formation and becomes less effective in phagocytosis. This influences recognition of viral pathogens, leads to the progressive failure of immune function and hence to the increased incidence of auto-immune disease which we note as allergies[84–86] and immunodeficiency[87].

Some vaccinations have a greater effect than others e.g. Hib vaccine, pertussis vaccine[88–90], measles vaccine[91], etc. Indeed some articles indicate that the use of such vaccines can reliably induce asthma[92] by moderating adrenergic function[93].

Modified live viruses alter the structure and function of DNA. Each virus is a large molecule therefore its spatial arrangement must be influenced by its biochemistry which influences cross-helical structures and linkages within the DNA helix. Accordingly it is inevitable that the steady accumulation of such foreign proteins arising from an intensive vaccine programme will reach the stage where it significantly weakens DNA, gene, and chromosome structure and function. The prevailing reaction conditions - the consequence of protein expression which has been influenced by previous vaccines - will also affect the introduction of each modified live virus. Each will depress immune function. The

greater the number of viruses and foreign proteins (1) the greater the influence upon immune function and the time required for recovery from each vaccination; (2) the greater their influence upon DNA, gene and chromosome structure and function, the greater will be the risk of protein inhibition, system dysfunction, reproduction, etc.

The greater the amount of vaccines, introduction of foreign proteins and hence of alterations to the body's biochemistry the greater the risk that the body's immune function no longer recognizes or responds to existing vaccines or diseases[94] and/or that its immune response has been altered[95] and/or that sugar chains attached to an antibody alters its ability to bind to its receptors[96]. This may lead to mutated forms of disease[97–104] e.g. the reemergence of whooping cough[105], and a differentiated disease profile e.g. up to 30 per cent of individuals with a persistent cough are infected with B. pertussis[106]. Furthermore enhanced susceptibility to virus infection by vaccines is documented[107]. This could enable tougher strains to flourish[108].

Vaccines are not entirely safe. The currently used vaccines are merely less unsafe than previous vaccines[109,110] e.g.

- The Urabe strain of mumps vaccine in the MMR vaccine was replaced by the Jeryl Lynn mumps strain in response to reports from Japan linking the Urabe strain used, in the MMR vaccine, with high levels of meningoencephalitis.
- The Pluserix-MMR and Immramax-MMR vaccines were withdrawn because of reports of mild transient meningitis. The withdrawal of the smallpox vaccination led to a reduction in the incidence of TB.
- The Rubini vaccine continues to be used in some European territories although discredited[111].
- Leningrad-Zagreb strain is commonly used in developing countries, and may have superior efficacy when used during epidemics[112,113].
- Different strains of disease have different safety profiles[114]
- Different strengths of vaccine[115] carry risks which affect age groups or sexes differently.
- There are concerns over the use of whole-cell vaccines[116,117] although some argue that acellular vaccines are less effective[118].
- Sudden Infant Death Syndrome has been largely eradicated following withdrawal of the pertussis vaccine in Sweden and Japan.
- Side-effects arising from vaccination are associated with the onset of autoimmune disease[79,119], arthritis, diabetes mellitus, autoimmune demyelinative optic neuritis, etc.
- Sensory defects are a common side-effect of vaccines[120–122] e.g. sensori-neural hearing loss induced by the MMR vaccine.
- Drugs inhibit the effectiveness of vaccines (see 3.3.2). Systemic glucocorticoids (steroids) suppress the immune system and create risk of disseminated infection from live virus vaccines[123]. Vaccines may also be influenced by levels of immune function, dietary factors, and stress[124]. Many parents of autistic children and a number of medical experts believe the MMR vaccine is the culprit behind autism. In c15-20% of children it causes fever 7-12 days following immunization.

What are the risks from the diseases against which a vaccine is meant to protect?

Diphtheria, Polio, Tetanus, Meningitis, Pertussis Diptheria[125], Polio and Pertussis have largely been eradicated in the developed world although there may now be mutated forms of disease, a differentiated disease profile and/or an altered immune profile, which may be responsible for further outbreaks in vaccinated children and adults. Diphtheria is an upper respiratory tract infection characterized by sore throat and minor fever. It affects the central and peripheral nervous systems leading to deterioration of myelin sheaths, loss of motor control and sensation. Fatality rates are 5-10% although the rate of mortality may be higher for those under 5 years and over 40 years. It can be treated by antibiotics which prevent its transmission e.g. using erythromycin, procaine penicillin G, rifampin or clindamycin. Other minor complications including neck swelling, nausea, vomiting, listlessness, pallor, and a racing heart beat; lead to long term effects e.g low blood pressure, cardiac myopathy and peripheral neuropathy. Poliomyelitis is an infectious viral disease. Although c90% of polio infections are symptom-free, if the virus enters blood circulation this may lead to further complications. In c1% of cases, where the virus enters the central nervous system, it infects and/or destroys motor neurons thereby leading to muscle weakness and paralysis, usually involving the legs. Tetanus infection occurs through open wounds. It occurs commonly in hot, damp climates with soil rich in organic matter. It creates muscle spasms in the jaw, difficulty in swallowing, muscle stiffness and spasms throughout the body. The neonatal form of the disease is a

significant public health problem in the developing and/or agricultural economies. There are about one million cases of tetanus reported each year, mainly in the developing world, causing an estimated 300,000 to 500,000 deaths. In the United States, there are about five deaths from tetanus each year. Tetanus is the only disease that is infectious but not contagious. Pertussis is a highly contagious disease. There are 10–90 million pertussis cases and about 600,000 deaths per year. Sixty percent of all cases occur in the developing world. In children it is characterized initially by mild respiratory infection symptoms before developing into the characteristic 'whooping' cough. Other complications may include encephalitis, pneumonia, and secondary bacterial infections. Naturally-acquired disease caused by Hib (H. influenza) appears only to occur in humans with low natural immunity[126]. In infants and young children, H. influenza type b may cause pneumonia, and acute bacterial meningitis. Both H. influenza and S. pneumonia can be found in the upper respiratory system of humans i.e. both reside naturally in the body. Alterations in the immune response; attributed to poor nutrition, stress or transmission; enable their proliferation with potentially serious outcomes.

Measles, Mumps and Rubella Measles is largely a consequence of compromised immunity arising from poor diet and is linked to high levels of mortality[127] in the developing world. In developed countries, most children are immunized against measles by the age of 18 months, generally as part of the triple vaccine treating measles, mumps and rubella (children younger than 18 months usually retain measles antibodies (Immunoglobulins (Ig)) transmitted from the mother during pregnancy). The rate of mortality from measles is typically 0.3% however in the developing world this may be as high as 28%. The classical symptoms of measles are typically fever (up to 40C), cough, coryza and conjunctivitis. Complications include mild diarrhoea, pneumonia, encephalitis, SSPC, and corneal ulceration or scarring. They are usually more severe amongst adults. Permanent hearing loss or damage to vision is recognized complications of measles. Measles has been known to occur in children with congenital rubella syndrome, and has been implicated in the etiology of inflammatory bowel diseases (IBDs). The more common symptoms of mumps are parotitis, fever (typically 38.3C), headache and orchitis[128] Other symptoms of mumps include sore face and/or ears, and loss of voice. Known complications of mumps include infection of other organ systems, sterility in older men, mild forms of meningitis, encephalitis, sensorineural hearing loss, pancreatitis, inflammation of the ovaries, and risk of spontaneous abortion during pregnancy. Rubella is a mild disease which often passes unnoticed[129]. The primary reason for the introduction of a vaccine is to prevent infection during pregnancy. The common symptoms of rubella are the appearance of a rash on the face, trunk and limbs (after an incubation period of 14-21 days) which usually fades after several days. Other symptoms include fever (typically 38C), swollen glands (post cervical lymphadenopathy), joint pains, headache and conjunctivitis. Rubella is generally a mild disease, rare in infants or those over the age of 40. The older the person the more severe the symptoms e.g. some women experience arthritis type symptoms. Children exposed to rubella in the womb may show developmental delay, inhibited growth, hearing disabilities, diabetes, glaucoma, schizophrenia, etc. If infected during the first 12 week period of pregnancy this may lead to congenital rubella syndrome (CRS), which is manifest as a series of complications including spontaneous abortion and, in the neonate: cardiac, cerebral, ophthalmic and auditory side-effects. Known complications include prematurity, low birth weight, and neonatal thrombocytopenia, anemia and hepatitis. CRS is the main reason a vaccine for rubella was developed. It increases the risk of miscarriage or still birth in mothers who contract rubella shortly before or early in pregnancy. If the baby survives, it may have heart disorders, blindness, deafness, etc. CRS is manifest as sensorineural deafness, eye problems, heart disease. Other complications include low birth weight, mental retardation, problems with the spleen, liver and bone marrow, etc. Hepatitis B is difficult to catch and comes from blood or sexual contact with an infected carrier. Further, vaccine-derived immunity is thought to be short-lived. Hpv , an infection transmitted during sexual intercourse, clears naturally after several months/years. Mumps and Rubella may occur without the patient being aware that they have the disease.

Some diseases may confer natural immunity e.g. the mumps virus may confer a degree of immunity against ovarian cancer[130–133].

In summary, disease side-effects reflect the effect of the disease upon the body's functional systems i.e. upon temperature, digestion, excretion, etc. Typical viral fevers are circa 1-2C above the body's normal body temperature. Measles is particularly noteworthy because fever may reach 40C (or higher), some 3-4C above normal body temperature and just 1C below the point where proteins denature and at which brain death commences.

What are the risks from the Vaccine? Typical vaccine side-effects There is evidence that BCG and measles vaccinations administered singly reduce child mortality[134] but that this is unrelated to the incidence of measles or measles deaths[135,136]. By contrast the pertussis vaccine is associated with a negative effect[137].

Dtap: Recorded common side-effects with the DtaP vaccine include fever, tiredness, poor appetite, vomiting and inflammation. Less common and more severe side-effects include distress (crying), seizures, lowered consciousness or coma, brain damage.

MMR: Recorded common side-effects with the MMR vaccine include fever, swelling of the lymph glands, tiredness, poor appetite, and abhorrence of bright lights. More severe problems include low platelet count, pain and stiffness in the joints/inflammation. Less common and more severe side-effects include distress (crying), seizures, deafness, lowered consciousness or coma, brain damage.

Tdap: Recorded common side-effects with the Tdap vaccine include pain, chills, fever, headache, tiredness, poor appetite, stomach ache, vomiting, diarrhoea and inflammation

The above listed vaccine side-effects are indicative of systemic instability affecting most physiological systems – temperature (chills and fever), excretion (inflammation of the lymph glands), blood cell content (low platelet count), excretion (diarrhoea), digestion (poor appetite, vomiting), sleep (coma), and metabolic rate (tiredness, lowered levels of consciousness). In addition there is evidence of altered sense perception, indicative of problems with the autonomic nervous system, which affects hearing, visual perception (abhorrence of bright lights), smell and touch.

Significant vaccine side-effects have been linked to swine flu vaccine (Guillain-Barre paralysis); in RSV vaccine[138]; in the measles, mumps and MMR vaccines[139]; hepatitis A and B vaccine[140]; tetanus vaccine; smallpox vaccine; polio vaccine; pertussis vaccine[141], etc. The incidence of vaccine side-effects may now be sufficiently great to question the claims that the risks from the disease exceed that of vaccines[109].

The MMR vaccine has been linked to autism, Crohn's disease, inflammatory bowel disease[142,143] and other serious chronic stomach problems[144], epilepsy, brain damage including meningitis[145,146], cerebral palsy, pancreatitis[147] and diabetes mellitus[148–150], encephalopathy, encephalitis[151,152], hearing and vision problems, arthritis, behavioural and learning problems, chronic fatigue syndrome, diabetes, Guillain-Barre syndrome, idiopathic thrombocytopaenic purpura, subacute sclerosing panencephalitis (SSPE), leukaemia, multiple sclerosis, and death.

There is evidence that in cases of immune deficiency that viruses continue to persist in the body[143,153–155]. The measles virus is known to persist in patients with subacute sclerosing panencephalitis (SSPE), measles inclusion body encephalitis (MIBE)[156] and multiple sclerosis[157]. Since the introduction of measles vaccines, vaccine-associated SSPE has increased in the USA. Furthermore patients with B or T-cell immunodeficiencies have cognitive side-effects[27] and are advised against vaccination due to the risk of severe and/or fatal infection (Merck). That viruses persist in the body and are linked to autoimmune disorders is a feature of rubella virus[158–160], anthrax vaccination[161], hepatitis B[162], etc. There is a reported increased risk of death with combined vaccination DPT and polio[134].

In summary, vaccine's side-effects reflect the vaccine's influence upon the body's functional systems i.e. upon temperature, digestion, excretion, blood cell content, etc.

The Cumulative Effect of Vaccines There is concern that the cumulative effect of vaccines upon the body's function has not been properly assessed[137]. Unvaccinated children appear to have less exposure to disease[84,85], delaying vaccination reduces exposure to disease[163], contracting the disease naturally leads to less disease in future[164], and that excessive vaccination is considered ineffective and dangerous[165].

Vaccine-vaccine and Vaccine-drug interactions In general, vaccines may be influenced by antibiotics[166], immunoglobulins, immunosuppressants, monoclonal antibodies, anticoagulants and corticosteroids. The interaction between a vaccine and a drug has been reported only with influenza vaccine and four drugs (aminopyrine, phenytoin sodium, theophylline, and warfarin sodium), and with BCG vaccine and theophylline. The clinical significance of vaccine-drug interactions is not fully determined[167]. There is further evidence of interactions involving most vaccines e.g. HPV Vaccine: (http://hpv.emedtv.com/hpv-vaccine/drug-interactions-with-the-hpv-vaccine.html); Shingles Vaccine: An Introduction: (http://senior-health.emedtv.com/shingles-vaccine/drug-interactions-with-the-shingles-vaccine.html); yellow fever vaccine; polio vaccine (neomycin, streptomycin, phenoxy ethanol, formaldehyde), rotavirus vaccine, etc.

Vaccines are not subject to double blind clinical trials despite the evidence of vaccine-drug interactions and perhaps also of vaccine-vaccine interactions.

Effectiveness of Vaccines/Vaccines are not 100% effective Whooping cough is becoming increasingly prevalent[168–170]. Although claimed to be 88 per cent effective among children of 7-18 months, during a nationwide epidemic of whooping cough in 1993, a group of researchers discovered that 82 per cent had completed their full complement of DPT vaccines[171]. Others have commented that the whooping cough vaccine is only to be 36% effective[109].

Many studies show that the measles vaccine isn't completely effective[172–175] and that a significant proportion of those infected in measles outbreaks (>60%) had been vaccinated. There is also a lack of consensus concerning the effectiveness of whole or acellular vaccines, each having their own side-effects and effectiveness[176] e.g. vaccine efficacy was estimated at 75.4% for an acellular 5 component vaccine, 42.4% for an acellular two component vaccine and 28% for a whole cell DTP vaccine[177]. The whole-cell vaccine was associated with different levels of side-effects including significantly higher rates of crying, cyanosis, fever, and local reactions than the other three vaccines.

There is evidence of declining vaccine immunity[178] illustrated by transmission of mumps[179], measles[180,181], rubella[182], polio[183], Hib[184,185], Hepatitis B[186,187], smallpox, diphtheria, varicella[188], whooping cough[189], etc.

Effect upon Learning One in 14 children i.e. up to half of all children starting school, have problems with speech, language and communication[190]. Is this significant bearing in mind[4] that the occurrence of autism may be more widely spread than has hitherto been considered possible i.e. that only the most severe and chronic cases of autism are recorded? Learning problems are a significant problem in autism[191]. It affects the body's processing of data from the external and internal environments. This affects, in the autistic, the ability of the autonomic nervous system to regulate organ function and hence influences their ability to make sense of the external world. The problem may be part of a spectrum of biochemical disorders[60] influencing all aspects of the learning process e.g. including memory, concentration, sense perception and sense coordination.

Biochemical Evidence

Biochemical Instability Indications of almost complete physiological instability are manifest in the autistic as a proliferation of biochemical deficiencies e.g. (1) Fatty acid deficiency[192]; (2) a distinctly different immune response[62] including reduced natural killer cell activity[193], decreased immunoglobulins and T cells and altered lymphocyte functions[194,195–197], (3) Vitamin D deficiency[198]. Vitamin D regulates the levels of glutathione which may explain the link between heavy metals and autism. Depleted levels of glutathione increase oxidative stress, suppress the detoxifying effect of liver enzymes e.g. P450, reduce the elimination of heavy metals, and increase the neurodegenerative effects of heavy metals. Mercury inhibits the enzyme methionine synthase which converts homocysteine into methionine. Accordingly, levels of cysteine, glutathione and metallothionine are low. This illustrates that the methionine pathway may be faulty in many with autism and supports earlier suggestions that redox imbalances[199–200] and detoxification are impaired. (4) Vitamin A deficiency[201–202] is a commonly observed symptom of measles. The severity of complications have been linked to the degree of Vitamin A deficiency; (5) Carnitine deficiency[203]; (6) increased norepinephrine levels and decreased dopamine-hydroxylase activity[204]; (7) demonstration of inter- and intra- species differences in serotonin binding sites by antibodies from an autistic child[205]; (8) the levels of gut flora[206]; (9) Enterocolitis in Children with Developmental Disorders[207]; (10) Adenosine Deaminase Activity Decreased in Autism[208,209]; (11) Small intestinal enteropathy with epithelial, IgG and complement deposition in children with regressive autism[210]; (12) Mitochondrial disorder[211]. Findings suggest that mitochondrial dysfunction, including abnormal enzyme function, mitochondrial structure, and mitochondrial DNA integrity, may be present in children with autism[212].

Other biochemical deficiencies/chromosomal abnormalities include:

Phosphoribosylpyrophosphate (PRPP) synthetase superactivity, Adenylosuccinate lyase deficiency, Histidinemia, Lesch-Nyhan disease, Fragile X syndrome, Rett Syndrome, Dihydropyrimidine dehydrogenase (DPD) deficiency, Tuberous sclerosis, Superactivity of pyrimidine 5'-nucleotidase (P5N), etc.

The use of Drugs Biochemical instability is a feature of autism. Accordingly, drugs are used to mitigate autistic symptoms e.g. (1) Lofexidine[213] has been shown to improve prefrontal cortical function in nonhuman primates. This is consistent with the view that the prefrontal cortex regulates executive/system function. (2) An open trial[214] suggested that methylphenidate use in autistic hyperactive children may ameliorate hyperactivity, and impulsivity in autistic children. (3) Neuroleptics e.g. haloperidol, are mildly effective in reducing hyperactivity, impulsivity, and inattention in children with autistic disorder[215]; clonidine is used in the treatment of tic disorders and ADHD[216]. Other drugs used include Tianeptine[217]; Galanthamine[218]; Immunoglobulins[219]; melatonin[220]; and beta-blockers[221].

The Cause of Autism The occurrence of autism is due to a significant genetic insult[222] but it is not considered to be an inheritable condition. How and when this occurs can be debated however, for a young child with a developing immune system, there are few factors which could be held responsible other than vaccines and/or the related and damaging effect of exposure to high levels of mercury. No other factor or explanation has been offered as a viable alternative explanation for the occurrence of regressive autism. The evidence indicates there is alteration to

chromosome structure and/or function. It indicates the influence of external stressor(s) influencing mitochondrial structure and DNA, chromosomal instability and translocation, which ultimately influences protein expression. The combined effect influences system stability, organ function, the prevailing levels of biochemistry, sense perception, behavior, etc. It influences protein expression and the rate and completeness of subsequent protein-substrate reactions leading to lowered immune function, reduced absorption of nutrients, slowed metabolism, impaired development[262], etc; i.e. the body's biochemical processes do not proceed as they should.

Is this an indication of chromosomal damage?

Viruses are able to infiltrate cells, inserting their genetic material into them. As outlined earlier (see 4.1) there are biochemical markers of vaccine damage. That it affects four boys to every girl[10] illustrates that the condition is largely due to a defect with the X-chromosome and leads to consideration of the factors which could influence at the genetic/chromosomal level. In general, chromosomal damage is linked to radiation e.g. due to adverse nuclear events which leads ultimately to birth defects. The prevailing evidence appears to suggest the influence of e.g. proteolytic enzymes or temperature[223,224] which may alter chromosome structure. Little evidence has been offered for the 1 in 5 occurrence experienced by girls although this appears likely to be the consequence of a chromosomal stressor.

It is widely recognised that genetic predisposition and protein expression can be influenced by environment influences[7], and that genetic damage can be the result of exposure to radiation, however the evidence being offered appears to suggest a subtle form of genetic alteration - associated with the wider use of vaccines[17] - which may not necessarily be inherited but is responsible for altered system stability and function and consequently of altered biochemistry and function. There is evidence that system function is intact but dysfunctional i.e. that homeostasis is severely compromised. Such findings are supported by research into Gulf-War Syndrome (GWS) in which[225] untypical RNA was found in the blood of sick GW veterans. This illustrates that the viral encephalopathies originated from RNA-viruses and hence from vaccines. That immunosuppression, shown to be a factor in GWS[226] and autism, is associated with the concentrated use of vaccines[227] is further supported by the fact that French soldiers who were not vaccinated yet who served in the gulf war did not get GWS however American and British soldiers[228], irrespective of whether they served in Iraq or not, reported a significantly greater incidence of autistic-spectrum disorders and GWS.

The Effect of Heavy Metals

Heavy Metals and Mercury in particular, affects the function of the CNS and are extensively documented and associated with autism[229]. Amongst a variety of side-effects mercury decreases lymphocyte viability, and in the brain: dysfunction in the amygdala, hippocampus, basal ganglia, and cerebral cortex; destruction of neurons in the cerebellum; and brainstem abnormalities. Demyelination is evident in such conditions. The brain's electrical patterns are similarly abnormal.

A note on the following paragraph: Mercury was removed from vaccines except for multidose flu vaccines. Subsequently, the use of aluminum as an adjuvant in vaccines, began to increase. The mechanism of aluminum neurotoxicity is similar to that of mercury.

The most significant contributors to the increased mercury burden are: Mercury in vaccines (e.g. DTP (at typically 25 micrograms of mercury per dose), Tetanus, Hepatitis B & (most) influenza vaccines), contamination of fish[230], wild/bush fires; and emissions from power stations[231] and industrial chimneys including incinerators, waste-burning cement works, crematoria, etc. The characteristics of autism and mercury poisoning are extremely similar which suggests that autism arises from mercury poisoning[232,233]. Children with autism have greater amounts of mercury and other heavy metals in their system[234]. For these children the exposure route is considered to be predominately via childhood vaccines, most of which contain thimerosal. Vaccinated children of circa 10-20 kgs are exposed to an adult overdose of mercury, over 62.5 micrograms of mercury within the first three months, which significantly increases a child's risk of developing some form of neuro-developmental disorder such as impaired development, speech and language, autism, stuttering and attention deficit disorder.

Children living downstream of coal-fired power stations have a greater incidence of autistic spectrum disorders[231]. This indicates that the innate physiological processes, which the body uses to eliminate heavy metals, are being overcome by overexposure.

Mercury poisoning is an insidious process. In general the symptoms do not appear immediately upon exposure, although they may in especially sensitive individuals or in cases of excessive exposure. The initial preclinical stage is followed by the development of symptoms of mercury poisoning over a period which may last from weeks, months, and years[235–237]. Consequently, mercury given in vaccines to very young children would not be expected to lead to a recognizable disorder, except for subtle signs, before age 6-12 months, and might not emerge for several years[233].

In autistic children, the initial signs occur shortly after the first injections, and consist of abnormalities in motor behavior and in the sensory systems, particularly touch sensitivity, vision, and numbness in the mouth[15,238]. These signs are followed by parental reports of speech and hearing abnormalities appearing before the child's second birthday[10]. Finally, there is the development of autistic-like traits and a continuing regression or lack of development in subsequent years. These symptoms change[239] depending upon the circumstances surrounding each child.

Most autistic children have impaired liver detoxification. Many have low levels of metallothionine, conceivably the consequence of a deficiency of Zinc, which is indicative of a lowered capacity to chelate mercury and other heavy metals. Mercury is a powerful oxidant which depletes cellular antioxidants, especially glutathione. The P450 detoxifying enzymes of the liver rely heavily on adequate availability of glutathione. EthylMercury the active component in thimerosal causes apoptosis of the t-cells[240–242].

Although the withdrawal of mercury from vaccines has not resulted in an overall decline in the occurrence of autism this does not mean that the problem does not lie with thimerosal[243,263]. It may indicate that the problem is associated with the elimination of mercury[244] i.e. affecting function of the lymphatic system and excretion[245]. This is supported by noting evidence of urea cycle dysfunction. Problems with the urea cycle, conceivably the consequence of mercury poisoning, have been linked to autism. A child with ornithine transcarbamylase (OTC) deficiency is likely to be lacking in energy, have appetite problems, poorly-controlled breathing rate and/or body temperature, and slow development. Significantly, OTC deficiency is an X-linked recessive disorder (http://www.merck.com/mmpe/sec13/ch164/ch164a.html) one of a number of primary immunodeficiencies associated with vaccine use.

As in autism, onset of Hg toxicity symptoms is gradual in some cases, sudden in others[232,233]. In the case of poisoning, the first signs to emerge are abnormal sensation and motor disturbances. As exposure increases, these signs are followed by speech problems, and hearing deficits[246]. Upon removal of the mercury the symptoms tend to recede except in instances of severe poisoning, which may lead to death[232]. As in autism, epilepsy arising from Hg exposure is also associated with a poor prognosis[247]. Mercury acts upon the catecholamines and influences the function of the autonomic nervous system[245]. This affects cognitive performance[248], spatial vision[249], etc.

Other metals have been implicated in adverse neurodevelopmental outcomes in children e.g. lead and mercury[250,251], with exposure to cadmium, arsenic, antimony and chromium also a concern. Studies have found adverse effects of prenatal lead exposure on growth and development, but little research has examined an association with autism. Whilst Mercury is of concern, because of evidence for neurotoxic effects and the fact that it has become so prevalent in the wider environment[250], Aluminum also shares common mechanisms with mercury e.g. it interferes with cellular and metabolic processes in the nervous system. Children given the recommended vaccinations are injected with nearly 5 mg of aluminum by the time they are just 1.5 years old, almost 6 times the safe level. Furthermore the nature of the Aluminium affects the prevailing blood levels and is also increasingly implicated, through their use as vaccine adjuvants, in autism[252].

Current Therapeutic Approaches used to Treat Autism

There is evidence that autism is a treatable disease and that some therapies can mitigate the effects of autism[253,254]. Although there is no recognised method of treatment, or of significant and/or proven outcomes, autistic children appear to respond to therapies which enhance the function of the breathing , to enhance oxygen levels[255], and excretory system e.g. by osteopathy[256]. Moreover a commonly observed side-effect with autistic children is that when a child has an elevated temperature, perhaps resulting from a fever, the autistic symptoms appear to recede and the child behaves normally[41]. Autistic children suffer from adverse sleep patterns. In the US autistic children are often treated by chelation therapy and biofeedback[257–259].

Dysfunction of the Excretory or lymphatic system leads to long-term exposure to mercury which under normal circumstances would have been rapidly eliminated from the body. This may also lead to higher neural temperatures which will inevitably influence brain function.

Further evidence of biochemical deficits[260] and of the benefit of biochemical based supplements e.g. vitamin B6 and magnesium; melatonin; methylcobalamin; vitamin A, C & D supplements; dimethylglycine (DMG) and trimethylglycine (TMG). DMG provides building blocks that are required for purine nucleotide synthesis. DMG comes from TMG when TMG methylates homocysteine. Significantly, absorption of Vitamin A Palmitate requires an intact gut mucosa at the appropriate pH and in the presence of bile for metabolism. Many autistic children have damaged mucosal surfaces therefore they have impaired capacity to absorb vitamin A[261].

That some children can become normal when their temperature increases above normal levels e.g. due to a viral infection,[41] may illustrate that the levels of the homeostatic mechanism affecting the physiological systems have been reset at what can be considered to be abnormal levels[47]. This may indicate that autism is treatable - perhaps to a greater degree than has hitherto been considered possible.

Discussion

The mass of scientific evidence compiled by researchers clearly indicates that the incidence of autism occurs following vaccination and is most closely associated with the schedule of vaccines culminating in the MMR vaccine. That vaccines suppress natural immune function is not in dispute e.g. those with naturally low levels of immune function (immigrants from tropical climates) show greater predisposition to autistic spectrum disorders.

The immediate effect arising from vaccination influences gene function and protein expression. This leads to lower levels of white blood cells including e.g. lymphocytes, immunoglobulins, t-cells, b-cells and/or neutrophils, and disturbs their synergistic action and hence their ability to memorize and respond to immune responses when challenged. This impairs the ability to kill pathogens thereby predisposing to further infections. The short and long-term outcome is to the neural mechanisms regulating system function affecting e.g. pH, the excretory system, temperature, and the elimination of toxins and heavy metals. This explains why the discontinuation of thimerosal in vaccines was followed by a steady increase in the incidence of autism and hence that researchers did not find a correlation between the incidence of autism and the use of thimerosal-containing vaccines[263]. This may also explain the effect of multiple vaccines, in particular the MMR vaccine, and the greater predisposition to autistic spectrum disorders in military families.

In most autistic children brain structures are initially unaffected but become steadily underdeveloped as a consequence of exposure to mercury and other heavy metals. This evolves into a neurodevelopmental problem leading to chromosomal abnormalities, affecting myelination, the subsequent degeneration of the cerebellum, etc.

The MMR triple vaccine may inhibit normal immune function which, directly or indirectly, ultimately leads to chromosomal and/or genetic damage and/or dysfunction. The occurrence of GWS in adults, a condition with many features which are common with autism, indicates the problem may be due to the number and/or intense schedule of vaccinations however this does not excuse the measles or MMR vaccine from suspicion. The combined vaccine raises body temperature whilst lowering immune and system function. This may make a mild measles vaccine more virulent which may increase fever to an abnormally high level. It suggests (1) single vaccines may pose less risk than triple vaccines; (2) some vaccines pose a greater risk than others e.g. pertussis and measles; and (3) the way in which vaccines are administered will be accompanied by different side-effects e.g. if pertussis is followed by measles or vice-versa, if BCG gives a beneficial effect to be followed by pertussis, if vaccines are given in combination, etc. Increased disease loading is the inevitable consequence of multiple vaccine or lots of single vaccines or triple vaccines e.g. of asthma, autoimmune disease, etc. It suggests that adherence to the vaccine schedule is the problem – too many vaccines, too quickly.

Vaccines cause an inflammatory response in some e.g. for those with an inadequately developed or artificially lowered immune system, for those genetically predisposed, or perhaps due to viral or bacterial infection. This creates genetic damage and/or dysfunction and hence influences the brain's ability to regulate the physiological systems, and especially to the lymphatic system and its ability to excrete mercury and heavy metals, would lead to long-term damage and problems processing sensory/cognitive input. This would inevitably affect the brain's ability to maintain a regulated temperature below that which affects brain damage (41° C). This inevitably influences the autonomic nervous system and the stability of all related physiological systems including temperature, blood pressure, blood cell content, blood glucose, digestion, excretion, sleeping, etc.

Further evidence of multi-level dysfunction is evident from unusual brain-wave stability, aberrant sleep patterns, loss of sense perception and coordination, mirror neuron dysfunction, lower pain thresholds, mental and physical deterioration, short periods of concentration, etc. That it is a problem of systemic dysfunction is further supported by noting how it can be treated using sensory therapies which may facilitate the re-establishment of some degree of physiological stability.

Where is the proof that vaccines are safe? The argument has never been that they are completely safe but that the consequences are less than having the disease. Now it is illustrated that the consequences of intensive vaccination schedules pose a greater risk than could ever have been imagined. This leads to the evolution of new viral strains, an unsurprising development when the environment to which it is exposed is being altered by new proteins, structural variants and altered DNA.

Vaccines are an essential component of preventative healthcare however it may be necessary to review the ways in which vaccines are used, administered and regulated[141,264] i.e.

- As drugs are tested in the clinical environment to assess their interaction with other drugs, the cumulative use of vaccines including that of multiple vaccines should be researched and shown, through double-blind placebo controlled clinical trials, to be free from any such interactions i.e. of one single vaccine with another single or multiple vaccine or drug. It has been considered unethical to select a control group of children which would otherwise not be vaccinated yet such is the levels of conscientious objectors in the industrialized world and through circumstances of impoverishment in the underdeveloped countries that such statistics must currently exist.
- Measures to assess the suitability of children for vaccination i.e. how to assess whether a child has a greater predisposition to an adverse vaccine reaction and the subsequent development of autism?[265]
- The time when vaccinations should be given and the time between vaccinations e.g. giving mumps and rubella vaccinations later in childhood.
- Are some vaccines necessary in the industrialized world e.g. mumps, rubella, Hib, Hpv, etc? With more than 200 other vaccines under development this must be an issue of review.

The risks from disease and vaccinations differ upon location. In the developed world, there is an estimated 0.1-0.3% risk of mortality from measles which compares with a 0.6% risk and rising (with some estimates at 1-2%) of autism. This excludes the cost of treating the wide range of side-effects which must clearly be attributed to the use of vaccines. The cost of treating vaccine-related side-effects may now be far greater than the diseases against which the vaccine(s) were designed to protect. Furthermore, in the developed world there is a highly developed social structure which is able to assist parents to deal with the condition. By comparison, what are the implications for an autistic child in the developing world where there is absence of resources to deal with the condition?

Statement of Interest

Graham and Elena Ewing (Dr) are Directors of Montague Healthcare a company devoted to the commercialisation of Virtual Scanning and hence to the diagnostic and therapeutic use of Virtual Scanning. They are co-authors of the book ‘Virtual Scanning – a new generation of healthcare – beyond biomedicine?’ ISBN 978-0-9556213-0-7 published by Montague Healthcare books.

Acknowledgments

We thank the many researchers who through their work have made this article possible.

Abstract

Patients with macrophagic myofasciitis (MMF) present with diffuse arthromyalgias, chronic fatigue, and cognitive disorder. Representative features of MMF-associated cognitive dysfunction include attentional dysfunction, dysexecutive syndrome, visual memory deficit and left ear extinction. Our study aims to reevaluate the neuropsychological profile of MMF. 105 unselected consecutive MMF patients were subjected to a neuropsychological battery of screen short term and long-term memory, executive functions, attentional abilities, instrumental functions and dichotic listening. From these results, patients were classified in four different groups: Subsymptomatic patients (n=41) with performance above pathological threshold (-1.65 SD) in all tests; Fronto-subcortical patients (n=31) who showed pathological results at executive functions and selective attention tests; Papezian patients (n=24) who showed pathological results in storage, recognition and consolidation functions for episodic verbal memory, in addition to fronto-subcortical dysfunction; and Extinction patients (n=9) who had a left ear extinction at dichotic listening test in association to fronto-subcortical and papezian dysfunction. In addition, inter-test analysis showed that patients with apparently normal cognitive functions (Subsymptomatic group) performed significantly worse to attention tests compared to others. In conclusion, our study shows that (i) most patients have specific cognitive deficits; (ii) all patients with cognitive deficit have impairment of executive functions and selective attention; (iii) patients without measurable cognitive deficits display significant weakness in attention; (iv) episodic memory impairment affects verbal, but not visual, memory; (v) none of the patients show an instrumental dysfunction.

Abstract

The autoimmune/inflammatory syndrome induced by adjuvants (ASIA) is a recently identified condition in which the exposure to an adjuvant leads to an aberrant autoimmune response. We aimed to summarize the results obtained from the ASIA syndrome registry up to December 2016, in a descriptive analysis of 300 cases of ASIA syndrome, with a focus on the adjuvants, the clinical manifestations, and the relationship with other autoimmune diseases. A Web-based registry, based on a multicenter international study, collected clinical and laboratory data in a form of a questionnaire applied to patients with ASIA syndrome. Experts in the disease validated all cases independently. A comparison study regarding type of adjuvants and differences in clinical and laboratory findings was performed. Three hundred patients were analyzed. The mean age at disease onset was 37 years, and the mean duration of time latency between adjuvant stimuli and development of autoimmune conditions was 16.8 months, ranging between 3 days to 5 years. Arthralgia, myalgia, and chronic fatigue were the most frequently reported symptoms. Eighty-nine percent of patients were also diagnosed with another defined rheumatic/autoimmune condition. The most frequent autoimmune disease related to ASIA syndrome was undifferentiated connective tissue disease (UCTD). ASIA syndrome is associated with a high incidence of UCTD and positive anti-nuclear antibodies (ANA) test. Clinical and laboratory features differ from the type of adjuvant used. These findings may contribute to an increased awareness of ASIA syndrome and help physicians to identify patients at a greater risk of autoimmune diseases following the exposure to vaccines and other adjuvants. The ASIA syndrome registry provides a useful tool to systematize this rare condition.

Adjuvants- and vaccines-induced autoimmunity: animal models.

Ruiz JT[1,2], Luján L[3], Blank M[2], Shoenfeld Y[4,5].

Author information

Abstract

The emergence of autoimmunity after vaccination has been described in many case reports and series. Everyday there is more evidence that this relationship is more than casual. In humans, adjuvants can induce non-specific constitutional, musculoskeletal or neurological clinical manifestations and in certain cases can lead to the appearance or acceleration of an autoimmune disease in a subject with genetic susceptibility. The fact that vaccines and adjuvants can trigger a pathogenic autoimmune response is corroborated by animal models. The use of animal models has enabled the study of the effects of application of adjuvants in a homogeneous population with certain genetic backgrounds. In some cases, adjuvants may trigger generalized autoimmune response, resulting in multiple auto-antibodies, but sometimes they can reproduce human autoimmune diseases including rheumatoid arthritis, systemic lupus erythematosus, Sjögren syndrome, autoimmune thyroiditis and antiphospholipid syndrome and may provide insights about the potential adverse effects of adjuvants. Likewise, they give information about the clinical, immunological and histologic characteristics of autoimmune diseases in many organs, especially secondary lymphoid tissue. Through the description of the physiopathological characteristics of autoimmune diseases reproduced in animal models, new treatment targets can be described and maybe in the future, we will be able to recognize some high-risk population in whom the avoidance of certain adjuvants can reduce the incidence of autoimmune diseases, which typically results in high morbidity and mortality in young people. Herein, we describe the main animal models that can reproduce human autoimmune diseases with emphasis in how they are similar to human conditions.

HPV vaccination syndrome. A questionnaire-based study.

Martínez-Lavín M[1], Martínez-Martínez LA[2], Reyes-Loyola P[2].

Author information

Abstract

Isolated cases and small series have described the development of complex regional pain syndrome, postural orthostatic tachycardia, and fibromyalgia after human papillomavirus (HPV) vaccination. These illnesses are difficult to diagnose and have overlapping clinical features. Small fiber neuropathy and dysautonomia may play a major role in the pathogenesis of these entities. We used the following validated questionnaires to appraise the chronic illness that might appear after HPV vaccination: The 2010 American College of Rheumatology Fibromyalgia Diagnostic Criteria, COMPASS 31 dysautonomia questionnaire, and S-LANSS neuropathic pain form. These questionnaires and a "present illness" survey were e-mailed to persons who had the onset of a chronic ailment soon after HPV vaccination. Forty-five filled questionnaires from individuals living in 13 different countries were collected in a month's period. Mean (±SD) age at vaccination time was 14 ± 5 years. Twenty-nine percent of the cases had immediate (within 24 h) post-vaccination illness onset. The most common presenting complaints were musculoskeletal pain (66%), fatigue (57%), headache (57%), dizziness/vertigo (43%), and paresthesias/allodynia (36%). Fifty-three percent of affected individuals fulfill the fibromyalgia criteria. COMPASS-31 score was 43 ± 21, implying advanced autonomic dysfunction. Eighty-three percent of the patients who had ongoing pain displayed S-LANSS values >12, suggesting a neuropathic component in their pain experience. After a mean period of 4.2 ± 2.5 years post-vaccination, 93% of patients continue to have incapacitating symptoms and remain unable to attend school or work. In conclusion, a disabling syndrome of chronic neuropathic pain, fatigue, and autonomic dysfunction may appear after HPV vaccination.

Chronic fatigue syndrome and fibromyalgia following immunization with the hepatitis B vaccine: another angle of the 'autoimmune (auto-inflammatory) syndrome induced by adjuvants' (ASIA).

Agmon-Levin N[1], Zafrir Y, Kivity S, Balofsky A, Amital H, Shoenfeld Y.

Author information

Abstract

The objectives of this study were to gather information regarding demographic and clinical characteristics of patients diagnosed with either fibromyalgia (FM) or chronic fatigue (CFS) following hepatitis B vaccination (HBVv) and furthermore to apply the recently suggested criteria of autoimmune (auto-inflammatory) syndromes induced by adjuvants (ASIA), in the aim of identifying common characteristics that may suggest an association between fibromyalgia, chronic fatigue and HBV vaccination. Medical records of 19 patients with CFS and/or fibromyalgia following HBVv immunization were analyzed. All of which were immunized during 1990-2008 in different centers in the USA. All medical records were evaluated for demographics, medical history, the number of vaccine doses, as well as immediate and long term post-immunization adverse events and clinical manifestations. In addition, available blood tests, imaging results, treatments and outcomes were analyzed. ASIA criteria were applied to all patients. The mean age of patients was 28.6 ± 11 years, of which 68.4 % were females. 21.05 % had either personal or familial background of autoimmune disease. The mean latency period from the last dose of HBVv to onset of symptoms was 38.6 ± 79.4 days, ranging from days to a year. Eight (42.1 %) patients continued with the immunization program despite experiencing adverse events. Manifestations that were commonly reported included neurological manifestations (84.2 %), musculoskeletal (78.9 %), psychiatric (63.1 %), fatigue (63.1 %), gastrointestinal complains (58 %) and mucocutaneous manifestations (36.8 %). Autoantibodies were detected in 71 % of patients tested. All patients fulfilled the ASIA criteria. This study suggests that in some cases CFS and FM can be temporally related to immunization, as part of ASIA syndrome. The appearance of adverse event during immunization, the presence of autoimmune susceptibility and higher titers of autoantibodies all can be suggested as risk factors. ASIA criteria were fulfilled in all patients eluding the plausible link between ASIA and CFS/FM.

Evolution of multiple sclerosis in France since the beginning of hepatitis B vaccination.

Le Houézec D[1].

Author information

Abstract

Since the implementation of the mass vaccination campaign against hepatitis B in France, the appearance of multiple sclerosis, sometimes occurring in the aftermath of vaccinations, led to the publication of epidemiological international studies. This was also justified by the sharp increase in the annual incidence of multiple sclerosis reported to the French health insurance in the mid-1990s. Almost 20 years later, a retrospective reflection can be sketched from these official data and also from the national pharmacovigilance agency. Statistical data from these latter sources seem to show a significant correlation between the number of hepatitis B vaccinations performed and the declaration to the pharmacovigilance of multiple sclerosis occurring between 1 and 2 years later. The application of the Hill's criteria to these data indicates that the correlation between hepatitis B vaccine and multiple sclerosis may be causal.

Postural Orthostatic Tachycardia With Chronic Fatigue After HPV Vaccination as Part of the "Autoimmune/Auto-inflammatory Syndrome Induced by Adjuvants": Case Report and Literature Review

Lucija Tomljenovic, PhD[1,2], Serena Colafrancesco, MD[1,3], Carlo Perricone, MD[1,3], and Yehuda Shoenfeld, MD, FRCP (Hon), MaACR[1,4]

Abstract

We report the case of a 14-year-old girl who developed postural orthostatic tachycardia syndrome (POTS) with chronic fatigue 2 months following Gardasil vaccination. The patient suffered from persistent headaches, dizziness, recurrent syncope, poor motor coordination, weakness, fatigue, myalgias, numbness, tachycardia, dyspnea, visual disturbances, phonophobia, cognitive impairment, insomnia, gastrointestinal disturbances, and a weight loss of 20 pounds. The psychiatric evaluation ruled out the possibility that her symptoms were psychogenic or related to anxiety disorders. Furthermore, the patient tested positive for ANA (1:1280), lupus anticoagulant, and antiphospholipid. On clinical examination she presented livedo reticularis and was diagnosed with Raynaud's syndrome. This case fulfills the criteria for the autoimmune/auto-inflammatory syndrome induced by adjuvants (ASIA). Because human papillomavirus vaccination is universally recommended to teenagers and because POTS frequently results in long-term disabilities (as was the case in our patient), a thorough follow-up of patients who present with relevant complaints after vaccination is strongly recommended.

Introduction

Postural orthostatic tachycardia syndrome (POTS) is a heterogeneous disorder of the autonomic nervous system in which a change from the supine position to an upright position causes an abnormally large increase in heart rate or tachycardia (30 bpm within 10 minutes of standing or head-up tilt).[1] The tachycardic response in POTS is frequently accompanied by a decrease in blood flow to the brain and hence a spectrum of symptoms associated with cerebral hypoperfusion (Table 1).[1-3] Due to the wide heterogeneity of symptoms and its frequent co-occurrence with other systemic autoimmune diseases, POTS is difficult to diagnose. Moreover, because many of POTS-related symptoms are also observed in chronic anxiety and panic disorders, POTS is frequently underdiagnosed and misdiagnosed.[2]

POTS predominantly affects women of the childbearing age with a 5:1 female–male ratio.[2] The estimated prevalence of POTS is at least 170/100 000. This estimate was based on the finding that 40% of patients with chronic fatigue syndrome (CFS) also suffer from POTS.[4] Indeed, CFS is a frequent and major comorbidity in POTS.[5,6] The 2 conditions frequently appear together, and research shows that there is a clinically identifiable subgroup of patients with CFS and orthostatic intolerance that differs from control subjects and from those with CFS without orthostatic intolerance.[4] In agreement with these observations, Okamoto et al[7] recently found that the majority of patients with POTS also fulfilled the criteria for CFS and that severe fatigue and CFS-defining

Constipation	–
Abdominal pain	+
Bladder symptoms	–
Other associated symptoms	
Fatigue	+
Sleep disturbances	+
Migraines	+
Neuropathic type pain	+
Cognitive disturbances	+
Flu-like symptoms	+

symptoms were also common in POTS patients who did not meet all the criteria for CFS. Such typical CFS symptoms that are overrepresented in POTS patients include migraine, incapacitating fatigue, fibromyalgia, unrefreshing sleep, and impaired memory or concentration. Flu-like symptoms associated with CFS such as joint pains, tender lymph nodes, and sore throat are also present in POTS albeit with lesser prevalence.[7] These and other similar observations indicate that POTS with CFS is not a separate clinical entity entirely distinct from POTS but rather a more severe form of this condition.[7,8] Much like POTS, CFS affects predominantly women and can be severely disabling, profoundly impairing patients' ability to function on a daily basis.[6,9]

Genetic as well as nongenetic factors such as trauma, bacterial or viral infection, and pregnancy may predispose to POTS.[1] In addition, it is becoming increasingly recognized that POTS and CFS can also be triggered by various medications (ie, antihypertensive drugs, antipsychotics)[1] and vaccines.[10-15] Herein we describe a case of a 14-year-old girl who presented with POTS/CFS of an autoimmune origin approximately 2 months after receiving her second injection of the quadrivalent human papillomavirus (qHPV) vaccine Gardasil.

Case Report

A 14-year-old previously healthy girl presented with flu-like symptoms, sore throat, low-grade fever, fatigue, swollen glands, and intense headaches in February 2009, approximately 2 months after her second qHPV vaccine injection. Over the course of 1 week, the headache intensified and the patient further presented with photophobia, phonophobia, altered sense of taste, diminished appetite, gait disturbances, leg weakness, and inability to walk without assistance. By March 2009, her condition worsened and she quit regular school attendance due to progressively disabling symptoms. At that time she developed syncope and incapacitating chronic fatigue. Although the patient subsequently resumed attending school (by the end of 2009), her attendance was limited to 2 hours per day due to fatigue, diminished ability to focus, weakness, and severely impaired balance and coordination. She attended school in a wheel-chair and was exhausted after the 2-hour period. Her illness continue to progress, and by the end of 2010, she had the following symptoms: persistent incapacitating headaches, dizziness, recurrent syncope, lower extremity weakness, poor motor coordination, fatigue, neck pain, joint pains, numbness in the legs, blurred vision, photophobia, phonophobia, cognitive impairment, insomnia, tachycardia, dyspnea, impaired thermoregulation, cold extremities, blush discoloration of toes, excessive hair loss, gastrointestinal (GI) disturbances, altered sense of taste, diminished appetite, and weight loss (20 pounds within 3 months of symptoms onset). The psychiatric evaluation in September 2009 ruled out the possibility that the patient's symptom were of psychosomatic origin, and the subsequent evaluation in 2010 found no evident signs of panic and anxiety disorders.

Serological evaluations revealed a number of abnormalities, including an elevated ANA at 1:1280, a positive lupus anticoagulant, and a weakly positive antiphospholipid of 7.3 in October 2009. On clinical examination, the patient presented livedo reticularis. She was then diagnosed with an undifferentiated connective tissue disease and Raynaud's syndrome. Serology results for Epstein–Barr virus, Lyme, Babesia, and Ehrlichia were negative. Titers to *Streptococcus pneumoniae* indicated previous exposure but were however within a normal range, thus ruling out recent exposure.

Over the course of her illness, the patient experienced a complete loss of consciousness with syncope approximately 12 times. These problems were never present prior to the onset of the illness in February 2009. On further testing, the patient was diagnosed with orthostatic intolerance. In

Table 2. The Suggested Criteria of ASIA[29,30] in the Current Case of Post-HPV Vaccine POTS/CFS.

Major Criteria	Present in Current Case
1. Exposure to an external stimuli (infection, vaccine, and/or immune adjuvants) prior to clinical manifestations	+
2. The appearance of "typical" clinical manifestations	
Myalgia, muscle weakness	+
Arthralgia and/joint pain	+
Chronic fatigue, unrefreshing sleep or sleep disturbances	+
Neurological manifestations	+
Cognitive impairment, memory loss	+
Pyrexia	−
3. Removal of inciting agent induces improvement	NA
4. Typical biopsy of involved organs	Not assessed
Minor Criteria	**Present in Current Case**
1. The appearance of autoantibodies	+
2. Other clinical manifestations (gastrointestinal disturbances, livedo reticularis)	+
3. Specific HLA (eg, HLA DRB1, HLA DQB1)	Not assessed
4. Evolvement of an autoimmune disease (undifferentiated connective tissue disease/ Raynaud's, probable secondary antiphospholipid syndrome)	+

particular, on the standing test the patient's lowest heart rate supine was 47 bpm with a blood pressure 103/56 mm Hg. On standing, the patient's heart rate increased immediately to 82 bpm and continued to increase to a maximum of 98 bpm after 9 minutes. According to the electrophysiologist, the patient's recurrent syncope was thus consistent with neurally mediated hypotension, and in December 2009, she was finally diagnosed with vasovagal syncope and associated postural orthostatic tachycardia syndrome. In addition, her illness met the criteria for CSF given her persisting fatigue of over 6 months, new-onset disabling headaches, postexertional worsening of the fatigue, myalgias, cognitive dysfunction, and unrefreshing sleep (Table 1). The patient's relevant medical history includes a family history of Raynaud's (patient's mother) and a personal history of headaches, dizziness, photophobia, and phonophobia in 2007, all of which however resolved completely in the same year.

Discussion

Autoimmune Origin of POTS and CFS

Herein we described a case that clearly fulfilled the criteria for POTS/CFS (Table 1) secondary to qHPV vaccine booster injection. An autoimmune mechanism has been suggested as a causal mechanism in both POTS and CFS due to frequent findings of autoantibodies (including ANA) in POTS/CFS patients.[16,17] Other reported abnormalities in CFS also point to an underlying autoimmune mechanism (ie, increased levels of pro-inflammatory cytokines interleukin-1, tumor necrosis factor-α, and increased levels of nuclear factor-κB).[18] It is estimated that up to 60% of CFS patients suffer from autoimmune responses[18] and that both POTS and CFS frequently co-occur with systemic autoimmune disorders including multiple sclerosis,[19] Sjorgen's syndrome,[20] lupus,[1,21] and Raynaud's.[22] Similarly, our case was diagnosed with Raynaud's, CFS, and neurally mediated hypotension or more specifically, POTS.

Our patient's symptoms began manifesting approximately 2 months following vaccination. An interval of 6 weeks between exposure and outcome is often used as evidence of a plausible causal association; however, immune and autoimmune diseases are chronic diseases that more often than not have a long incubation time.[23] For example, it was reported by Arbuckle et al that systemic lupus erythematosus (SLE) evolves slowly and progressively over many years and only when enough autoantibodies are present.[24] In particular, autoantibodies were found in 88% of SLE patients up to 9.4 years before the clinical diagnosis of the syndrome (mean = 3.3 years).[24] Thus, long-term persistence of elevated titers of autoantibodies was necessary for the emergence of clinically overt signs and symptoms for the diagnosis of SLE. Notably, the accumulation of autoantibodies occurred while patients were still asymptomatic.

Similarly, postvaccination adverse immune phenomena can have long latency periods (ie, month to years following immunization).[25-27] As early as 1982, compelling evidence from epidemiological, clinical, and animal research has emerged to show that autoimmune neuropathies can occur 4 to 10 months following vaccination.[28] In such cases the disease would first manifest with vague symptoms (ie, arthralgia, myalgia, paraesthesia, weakness—note also that these are typical ASIA symptoms; Table 2), which were frequently deemed as insignificant and thus ignored. These symptoms, otherwise known as "bridging symptoms" and consistent with a mild subclinical disease, would progress slowly and insidiously until exposure to a secondary immune stimulus. The latter would then trigger the rapid and acute clinical

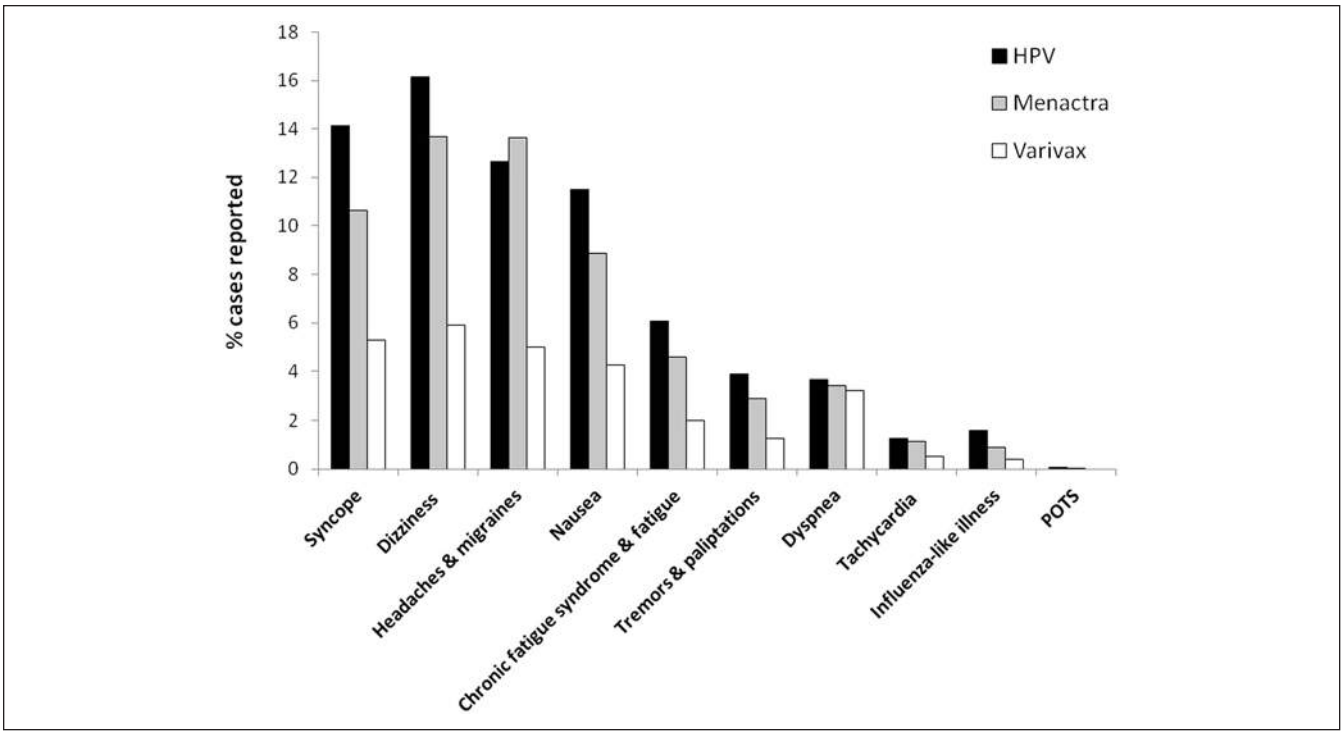

Figure 1. Number of adverse event reports related to POTS/CFS following HPV, Menactra meningococcal polysaccharide diphtheria toxoid conjugate, and Varivax Varicella vaccines in the US Vaccine Adverse Event Reporting System (VAERS) as of February 13, 2013. The VAERS database[33] was searched using the following criteria: (1) Symptoms: syncope (general, exertional, postural); headaches (including migraines); nausea; chronic fatigue syndrome (including general fatigue); tremors and palpitations; dyspnea (general, exertional, at rest); tachycardia (including tachyarrhythmia, tachycardia paroxysomal, heart rate abnormal, heart rate increased, heart rate irregular); influenza-like illness (including viremia, viral infection); POTS; (2) Vaccine products: HPV, HPV2 (human papilloma virus bivalent), HPV4 (human papilloma virus types 6, 11, 16,1 8); MNQ (Meningococcal vaccine Menactra); Varcel (Varivax-Varicella virus live); (3) Gender (all genders); (4) Age (6 to 29 years; target age group for HPV, Menactra and Varivax vaccines); (5) Territory (the United States); (6) Date vaccinated (2007-2013; HPV vaccine postlicensure period).[34] Adverse events related to a particular symptom are reported as percentages of the total number of events reported for the particular vaccine (ie, 14% syncope refers to the 2354 reports of syncope out of a total of 16 644 adverse events associated with the HPV vaccine; the total number of adverse events reported for Varivax and Menactra was 9136 and 8790, respectively).

manifestation of the disease.[28] In other words, it was the secondary anamnestic response that would bring about the acute overt manifestation of an already present subclinical long-term persisting disease.

Consistent with these observations, we recently described several cases of autoimmunity (systemic lupus) following Gardasil where the nonspecific ASIA-related manifestations eventually progressed over time to a full-blown immune disease following subsequent vaccine reexposure.[31] Moreover, in all of our cases, several common features were observed, namely, a personal or familial susceptibility to autoimmunity and an adverse response to a prior dose of the vaccine, both of which were associated with a higher risk of postvaccination full-blown autoimmunity.[31]

POTS and Vaccinations

Ours is the seventh case of POTS associated with the qHPV vaccine Gardasil reported in the literature. In addition, POTS following administration of the novel H1N1 influenza vaccine was reported recently.[13] Recently, Blitshteyn[12] reported six cases of POTS following HPV vaccination. In this case series, all six previously healthy young women (aged 12 to 22 years) developed symptoms of POTS within 6 days to 2 months after vaccination with the Gardasil HPV vaccine. Of further relevance to our case, two out of six cases reported by Blitshteyn also showed a positive ANA and, in all six cases the symptoms were disabling. In particular, three of the patients were not capable of attending school full time and one of them became wheel-chair bound like the patient described in our report. The course of POTS following HPV vaccination was similar in all six patients, with all of them improving in 2 to 3 years' time frame with the use of standard pharmacotherapy for POTS. It is possible as emphasized by Blitshteyn[12] that some patients with POTS are simply undiagnosed or misdiagnosed with anxiety and panic-related disorders, which leads to underreporting and a paucity of data on the incidence of POTS and other autonomic system disorders following vaccination. The analysis of the US VAERS database substantiates this concern. In particular, although the majority of POTS-related symptoms were reported in 4% to 16% of HPV vaccine recipients, POTS was only reported in 0.07% of cases (Figure 1). The highest number of both POTS- and CFS-related symptom reports was associated

with HPV vaccines when compared with 2 other vaccines (Menactra and Varivax), routinely given to adolescents in the United States. On average, the number of VAERS reports related to POTS/CFS symptoms was 3 to 5 times greater for the HPV compared with the Varivax vaccine. A relatively high percentage of POTS/CFS symptom reports was also associated with the Menactra vaccine. If these symptoms were psychogenic and not related to a specific vaccine but rather a reaction to the injection procedure itself, one would expect a more even distribution of reports with different vaccines. In particular, the percentage of POTS/CFS reports for Varivax should be more or less the same as for Menactra especially considering the fact that the total number of VAERS reports associated with these 2 vaccines was roughly the same (9136 and 8790, respectively). As shown in Figure 1, this is not the case. Consistent with our findings, Slade et al[32] found a disproportional reporting of syncope following HPV compared with other vaccines in their 2009 postlicensure analysis of adverse events reported to VAERS and published in JAMA. We are in further agreement with Slade et al[32] who also noted that although VAERS shares inherent limitations of all passive surveillance systems, it is national in scope and can thus provide important signals that may require further attention. Indeed, because both POTS and CFS are frequently severely disabling,[1,6,9,10,13,15] a more thorough follow-up of patients who present with relevant complaints postvaccination seems warranted in order to determine the true incidence of these syndromes with particular vaccines.

Another possible reason for the frequent misdiagnosis of POTS is that patients with this syndrome typically present with complaints that partially overlap with those seen in panic disorders or chronic anxiety.[2] Notably, such symptoms (syncope, hyperventilation, limb jerking, numbness or tingling, palpitations, and tremors) appear to be among the most frequently reported adverse reactions following vaccination with HPV vaccines and may be mistakenly labeled as "psychogenic events."[35] From our patient's medical history, it is evident however that the post-qHPV vaccination phenomena were neither temporary nor psychogenic. Indeed, the psychiatrist's evaluation specifically excluded the latter in addition of finding no relevant signs of anxiety or panic disorders. The highly positive ANA further excludes a psychosomatic origin of the patient's illness; rather, it suggest an immune-/auto-immune-mediated underlying pathology.

Although in our case the patient had a previous history of relevant symptoms (headaches, dizziness, photophobia, and phonophobia) 2 years prior to qHPV vaccination, all of these symptoms resolved in the same year and did not cause long-term disability of the patient. Indeed, at the time of first vaccination the patient was in good general health. Moreover, during the course of her illness, the patient experienced a wide spectrum of new-onset adverse conditions, including recurrent episodes of syncope with complete loss of consciousness, disabling fatigue, neck pain, joint pains, numbness in the legs, cognitive disturbances, blurred vision, unrefreshing sleep, tachycardia, dyspnea, impaired thermoregulation, cold extremities, blush discoloration of toes, excessive hair loss, GI disturbances, diminished appetite, altered sense of taste, and significant weight loss. She also tested positive for ANA, lupus anticoagulant, and antiphospholipid and was subsequently diagnosed with undifferentiated connective tissue disease/Raynaud's. Notably, none of these manifestations were present prior to the onset of her illness in February 2009 following Gardasil vaccination, indicating that the vaccine may have been the triggering, or at the very least, the exacerbating factor.

Although a viral illness cannot be completely excluded as the primary trigger of POTS/CFS in our case, it should be noted that symptoms mimicking viral illness (commonly referred to as flu-like symptoms) are in fact one of the well-recognized symptom categories in CFS.[10,36] Moreover, both flu-like symptoms and CFS are associated with the use of certain vaccines, and more specifically, aluminum and other vaccine adjuvants.[14,15,37] Indeed, because vaccines induce an immune response similarly to infections, they may also just like infections trigger autoimmune diseases.[38] However, unlike infectious agents, vaccines frequently contain adjuvants that further enhance their immune stimulation, above the levels of natural infections.[39] These observations suggest that vaccines may provoke more exaggerated, anarchic immune responses than infections. The latter point is specially relevant in view of the fact that vaccines (including HPV) are typically repeatedly administered over relatively short periods of times (ie, weeks or months). Moreover, vaccines have been reported to precede CFS mainly following exposure to multiple vaccinations and/or as an adverse response to the vaccine adjuvant.[14,15,39,40]

POTS, CFS, and the ASIA Syndrome

It is of further relevance to note that the safety trials for Gardasil (which is an aluminum-adjuvanted vaccine) did not include a true inactive placebo but rather an aluminum-adjuvant-containing placebo,[41] despite much data showing that aluminum in vaccine-relevant exposures can be toxic to humans.[42,43] In the last decade, studies on animal models have repeatedly demonstrated the ability of aluminum adjuvants to inflict immune-mediated diseases by themselves.[44,45] This research culminated in delineation of ASIA (autoimmune/inflammatory syndrome induced by adjuvants), which encompasses several medical conditions with similar set of signs and symptoms and a common exposure to an immune adjuvant.[10,29] Shoenfeld and colleagues proposed 4 major and 4 minor criteria for ASIA (Table 2), and in order to diagnose ASIA, fulfillment of either 2 major or 1 major and 2 minor criteria is required.[29] The criteria for ASIA enable the inclusion of patients with well-defined autoimmune diseases (ie, multiple sclerosis, lupus) as well as those with ill-defined and nonspecific yet clinically relevant conditions (ie, myalgia, chronic fatigue, and cognitive disturbances) under the spectrum of vaccine adjuvant-associated conditions.[30] The

inclusion of the latter category of manifestations under ASIA is of special importance as these nonspecific manifestations are all too easily ignored or disregarded as irrelevant and nonvaccine related not only by patients and physicians but also by scientists involved in design of vaccine trials.[46,47] Nonetheless, many ill-defined medical conditions that fall under the ASIA spectrum are frequently disabling and thus of significant clinical relevance. For example, CFS and cognitive dysfunction associated with the aluminum vaccine adjuvant-induced macrophagic myofasciitis (MMF) syndrome are disabling in 87% and 53% of cases, respectively,[9] and impair both professional activities as well as numerous aspects of daily life.[9,42] Similarly in our case, the patient was unable to attend regular school due to progressive and disabling POTS/CFS symptoms. In addition, some of the nonspecific ASIA manifestations have the potential to progress over time to a full-blown autoimmune disease, especially following subsequent vaccine re-exposure.[31] Of note, our patient fulfilled the first 2 major criteria for ASIA (due to a prior exposure to the HPV vaccine and the obvious appearance of "typical" manifestations) as well as 3 minor criteria, owing to the positive ANA, lupus anticoagulant, and antiphospholipid and the concurrent diagnosis of Raynaud's (Table 2).

In years following licensure, numerous case reports of serious adverse reactions of the autoimmune origin associated with the qHPV vaccine Gardasil have raised concerns about the safety of the vaccine.[12,31,48-52] Postlicensure data from vaccine safety surveillance databases worldwide appear to substantiate these concerns. For example, in the United States, compared with all other vaccines Gardasil alone is associated with >60% of all serious adverse reactions (including 63.8% of all deaths and 81.2% cases of permanent disability) in females younger than 30 years of age.[34] These observations suggest that HPV vaccine risks may not have been fully identified during prelicensure trials.[34,41,53] The unusual frequency of adverse reactions following HPV vaccination cannot solely attributed to the aluminum adjuvant, as many other vaccines also contain aluminum (ie, tetanus, diphtheria, etc) but are not associated with as many adverse reactions. However, it is the aluminum that evokes the enhanced immune reaction necessary for inducing the production of the elevated titers of antibodies. The antigen on its own is not capable of evoking this strong immune response. Because of this, any adverse effect arising from the antigen (or other constituents in the vaccine) is ultimately linked to the action of the adjuvant. For example, Zivkovic et al[54] showed that induction of the antiphospholipid syndrome (APS) syndrome and associated decreased fecundity by tetanus toxoid (TTd) hyperimmunization in C57BL/6 mice critically depends on the aluminum adjuvant. In particular, Zivkovic et al[54] investigated reproductive pathology induced in C57BL/6 mice by TTd hyperimmunization using a combination of different pretreatments (complete Freund's adjuvant or glycerol) and adjuvants (aluminum-hydrogel or glycerol). A decrease in fecundity was recorded in only C57BL/6 mice immunized with aluminum-hydrogel adjuvant, irrespective of the kind of applied pretreatment.

In conclusion, herein we described a case of disabling CFS/POTS secondary to qHPV Gardasil vaccination with symptom onset at 2 months following the second vaccine booster. With the concurrent detection of elevated ANA, lupus anticoagulant, antiphospholipid, and subsequent diagnosis of Raynaud's, this case fully meets the criteria for the recently identified ASIA syndrome (Table 2). Moreover, the case presented here is consistent with other literature supporting an immune-mediated etiology of POTS and CFS.[1,12,13,15-17] To the best of our knowledge, this is the second case of post-HPV vaccine associated POTS described in the literature to date. Due to the wide heterogeneity of symptoms and its frequent co-occurrence with other systemic autoimmune diseases, POTS is difficult to diagnose and hence many cases remain unreported. The relatively high prevalence of POTS/CFS-related symptoms in young women vaccinated with HPV vaccines (Figure 1) should alert physicians to a closer monitoring of post-HPV-related manifestations fitting the POTS/CFS criteria. We also recommend further studies to ascertain whether or not the association between HPV vaccination and POTS is causal.

Authors' Note

An informed consent has been received from the patient to present her case.

Declaration of Conflicting Interests

The author(s) declared the following potential conflicts of interest with respect to the research, authorship, and/or publication of this article: Y. Shoenfeld is currently providing expert testimony in cases involving adverse reactions to the HPV and other vaccines in the US National Vaccine Injury Compensation Program (including this case). LT, SC, and CP declared no potential conflicts of interest.

Funding

The author(s) disclosed receipt of the following financial support: LT receives research funding from the Dwoskin Family Foundation. No specific funding was received for the publication of this article.

Abstract

In 2011 a new syndrome termed 'ASIA Autoimmune/Inflammatory Syndrome Induced by Adjuvants' was defined pointing to summarize for the first time the spectrum of immune-mediated diseases triggered by an adjuvant stimulus such as chronic exposure to silicone, tetramethylpentadecane, pristane, aluminum and other adjuvants, as well as infectious components, that also may have an adjuvant effect. All these environmental factors have been found to induce autoimmunity by themselves both in animal models and in humans: for instance, silicone was associated with siliconosis, aluminum hydroxide with post-vaccination phenomena and macrophagic myofasciitis syndrome. Several mechanisms have been hypothesized to be involved in the onset of adjuvant-induced autoimmunity; a genetic favorable background plays a key role in the appearance on such vaccine-related diseases and also justifies the rarity of these phenomena. This paper will focus on protean facets which are part of ASIA, focusing on the roles and mechanisms of action of different adjuvants which lead to the autoimmune/inflammatory response. The data herein illustrate the critical role of environmental factors in the induction of autoimmunity. Indeed, it is the interplay of genetic susceptibility and environment that is the major player for the initiation of breach of tolerance.

Autoimmune (auto-inflammatory) syndrome induced by adjuvants (ASIA)--animal models as a proof of concept.

Cruz-Tapias P[1], Agmon-Levin N, Israeli E, Anaya JM, Shoenfeld Y.

Author information

Abstract

ASIA syndrome, "Autoimmune (Auto-inflammatory) Syndromes Induced by Adjuvants" includes at least four conditions which share a similar complex of signs and symptoms and have been defined by hyperactive immune responses: siliconosis, macrophagic myofasciitis syndrome, Gulf war syndrome and post-vaccination phenomena. Exposure to adjuvants has been documented in these four medical conditions, suggesting that the common denominator to these syndromes is a trigger entailing adjuvant activity. An important role of animal models in proving the ASIA concept has been established. Experimentally animal models of autoimmune diseases induced by adjuvants are currently widely used to understand the mechanisms and etiology and pathogenesis of these diseases and might thus promote the development of new diagnostic, predictive and therapeutic methods. In the current review we wish to unveil the variety of ASIA animal models associated with systemic and organ specific autoimmune diseases induced by adjuvants. We included in this review animal models for rheumatoid arthritis-like disease, for systemic lupus erythematosus-like disease, autoimmune thyroid disease-like disease, antiphospholipid syndrome, myocarditis and others. All these models support the concept of ASIA, as the Autoimmune (Auto-inflammatory) Syndrome Induced by Adjuvants.

Summary

Go to:

Aluminium oxyhydroxide (alum), a nano-crystaline compound forming agglomerates, has been introduced in vaccine for its immunologic adjuvant effect in 1927. Alum is the most commonly used adjuvant in human and veterinary vaccines but mechanisms by which it stimulates immune responses remains incompletely understood. Although generally well tolerated, alum may occasionally cause disabling health problems in presumably susceptible individuals. A small proportion of vaccinated people present with delayed onset of diffuse myalgia, chronic fatigue and cognitive dysfunction, and exhibit very long-term persistence of alum-loaded macrophages at site of previous intra-muscular (i.m.) immunization, forming a granulomatous lesion called macrophagic myofasciitis (MMF). Clinical symptoms associated with MMF are paradigmatic of the recently delineated “autoimmune/inflammatory syndrome induced by adjuvants” (ASIA). The stereotyped cognitive dysfunction is reminiscent of cognitive deficits described in foundry workers exposed to inhaled Al particles. Alum safety concerns will largely depend on whether the compound remains localized at site of injection or may diffuse and accumulate in distant organs. Animal experiments indicate that biopersistent nanomaterials taken-up by monocytes-lineage cells in tissues, e.g. fluorescent alum surrogates, can first translocate to draining lymph nodes, and thereafter circulate in blood within phagocytes and reach the spleen, and, eventually, slowly accumulate in brain.

Introduction

Go to:

In 1998, a consortium of French myopathologists described an emerging condition of unknown cause characterized by a pathognomonic lesion at muscle biopsy we called macrophagic myofasciitis (MMF).[1] MMF was detected in middle-aged adult patients with diffuse myalgias and fatigue.[1] Macrophages was the major cell type in the lesion, and enclosed agglomerates of nanocrystals in their cytoplasm.[1] Subsequently, these inclusions proved to be a key finding as they were constantly present at electron microscopy, and conspicuously contained aluminium as shown by ionic or X-ray microanalysis.[2] MMF was typically detected in the deltoid muscle, and could be differentiated both clinically and pathologically from Whipple’s disease and other infectious histiocytoses, and from diffuse dysimmune fasciitis and panniculitis. [3] The crystalline rather than amorphous ultrastructural appearance of the inclusions was suggestive of aluminium hydroxide. Patients had normal renal function and had no peculiar exposure to aluminium other than previous immunization against hepatitis B (HBV), hepatitis A (HAV) or tetanus toxoid (TT) vaccines (100%), thus strongly suggesting that MMF inclusions correspond to aluminium oxyhydroxide (alum), an adjuvant incorporated in these vaccines to boost immunologic responses.[2] It is now clear that rapid emergence of MMF in France resulted from the specific combination of 3 factors : (1) replacement of the subcutaneous route by the i.m. route of vaccination in the early 1990s; (2) widespread extension of HBV primovaccination to the French adult population in the same time; and (3) the choice of the deltoid muscle (also used for i.m. vaccination) for routine muscle biopsy in France whereas biceps brachialis and quadriceps femoris muscles are preferred in most other countries. MMF lesion is now universally recognized to assess long-term persistence of alum at site of previous intramuscular (i.m.) immunization.[4] However, alum has been generally

considered as safe on the basis of short-term surveys, and exact significance of longstanding MMF detection in a given patient remains uncertain because of (i) apparently "poorly specific" clinical manifestations, which of course does not mean non-disabling ones, and (ii) lack of self-evident link between persistence of alum agglomerates into macrophages at site of immunization and delayed onset of systemic and neurologic manifestations. Formal delineation of "autoimmune/inflammatory syndrome induced by adjuvants" (ASIA),[5] and novel insights into the biodistribution of slowly biodegradable particles taken-up by monocyte-lineage cells in peripheral tissues provide settlement for a better understanding of this rare adverse effect of alum.

MMF histopathology

Go to:

Deltoid muscle biopsy findings are stereotyped,[1–4] consisting of focal infiltration of the epimysium, perimysium and perifascicular endomysium by well-circumscribed and cohesive sheets of large mononuleated cells of the monocyte and macrophage lineage, usually intermingled with a minor lymphocytic population. The maximum observed section size of the lesion is 1cm. Aluminium salts are positively stained by hematoxylin and, consistently, the cytoplasm of macrophages is basophilic (dark blue) on hematoxylin-eosin stained cryostat sections. Probably due to specific chemical reactions, this is not observed on formalin fixed material in which macrophages exhibit a finely granular grey/beige content. In both cryostat and paraffin sections, macrophages are strongly periodic Acid Schiff $(PAS)^+$. They express CD68 and major histocompatibility complex (MHC) class 1 and MHC class 2 antigens. $CD3^+$ T-cells, mainly $CD8^+$, forming perivascular cuffs are constantly found. Occasional $CD19^+$ B cells, rarely forming lymphoid follicles, and $CD138^+$ plasma cells may be detected. Giant multinucleated cells are not detected except when another foreign material, e.g. coton wool, is present. In rare instances (about 1%) the granuloma may be encircled by thick fibrotic tissue and centered by a large necrotic area, forming a lesion reminiscent of a rheumatoid nodule. Myofibers remote from the infiltrate are typically intact, but MMF may be occasionnaly associated with typical dermatomyositis or autoimmine necrotizing myopathy. At electron microscopy, macrophages appear heavily loaded with submicron/micron-sized agglomerates of spiculated osmiophilic structures surrounded by discontinuous lysosomal membranes. In routine, inclusions can be visualized by the Morin stain for aluminium. Micro-organisms are not detected by appropriate stainings or electron microscopy.

Similar MMF lesions can be detected in the quadriceps muscle in babies and children because this muscle is used for i.m. vaccine administration in young individuals. MMF can be experimentally reproduced by i.m. vaccination in mice, rats and monkeys,[2,6,7] progressively shrinking with time.[6] It is, therefore, important to determine if the MMF lesion is unusually persistent in biopsied patients by precisely recapitulating history of previous vaccinations. In practice we consider MMF to be so when the time elapsed from last vaccine shot to MMF detection is >18 months. This point is particularly important in small children who receive numerous alum-containing vaccine shots in the first year of life, increasing risk of chance associations between MMF lesions and unrelated conditions, e.g. congenital myopathies and muscular dystrophies.[8] The risk also exists in adults but accounts for no more than 5–10% of MMF^+ biopsies, including fully asymptomatic patients and patients investigated for hereditary disorders.

In contrast to i.m. injections, alum-containing vaccines administered by the s.c. route may elicit chronic lesions that are somewhat different from MMF, so-called cutaneous pseudo-lymphoma, associated with a rim of alum-containing macrophages.[9]

From MMF-associated syndrome to ASIA

Go to:

According to the patient association, about 1000 patients with documented MMF have been identified in France. Occasional cases have been reported in many other countries.[8,10–15] The structure of symptoms was strikingly similar in independent cohorts of French adult patients.[4] We recently reviewed the files of 457 adult MMF patients collected from 1994 to 2011 in our centre. Patients were either investigated and biopsied (n=270) at the Neuromuscular Centre of Créteil (Neuromuscular Reference Centre Garches-Necker-Mondor-Hendaye), or were referred for follow-up or complementary investigation after MMF detection in other French hospitals by one of the myopathologists that had described the lesion (n=187). Most patients were females (70%) and at the middle age at time of biopsy (median 45 years, range 12–83). They had received 1 to 17 i.m. alum-containing vaccine administrations (mean 5.3) in the 10 years before MMF detection, and these included HBV vaccination in 85%. Patients mainly complained of chronic diffuse myalgias >6mois (89%) with or without arthralgias, disabling chronique fatigue >6 months (77%), overt cognitive alterations affecting memory and attention (51%), and dyspnea 50%. As previously reported, onset of these clinical symptoms was always posterior to, and delayed from, immunization, median time elapsed from last vaccine administration being 7 months (range 0.5–84) for initial systemic symptoms, and 11 months (range 0–72) for first myalgia.[4] Time elapsed from last vaccine administration to biopsy was 65 months (range 3–219). Compared to our previous reports, this delay has progressively increased (36 months in the initial series of 2001, 53 months in series of 2003), [4] indicating that MMF patients are chronically diseased and, though mainly vaccinated in the late nineties or early 2000', frequently looked for diagnosis long after onset of symptoms.

Myalgias and fatigue may not be synchronous. Myalgia may follow an exercise of unusual intensity and often begin in lower limbs,[4] and almost never at site of previous vaccine injection. Myalgia progressively extend upward to affect paravertebral muscles and become diffuse at time of biopsy.[4] Muscle weakness is rare. Myopathic electromyogram and CK elevation are found in less than one half of patients. Some fibromyalgic tender points are detected in a minority of patients, but the 1990 ACR criteria for fibromyalgia are rarely fulfilled.[4] Interestingly, ^{67}Gallium scintigrams has shown the presence of subtle radionuclide uptake predominating in the painful areas along the lower limb muscle fascias and in para-articular tissues in all tested patients.[17] This was not found in fibromyalgic controls.

Fatigue, sleep disturbances with unrereshing sleep, and sometimes headaches may be very disabling and often deeply impacts professional and personal life. A case-control study conducted by AFSSAPS pointed out chronic fatigue as more frequent and more pronounced in patients with than without MMF in deltoid muscle (http://afssaps.sante.fr/htm/10/myofasci/etude.pdf). In fact, a majority of patients fulfil international criteria of chronic fatigue syndrome.[18] Consequently, history of exposure to alum-containing vaccines should be checked carefully in patients with CFS, and muscle biopsy searching persistent MMF at site of injection should be considered when chronology is consistent, even many years after onset of symptoms.

CNS involvement is assessed by cognitive dysfunction. Patients complain of subjective memory impairment, difficulties in sustaining attention, and mood disturbancies. Although often disabling, cognitive dysfunction is often underestimated or remains undetected by routine examination. A comprehensive battery of neuropsychological tests in unselected MMF patients without MS showed alterations in all individuals, consistent with mild cognitive impairment (MCI) but including at least one test reaching the dementia threshold in 96%.[19] Compared to arthritis controls matched for pain severity and duration, depression and educational level, MMF patients displayed distinctive impairment of visual memory, working memory and dichotic listening, a pattern suggestive of cortico-subcortical organic damage involving fronto-parieto-thalamo-striatal areas, with deep white matter alterations.[19] Very similar cognitive alterations have been documented workers exposed to inhaled Al fumes or powder.[20–22] These alterations are also reminiscent of those described in HIV- or HCV-infected individuals.[19]

In addition to CFS, 15–20% of patients with MMF concurrently develop an autoimmune disease, the most frequent of which being multiple sclerosis (MS)-like demyelinating disorders [12–23, 23,24] Hashimoto's thyroiditis, and diffuse dysimmune neuromuscular diseases, such as dermatomyositis, necrotizing autoimmune myopathy, myasthenia gravis, and inclusion body myositis. Even in the absence of overt autoimmune disease, low titers of various autoantibodies, increased inflammatory biomarkers, and abnormal iron status are commonly detected.[4]

Taken individually, none of the clinical manifestations commonly associated with persistent MMF is specific of a given cause. Combination of chronic myalgias, fatigue, and cognitive dysfunction is consistent with CFS,[18] a poorly understood condition also known as myalgic encephalomyelitis,[25] which may be triggered by various infectious and non-infectious agents. We previously noted the closely similar structure of symptoms in individuals with MMF and with the so-called Gulf war syndrome[4] which is increasingly recognized as linked to multiple vaccinations,[26,27] with special emphasis put on anthrax vaccine, an alum-adjuvanted vaccine administered in 6 shots, that was recently shown to also induce MMF.[13] On these grounds, we proposed to consider MMF-associated symptoms as an adjuvant-induced syndrome.[28] Therefore, we fully support the term ASIA (autoimmune/inflammatory syndrome induced by adjuvants) coined by Pr Shoenfeld to designate these symptoms, regardless of the nature of the involved immunologic adjuvant (alum, silicone gel, viral components, etc).[5]

Handling and transport of poorly soluble nanomaterials by phagocytes : a possible clue for understanding MMF and ASIA

Go to:

For decades, aluminium oxyhydroxide, is the most commonly used adjuvant in human and veterinary vaccines. The mechanism by which it stimulates the immune response remains incompletely understood. [29]

Imbalance between the huge number of alum-vaccine receivers and the small number of biopsy-proven MMF cases strongly suggest that individual susceptibility factors play a crucial role in intolerance to alum. In rats, the genetic background strongly influences the size of lesions induced by i.m. injection of alum.[6] Adverse response to alum injection may also depend on susceptibility genes, such as HLA-DRB1*01, that may favour the development of autoimmune diseases.[30] Thus, aluminium likely represents one environmental factor able to trigger adverse effects in individuals with as yet largely unknown susceptibility genes. In keeping with this view, several closely related conditions have been shown to be associated with Al overload, including MMF,[14] idiopathic CFS,[31] and MS.[32] Moreover, strong suspicion of a possible link between Gulf war syndrome and alum administration has been experimentally supported.[33] Quite logically, questions are currently burgeoning about the exact safety level of aluminium adjuvants.[34]

However, if biopersistence of the adjuvant in the body is a priori undesirable, the exact significance of MMF remains uncertain since a conceptual link is still a missing between the observed persistence of particle-loaded MPs at site of previous immunization and the systemic, especially neurologic, clinical manifestations. Alum is potentially highly neurotoxic,[33] but it is used at concentrations viewed as an acceptable compromise between adjuvanticity and toxicity by industry and regulatory agencies. In fact, the potential toxicity of alum will be influenced by whether the bioactive nanomaterial remains localized at injection points or rather scatters and accumulates in distant organs and tissues. Characterization of the fate of i.m. injected particles is therefore crucial for understanding pathophysiology of MMF and related disorders.

A reference study based on isotopic ^{26}Al showed poor ^{26}Al clearance in the urine after i.m. injection of isotopic alum to rabbits (6% at d28 endpoint), and detected ^{26}Al, in an unknown form, in lymph nodes, spleen, liver, and brain.[35] However, as for other slowly biodegradable nanomaterials, the biodistribution of alum particles following injection into muscle is currently unknown.

Aluminium oxyhydroxide is composed of micron/submicron-sized aggregates of nano-sized (ca 13 nm) particles and these aggregates were initially believed to remain extracellular until their complete solubilisation in interstitial fluids.[35] We now know that quite the reverse is the case and that APCs avidly take up alum particles,[36] and, in so-doing, become long-lived cells,[37] and impede alum solubilization.[2] Inflammatory monocytes (MOs) are attracted into muscle by danger signals, becoming macrophages and MO-derived dendritic cells (DCs), before migrating to the draining lymph nodes (DLNs).[38] Since one function of migratory DCs is to transfer antigenic material to a large network of distant resident APCs, we examined if fluorescent nanomaterials injected into muscle could translocate to distant organs as part of a general mechanism linked to phagocytosis.

Preliminary results have substantiated this view.[39,40] We observed that fluorescent surrogates of alum particles injected into mouse muscle were rapidly taken up by macrophages to form a MMF-like granuloma. An important proportion of particles escaped the injected muscle, mainly within immune cells, gaining access to the regional lymph nodes. Then particle-loaded cells exited the lymphatic system to reach the blood stream (presumably through the thoracic duct, a terminal lymphatic vessel plugged to the subclavian vein), allowing them to gain access to distant organs such as spleen, liver and, eventually, the brain. Using lymph node ablation and genetically manipulated animals, we documented that systemic biodistribution of particles injected into muscle necessitates early cell loading in muscle or lymph nodes, and crucially depend on the presence of attracting signals for monocytes (namely the MCP-1/CCL2 chemokine) in tissues. Thus, immune cells loaded with alum-like particles circulate after the i.m. injection and can reach distant tissues such as brain, especially if they produce attracting signals for inflammatory cells or exhibit weak blood brain barrier (BBB).[39,40] This may also apply to other poorly degradable nanomaterials such as silicone, another compound suspected to cause ASIA.[5] Of course, lot remains to be done to determine if, in what conditions, and to what extent alum and other mineral particles gaining access to the brain by a Trojan horse mechanism, as HIV and HCV particles do, can cause significant inflammatory and neurotoxic damage.

In conclusion, MMF revealed an almost complete lack of knowledge on the fate, systemic diffusion, and long-term safety of alum particles. On the grounds of our clinical and experimental data, we believe that increased attention should be paid to possible long-term neurologic effects of continuously escalating doses of alum-containing vaccines administered to the general population. Special emphasis should be put on individuals with immature/altered BBB or inflammatory states.

The common immunogenic etiology of chronic fatigue syndrome: from infections to vaccines via adjuvants to the ASIA syndrome.

Rosenblum H[1], Shoenfeld Y, Amital H.

Author information

Abstract

Chronic fatigue syndrome (CFS) is characterized by unexplained fatigue that lasts for at least 6 months with a constellation of other symptoms. Most cases start suddenly, and are usually accompanied by a flu-like illness. It is a symptom-based diagnosis of exclusion, the pathogenesis of which is unknown. Studies have examined and hypothesized about the possible biomedical and epidemiologic characteristics of the disease, including genetic predisposition, infections, endocrine abnormalities, and immune dysfunction and psychological and psychosocial factors. Recently, the AISA (autoimmune/inflammatory syndrome induced by adjuvants) syndrome was recognized, indicating the possible contribution of adjuvants and vaccines to the development of autoimmunity.

Macrophagic myofaciitis a vaccine (alum) autoimmune-related disease.

Israeli E[1], Agmon-Levin N, Blank M, Shoenfeld Y.

Author information

Abstract

Macrophagic myofasciitis (MMF) is an immune-mediated condition first reported in 1998. MMF is characterized by post-vaccination systemic manifestations as well as local-stereotyped and immunologically active lesion in the site of inoculation (deltoid muscle). MMF systemic symptoms included myalgias, arthralgias, marked asthenia, muscle weakness, chronic fatigue, and fever. Recently, studies demonstrated that the local lesion is due to persistence for years at site of injection of an aluminum (Al(OH)3) adjuvant commonly used in human vaccines. Time elapsed from last immunization with an Al(OH)3-containing vaccine to muscle biopsy range from 3 months to 8 years; in rare cases, MMF may be diagnosed even 10 years post-vaccination. The discrepancy between the wide applications of aluminum hydroxide-containing vaccines and the very limited number of MMF cases reported may be resolved by observations suggesting that aluminum-containing vaccinations may trigger MMF in genetically susceptible subjects carrying the HLA-DRB1*01. Thus, MMF may be defined as an emerging novel condition that may be triggered by exposure to alum-containing vaccines, in patients with a specific genetic background, and this temporal association may be exhibited from a few months up to 10 years.

ASIA OR SHOENFELD'S SYNDROME: HIGHLIGHTING DIFFERENT PERSPECTIVES FOR DIFFUSE CHRONIC PAIN

Jozélio Freire Carvalho*, Solange Murta Barros**, Jaime C. Branco***, João Eurico Fonseca****

Is the Gulf War Syndrome (GWS) and the silicone related scleroderma –like syndrome spectres of the same disease? What do they have in common with a rare aluminium induced myopathic syndrome described for the first time in France in 1998? The logic answer was suggested by an elegant integration of the existing evidence into the autoimmune/inflammatory syndrome induced by adjuvants (ASIA) proposed recently by Shoenfeld in a paper published in *Journal of Autoimmunity*[1]. A mosaic of environmental factors can be classified as adjuvants. In fact, we know for decades a variety of compounds that are able to induce autoimmunity in animal models and used in clinical practice to increase the immunogenicity of vaccines, but also known to be able, in genetic susceptible individuals, to induce autoimmune diseases[2,3]. In this vast group of substances bacterial antigens, hormones, aluminium, silicone and several other molecules have been included[4].

The GWS was described in veterans that were suffering from atypical rheumatic symptoms, such as arthralgia, myalgia, lymphadenopaty, chronic fatigue syndrome, malar rash and autoimmune thyroiditis[5].

A cohort study performed 10 years ago compared the titter of anti squalene antibodies of 144 Golf War immunized veterans or medical employees, 48 blood donors, 40 systemic lupus erythematosus patients, 34 silicone breast implant recipients and 30 chronic fatigue syndrome patients. The majority (95%) of overtly ill deployed GWS patients had antibodies to squalene. All (100%) GWS patients immunized for service in Desert Shield/ /Desert Storm who were not in the fighting front had antibodies to squalen. In contrast, none (0%) of the veterans that were in the fighting zone and were not showing signs and symptoms of GWS have antibodies to squalen. Neither patients with idiopathic autoimmune disease nor healthy controls had detectable serum antibodies to squalene. The majority of symptomatic GWS patients had serum antibodies to squalene[6]. The authors proposed that GWS was not a result of the exposition to weapons but rather induced by the intense vaccination program that they were submitted to. It is ironic that more solders were ill due to an oil adjuvant injected in their organisms than fighting against the hostile environment and the armed enemies.

Silicon was considered an inert material and thus unable to induce immune reactions. Recent metanalysis have supported this view, as the risk of silicon exposed individuals for developing a diffuse connective tissue disease is only 0.8%, not significantly higher than the risk of the general population. However, that is not the case for more unspecific symptoms such as arthralgia and myalgia and even some diffuse neurologic manifestations that appear to be more common in individuals exposed to silicon implants[7]. The possible association between chronic fatigue syndrome, fibromyalgia, and previous silicone mammoplasty was proposed almost two decades ago[8].

The post vaccination muscle disease described by Gehardi *et al.* in 1987 is of particular interest as it is based in well defined histologic features[9]. It is a miofasceitis that has the presence of macrophages with aluminum inclusions, which occurs associated with vaccination. Clinically the disease is expressed by systemic symptoms such as fatigue, myalgia, arthalgia, fever and, in some cases, by a demyelinating condition similar to Guillain-Barré, with electromyographic changes. Elevated acute

Table I. Criteria suggested by Shoenfeld for ASIA diagnosis

Major Criteria

- Exposure to an external stimuli (infection, vaccine, silicone, adjuvant) prior to clinical manifestations
- The appearance of 'typical' clinical manifestations:
  - Myalgia, myositis or muscle weakness
  - Arthralgia and/or arthritis
  - Chronic fatigue, un-refreshing sleep or sleep disturbances
  - Neurological manifestations (especially associated with demyelination)
  - Cognitive impairment, memory loss
  - Pyrexia, dry mouth
- Removal of inciting agent induces improvement
- Typical biopsy of involved organs

Minor Criteria

- The appearance of autoantibodies or antibodies directed at the suspected adjuvant
- Other clinical manifestations (i.e. irritable bowel syndrome)
- Specific HLA (i.e. HLA DRB1, HLA DQB1)
- Evolvement of an autoimmune disease

For ASIA's diagnosis: at least 2 major criteria or 2 minor and 1 major.

phase proteins and creatine quinase also occur. The same group determined that the disease occurs only in HLA DRB1*01 positive individuals[9]. On top of that, it was shown that aluminum can persist in the local of injection, up to 10 years after vaccine administration, which can explain the persistence of this condition in some individuals[10].

These conditions and other observations, regarding for instance de H1N1 vaccination, have motivated the definition of the ASIA syndrome, with the criteria proposed by Shoenfeld listed in Table I[1]. These criteria, if properly validated, are of great clinical relevance, as they raise a major clinical doubt on the classification of some patients with chronic pain syndromes, as chronic fatigue syndrome, or even fibromyalgia. In fact, if we compare the cardinal symptoms of the Shoenfeld's ASIA syndrome with the typical clinical manifestations of patients with diffuse chronic pain we came quickly to the conclusion that reviewing the recent exposition to adjuvants and other potential exogenous stimulus seems to be a wise attitude. This is also in line with the characteristic symptoms of fibromyalgia and chronic fatigue syndrome that frequently occur in patients with well-defined Lyme disease, even after adequate treatment. Lyme disease is caused by an infection due to *Borrelia burgdorferi* spirochete and most of the clinical symptoms are in fact a consequence of an immune response to this infectious agent. Although a biological relationship between Lyme disease and diffuse pain syndromes has not been established, in fact this can be encompassed by the ASIA syndrome[11]. In addition, recent studies have detected the presence of retroviral sequences like xenotropic murine leukemia virus-related virus (XMRV) and polytropic murine leukemia virus related--virus (PMLV) in chronic fatigue syndrome patients, expanding, in fact, the need for thinking on alternative diagnosis in patients classified into these conditions[12]. Consequently, countries such as Australia, Canada, New Zealand and the UK elaborated restrictive guidelines for "blood donors with a history of current diagnosis of CFS". If upcoming research will confirm these observations and validate the ASIA/Shoenfeld criteria, a major paradigm shift will have to occur in the way rheumatologists perceive some cases of diffuse chronic pain. Interestingly, in this issue of Acta Reumatologica Portuguesa 2 case reports related to the ASIA/Shoenfeld are reported[13,14].

Chronic fatigue syndrome in patients with macrophagic myofasciitis

Macrophagic myofasciitis (MMF), a condition first reported in France in 1998, is defined by the presence of a stereotyped and immunologically active lesion at deltoid muscle biopsy (1,2). It was recently demonstrated that this lesion is an indicator of long-term persistence of the immunologic adjuvant aluminum hydroxide within the cytoplasm of macrophages at the site of previous intramuscular (IM) injection (2). MMF is typically detected in patients with diffuse arthromyalgias that have appeared subsequent to aluminum hydroxide administration in the absence of a clearly defined anatomic substratum (2). Patients also report unexplained chronic fatigue (1). These manifestations are reminiscent of the so-called chronic fatigue syndrome (CFS), a poorly understood condition manifesting as disabling fatigue, musculoskeletal pain, sleep disturbance, impaired concentration, and headaches (3). The present study was conducted to determine the proportion of MMF patients fulfilling international criteria for CFS.

Thirty unselected consecutive patients with biopsy-proven MMF identified in Créteil and Bordeaux were retrospectively included, regardless of symptoms that led to indication of muscle biopsy. As previously described (2), MMF was assessed by 1) well-circumscribed sheets of densely-packed, large, nonepithelioid macrophages with a finely granular, periodic acid–Schiff–positive content, in the connective structures of deltoid muscle; 2) lymphocytic infiltrates intermingled with macrophages and forming microvascular cuffs; and 3) absence of significant muscle fiber injury (see Figure 1). In each patient, we determined, through both chart review and either direct patient questioning or telephone interview, 1) the presence of chronic fatigue of >6 months' duration, 2) the alleged severity of fatigue, and 3) the presence of CFS according to Centers for Disease Control and Prevention (CDC) criteria (1994) (4) or Oxford criteria (1991) (5). In addition, in 20 patients, we retrospectively evaluated history of immunization as well as prevalence of fever and neurologic features suggestive of central nervous system demyelinating disease; laboratory findings, including erythrocyte sedimentation rate, creatine kinase levels, and ^{67}Ga scintigraphy; and responsiveness to steroids.

The male:female ratio was 1:2. The mean age of patients was 52 years (range 12–78 years). Chronic fatigue was found in 28 of 30 patients (93%) and was considered disabling in 26 of 30 patients (87%). Sixteen patients (53%) fulfilled CFS criteria from either the CDC (14 of 30 patients, 47%) or Oxford (12 of 30 patients, 40%), 11 of 30 patients (37%) fulfilled both CDC and Oxford criteria. Other symptoms, laboratory findings, and steroid responsiveness are detailed in Table 1. ^{67}Ga scintigraphy was performed in 5 patients and showed increased levels of ^{67}Ga uptake in muscle and paraarticular areas, mainly in lower limbs. A history of vaccination was available for 19 of 20 patients. All 19 patients had received IM administration of aluminum-containing vaccine prior to the onset of CFS symptoms, and the delay from the last vaccination to the first manifestations ranged from 1 month to 72 months (median 12 months).

We have previously determined that myalgias are a major symptom in patients with MMF. The prevalence of myalgias was much higher in such patients than in other patients who had undergone deltoid muscle biopsies at the same time in the same centers (85% versus 45%; $P < 0.0001$ by Fisher's exact test) (2). We show now that chronic disabling fatigue is a symptom as frequent as diffuse myalgias in patients with MMF (87%), a finding also noted in the French Institut de Veille Sanitaire exploratory investigation report (6). More than half of the patients also reported other manifestations of CFS. Therefore, MMF should be alternatively considered as a cause of CFS or as an additional exclusion criterion, along with rheumatoid arthritis, lupus, and other diseases, for the diagnosis of idiopathic CFS (4). Consequently, we suggest that patients with CFS should be carefully checked for a history of IM administration of aluminum hydroxide, and, if there is consistent chronology, a muscle biopsy to search for MMF at the site of injection should be considered, even many years after onset of symptoms.

Pathophysiology of CFS is still fiercely debated by psychologists, neuroendocrinologists, and immunologists. Chronic immune stimulation that fails to switch off has been previously reported as a possible cause of CFS (7–9), and such a situation may very well result from persistence of the immunologic adjuvant aluminum hydroxide within antigen-presenting cells (2,10). Therefore, MMF may well represent a paradigm for CFS of immunologic origin. We believe that clarification of MMF pathophysiology would significantly contribute to the understanding of the whole spectrum of chronic fatigue and its syndromes.

CASE REPORT

Identical Twins With Macrophagic Myofasciitis: Genetic Susceptibility and Triggering by Aluminic Vaccine Adjuvants?

S. GUIS,[1] J. P. MATTEI,[1] F. NICOLI,[2] J. F. PELLISSIER,[3] G. KAPLANSKI,[1] D. FIGARELLA-BRANGER,[3] G. C. MANEZ,[1] G. M. ANTIPOFF,[1] AND J. ROUDIER[4]

Introduction

Macrophagic myofasciitis (MMF) is an inflammatory myopathy, recently described (1,2). Clinical symptoms include myalgias, arthralgias, muscle weakness, asthenia, and fever. Diagnosis is based on deltoid muscle biopsy that usually shows specific histologic abnormalities including infiltration of connective tissue structures by densely packed large and grossly rounded CD68+ histiocytes. These cells are characterized by central, round, and often nucleolated nuclei, and clear, slightly basophilic cytoplasms with fine PAS-positive granules (1). Aluminic vaccine adjuvants (3) as well as *Tropheryma whippelii* infection (4,5) have been recently suggested as possible etiopathogenic agents of MMF. We report 2 cases of MMF observed after hepatitis B vaccination in twin sisters. This observation illustrates the importance of the genetic background in MMF, and its possible triggering by aluminic vaccines.

Case report

Two 64-year-old identical twin sisters were referred to our department for possible rheumatoid arthritis. They had no family history of inflammatory disease. The first sister's medical history was unremarkable until December 1993, 6 months after she received a third and final injection of hepatitis B vaccine (Engerix B vaccination, containing aluminic hydroxide, vaccination in April, May, and July, 1993) in the left deltoid. At this time, she began complaining of arthritis. On physical examination, arthritis involving both wrists and the proximal and distal interphalangeal joints of the hands and feet were noted. Arthritis was associated with myalgias and upper limb muscle weakness. She complained of dry eyes and mouth and of oral aphthae. Treatment with oral prednisone (5 mg/day) and methotrexate (20 mg weekly) proved ineffective. Neurologic examination revealed distal paresthesias and cramps affecting the 4 limbs, slight weakness of hand muscles, no pyramidal syndrome, and partial visual acuity loss. Sicca syndrome was confirmed by Schirmer's test. Salivary gland biopsy showed Chisholm 3 grade, consistent with the diagnosis of Gougerot-Sjögren's syndrome. Erythrocyte sedimentation rate (ESR) was 20 mm/hour, C-reactive protein was 30 mg/l. Serum creatine kinase and cerebrospinal fluid were normal. Antinuclear antibodies (ANA) were weakly positive (200 UI/ml) with spotted pattern. Anti-DNA, anti-SSA, anti-SSB, rheumatoid factor, and anticardiolipin antibodies were not detected. Serologic tests for hepatitis A, B, C, and parvovirus B 19 were negative. The patient typed as HLA–A01, A02, B13, B35, DRB1*01, DRB1*07. Electromyography showed a slight myogenic aspect. Radiographs of the hands, shoulders, wrists, ankles, and feet were normal. Technetium bone scan showed symmetric increased uptake of the main joints. Upper right limb muscle magnetic resonance imaging (MRI) showed general muscle atrophy. The morphology and chronology of the visual-, auditory-, motor-, and somaesthesic-evoked responses were normal, and cerebral MRI was normal. Esophago-gastro-duodenoscopy was normal with no evidence of PAS+ cells on duodenal biopsies, the culture for *Tropheryma whippelii* in duodenal biopsies was negative. Diagnosis of MMF was obtained by histologic examination of biopsy sample of the left deltoid muscle, which showed stereotypical epi-, peri- and endomysial infiltrates of densely packed CD68+ macrophages twice associated T and B cells (Figure 1). Electron microscopic examination was not performed on this biopsy.

The twin sister had a similar clinical presentation with bilateral arthritis of wrists, shoulders, temporomandibular joints, hands, and ankles. She received prednisone (15

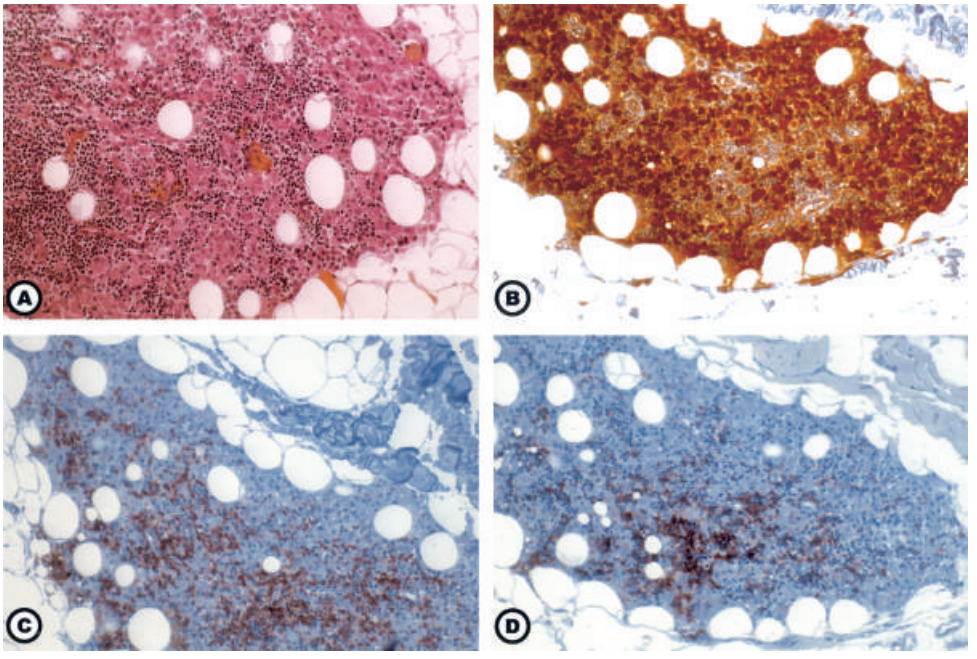

Figure 1. Deltoid muscle biopsy (light microscopy, serial sections, original magnification × 125) demonstrating macrophagic myofasciitis in patient 1. **A,** inflammatory infiltrates of adipose tissue of fascia (fasciitis) by macrophages notably large in size and lymphocytes (Hematoxylin and eosin stained). **B,** immunoreactivity of CD68+ showing large predominance of macrophages. **C,** immunoreactivity of CD3+ mononucleated cells corresponding to T cells. **D,** immunoreactivity of DBB42 antibody showing B cells.

mg/day), hydroxychloroquine (400 mg/day), and methotrexate (20 mg/week). Her medical history was unremarkable except for mild asthma and high blood pressure. On admission, she reported peripheral arthritis with myalgias. Neurologic examination showed distal paresthesias and cramps of the 4 limbs, severe weakness of the hand muscles, hyperreflexia of the right upper limb, right Hoffmann's sign, and normal plantar reflexes urgency of micturition. The symptoms had started 7 months after intramuscular hepatitis B vaccination in the left deltoid (Engerix B containing aluminic hydroxide, vaccination in December 1995, February, and July 1997). ESR was 30 mm at one hour. Serum creatine kinase was normal. ANA, anti-DNA, anti-SSA, anti-SSB, rheumatoid factor, and anticardiolipin antibodies were negative. Serologic tests for hepatitis A, C and parvovirus B 19 were negative. Hepatitis B serology confirmed the vaccination status, specifically the absence of hepatitis B surface, anti-hepatitis B core and anti-hepatitis B e antigens, and the presence of anti-hepatitis B surface antibodies. The patient typed as HLA–A01, A02, B13, B35, DRB1*01, DRB1*07. Schirmer's test was positive. Electromyography showed myogenic aspect. Radiographs of the hands, shoulders, wrists, ankles, and feet were normal. MRI of the superior right limb muscles showed a diffuse muscle atrophy. Evoked potentials and brain MRI were normal. Esophago-gastro-duodenoscopy was normal and cultures for *Tropheryma whippelii* in duodenal biopsies were negative. Once again, muscle biopsy of the left deltoid muscle confirmed the diagnosis of MMF.

Discussion

We report cases of MMF affecting twin sisters, which occurred 6–7 months after hepatitis B vaccination. In both cases, clinical symptoms were remarkable because of the importance of arthritis associated with muscle involvement. Laboratory tests showed slight inflammation, and normal muscle enzyme levels. Remarkably, although both twin sisters had had complete hepatitis B vaccination, only the second had developed antibodies to the hepatitis B surface antigen. Indeed, the HLA–DRB1*07 allele, which both twins expressed, is associated with poor humoral responses to hepatitis B vaccination (6). Thus, antibody responses to hepatitis B surface antigen may not be crucial to the development of MMF.

Conversely, the role of vaccines containing aluminum hydroxide in the pathogenesis of MMF has been recently suggested (3). Despite the fact that histologic abnormalities are present only at the site of vaccination, systemic symptoms are generally observed. However, there is a discrepancy between the wide usage of aluminum hydroxide-containing vaccines (especially anti hepatitis B vaccines) and the very limited number of MMF cases reported so far. We did not perform electron microscopy on muscle biopsies to check for aluminium inclusions in macrophages. This report suggests that additional factors, perhaps genetic, may influence the occurrence of MMF. Aluminum hydroxyde may trigger unusual muscle inflammatory infiltrates in patients with increased susceptibility to inflammatory disease or decrease macrophages' capacity for aluminum hydroxyde digestion. The nature of the predis-

posing genetic factor is unknown. HLA–DRB1*01, which was found in both sisters (identical twins) could be a potential candidate. Thus, our observation suggests that aluminic vaccinations may trigger MMF on the HLA–DRB1*01 genetic background.

Aluminum phagocytosis in quadriceps muscle following vaccination in children: relationship to macrophagic myofasciitis.

Lacson AG[1], D'Cruz CA, Gilbert-Barness E, Sharer L, Jacinto S, Cuenca R.

Author information

Abstract

Macrophagic myofasciitis (MMF) is a rare, seemingly emerging entity among adult patients in France. We encountered two children with the first two cases of MMF in North America. A 5-year-old male with chronic intestinal pseudo-obstruction required nighttime parenteral nutrition. Abnormal pupillary reflexes and urinary retention suggested a diffuse dysautonomia, which prompted a neurological diagnostic work-up. A 3-year-old child had developmental delay and hypotonia. Both children received age-appropriate immunizations. Quadriceps muscle biopsy from each child showed the typical patchy, cohesive centripetal infiltration of alpha-1-antitrypsin+, alpha-1-antichymotrypsin+, CD68+, PAS+, CD1a-, S-100-, factor XIII- granular macrophages with adjacent myofiber atrophy, dilated blood vessels, and mild endomysial and perimysial fibrosis. No myonecrosis was observed and no discrete granulomas were seen. A single aluminum peak was demonstrated on energy dispersive X-ray microanalysis. The etiology of the clinical symptoms in these cases and in cases reported as MMF remains intriguing. Despite numerous stains to demonstrate organisms, most infectious causes leading to macrophage activation were ruled out. These cases are being reported to increase awareness of this condition and to encourage a systematic epidemiologic and clinicopathologic study in North America.

The development of rheumatoid arthritis after recombinant hepatitis B vaccination.

Pope JE[1], Stevens A, Howson W, Bell DA.

Author information

Abstract

OBJECTIVE: Hepatitis B vaccination has been associated with reactive arthritis and rarely rheumatoid arthritis (RA). We defined the clinical, serologic, and immunogenetic background of patients developing RA, soon after recombinant hepatitis B vaccination.

METHODS: The clinical, serologic, and HLA antigens of a cluster of firefighters who developed arthritis after prophylactic recombinant hepatitis B vaccination (5 subjects), as well as a second group of sporadic cases of arthritis (6 patients) after hepatitis B vaccination are described.

RESULTS: Ten of 11 patients fulfilled revised American College of Rheumatology criteria for RA. All cases had persistent arthritis for more than 6 months; at 48 months followup 2 cases no longer had inflammatory arthritis. Nine patients required disease modifying antirheumatic drugs. Five subjects were HLA-DR4 positive. HLA class II genes expressing the RA shared motif were identified in 9/11 patients genotyped for HLA-DRbeta1 and DQbeta1 alleles (0401, 0101, or 0404). All the firefighters shared the HLA-DRbeta1 allele 0301 and the DQbeta1 allele 0201, with which it is in linkage disequilibrium.

CONCLUSION: These polymorphic residues in the binding site of the MHC class II molecules of the affected patients appear capable of binding some peptide sequences of the recombinant vaccine peptides they received and may be responsible for hepatitis B vaccine triggering development of RA in these cases. Recombinant hepatitis B vaccine may trigger the development of RA in MHC class II genetically susceptible individuals.

Transverse myelitis and vaccines: a multi-analysis.

Agmon-Levin N[1], Kivity S, Szyper-Kravitz M, Shoenfeld Y.

Author information

Abstract

Transverse myelitis is a rare clinical syndrome in which an immune-mediated process causes neural injury to the spinal cord. The pathogenesis of transverse myelitis is mostly of an autoimmune nature, triggered by various environmental factors, including vaccination. Our aim here was to search for and analyze reported cases of transverse myelitis following vaccination. A systematic review of PubMed, EMBASE and DynaMed for all English-language journals published between 1970 and 2009 was preformed, utilizing the key words transverse myelitis, myelitis, vaccines, post-vaccination, vaccination and autoimmunity. We have disclosed 37 reported cases of transverse myelitis associated with different vaccines including those against hepatitis B virus, measles-mumps-rubella, diphtheria-tetanus-pertussis and others, given to infants, children and adults. In most of these reported cases the temporal association was between several days and 3 months, although a longer time frame of up to several years was also suggested. Although vaccines harbor a major contribution to public health in the modern era, in rare cases they may be associated with autoimmune phenomena such as transverse myelitis. The associations of different vaccines with a single autoimmune phenomenon allude to the idea that a common denominator of these vaccines, such as an adjuvant, might trigger this syndrome.

The spectrum of post-vaccination inflammatory CNS demyelinating syndromes.

Karussis D, Petrou P.

Abstract

A wide variety of inflammatory diseases temporally associated with the administration of various vaccines, has been reported in the literature. A PubMed search from 1979 to 2013 revealed seventy one (71) documented cases. The most commonly reported vaccinations that were associated with CNS demyelinating diseases included influenza (21 cases), human papilloma virus (HPV) (9 cases), hepatitis A or B (8 cases), rabies (5 cases), measles (5 cases), rubella (5 cases), yellow fever (3 cases), anthrax (2 cases),meningococcus (2 cases) and tetanus (2 cases). The vast majority of post-vaccination CNS demyelinating syndromes, are related to influenza vaccination and this could be attributed to the high percentage of the population that received the vaccine during the HI1N1 epidemia from 2009 to 2012. Usually the symptoms of the CNS demyelinating syndrome appear few days following the immunization (mean: 14.2 days) but there are cases where the clinical presentation was delayed (more than 3 weeks or even up to 5 months post-vaccination) (approximately a third of all the reported cases). In terms of the clinical presentation and the affected CNS areas, there is a great diversity among the reported cases of post-vaccination acute demyelinating syndromes. Optic neuritis was the prominent clinical presentation in 38 cases, multifocal disseminated demyelination in 30, myelitis in 24 and encephalitis in 17. Interestingly in a rather high proportion of the patients (and especially following influenza and human papiloma virus vaccination-HPV) the dominant localizations of demyelination were the optic nerves and the myelon, presenting as optic neuritis and myelitis (with or without additional manifestations of ADEM), reminiscent to neuromyelitic optica (or, more generally, the NMO-spectrum of diseases). Seven patients suffered an NMO-like disease following HPV and we had two similar cases in our Center. One patient with post-vaccination ADEM, subsequently developed NMO. Overall, the risk of a demyelinating CNS disease following vaccination, although non-negligible, is relatively low. The risk of onset or relapse of CNS demyelination following infections against which the vaccines are aimed to protect, is substantially higher and the benefits of vaccinations surpass the potential risks of CNS inflammation. This does not in any way exempt us from“learning” the lessons taught by the reported cases and searching new and safer ways to improve vaccination techniques and increase their safety profile.

Hepatitis B vaccine and the risk of CNS inflammatory demyelination in childhood.

Mikaeloff Y[1], Caridade G, Suissa S, Tardieu M.

Author information

Abstract

BACKGROUND: The risk of CNS inflammatory demyelination associated with hepatitis B (HB) vaccine is debated, with studies reporting conflicting findings.

METHODS: We conducted a population-based case-control study where the cases were children with a first episode of acute CNS inflammatory demyelination in France (1994-2003). Each case was matched on age, sex, and geographic location to up to 12 controls, randomly selected from the general population. Information on vaccinations was confirmed by a copy of the vaccination certificate. The odds ratios (ORs) of CNS inflammatory demyelination associated with HB vaccination were estimated using conditional logistic regression.

RESULTS: The rates of HB vaccination in the 3 years before the index date were 24.4% for the 349 cases and 27.3% for their 2,941 matched controls. HB vaccination within this period was not associated with an increase in the rate of CNS inflammatory demyelination (adjusted OR, 0.74; 0.54-1.02), neither >3 years nor as a function of the number of injections or brand type. When the analysis was restricted to subjects compliant with vaccination, HB vaccine exposure >3 years before index date was associated with an increased trend (1.50; 0.93-2.43), essentially from the Engerix B vaccine (1.74; 1.03-2.95). The OR was particularly elevated for this brand in patients with confirmed multiple sclerosis (2.77; 1.23-6.24).

CONCLUSIONS: Hepatitis B vaccination does not generally increase the risk of CNS inflammatory demyelination in childhood. However, the Engerix B vaccine appears to increase this risk, particularly for confirmed multiple sclerosis, in the longer term. Our results require confirmation in future studies.

Evolution of multiple sclerosis in France since the beginning of hepatitis B vaccination.

Le Houézec D[1].

Author information

Abstract

Since the implementation of the mass vaccination campaign against hepatitis B in France, the appearance of multiple sclerosis, sometimes occurring in the aftermath of vaccinations, led to the publication of epidemiological international studies. This was also justified by the sharp increase in the annual incidence of multiple sclerosis reported to the French health insurance in the mid-1990s. Almost 20 years later, a retrospective reflection can be sketched from these official data and also from the national pharmacovigilance agency. Statistical data from these latter sources seem to show a significant correlation between the number of hepatitis B vaccinations performed and the declaration to the pharmacovigilance of multiple sclerosis occurring between 1 and 2 years later. The application of the Hill's criteria to these data indicates that the correlation between hepatitis B vaccine and multiple sclerosis may be causal.

Measles-mumps-rubella-varicella combination vaccine and the risk of febrile seizures.

Klein NP[1], Fireman B, Yih WK, Lewis E, Kulldorff M, Ray P, Baxter R, Hambidge S, Nordin J, Naleway A, Belongia EA, Lieu T, Baggs J, Weintraub E; Vaccine Safety Datalink.

Author information

Abstract

OBJECTIVE: In February 2008, we alerted the Advisory Committee on Immunization Practices to preliminary evidence of a twofold increased risk of febrile seizures after the combination measles-mumps-rubella-varicella (MMRV) vaccine when compared with separate measles-mumps-rubella (MMR) and varicella vaccines. Now with data on twice as many vaccine recipients, our goal was to reexamine seizure risk after MMRV vaccine.

METHODS: Using 2000-2008 Vaccine Safety Datalink data, we assessed seizures and fever visits among children aged 12 to 23 months after MMRV and separate MMR + varicella vaccines. We compared seizure risk after MMRV vaccine to that after MMR + varicella vaccines by using Poisson regression as well as with supplementary regressions that incorporated chart-review results and self-controlled analyses.

RESULTS: MMRV vaccine recipients (83,107) were compared with recipients of MMR + varicella vaccines (376,354). Seizure and fever significantly clustered 7 to 10 days after vaccination with all measles-containing vaccines but not after varicella vaccination alone. Seizure risk during days 7 to 10 was higher after MMRV than after MMR + varicella vaccination (relative risk: 1.98 [95% confidence interval: 1.43-2.73]). Supplementary analyses yielded similar results. The excess risk for febrile seizures 7 to 10 days after MMRV compared with separate MMR + varicella vaccination was 4.3 per 10,000 doses (95% confidence interval: 2.6-5.6).

CONCLUSIONS: Among 12- to 23-month-olds who received their first dose of measles-containing vaccine, fever and seizure were elevated 7 to 10 days after vaccination. Vaccination with MMRV results in 1 additional febrile seizure for every 2300 doses given instead of separate MMR + varicella vaccines. Providers who recommend MMRV should communicate to parents that it increases the risk of fever and seizure over that already associated with measles-containing vaccines.

Human papilloma virus vaccine and primary ovarian failure: another facet of the autoimmune/inflammatory syndrome induced by adjuvants.

Colafrancesco S[1], Perricone C, Tomljenovic L, Shoenfeld Y.

Author information

Abstract

PROBLEM: Post-vaccination autoimmune phenomena are a major facet of the autoimmune/inflammatory syndrome induced by adjuvants (ASIA) and different vaccines, including HPV, have been identified as possible causes.

METHOD OF STUDY: The medical history of three young women who presented with secondary amenorrhea following HPV vaccination was collected. Data regarding type of vaccine, number of vaccination, personal, clinical and serological features, as well as response to treatments were analyzed.

RESULTS: All three patients developed secondary amenorrhea following HPV vaccinations, which did not resolve upon treatment with hormone replacement therapies. In all three cases sexual development was normal and genetic screen revealed no pertinent abnormalities (i.e., Turner's syndrome, Fragile X test were all negative). Serological evaluations showed low levels of estradiol and increased FSH and LH and in two cases, specific auto-antibodies were detected (antiovarian and anti thyroid), suggesting that the HPV vaccine triggered an autoimmune response. Pelvic ultrasound did not reveal any abnormalities in any of the three cases. All three patients experienced a range of common non-specific post-vaccine symptoms including nausea, headache, sleep disturbances, arthralgia and a range of cognitive and psychiatric disturbances. According to these clinical features, a diagnosis of primary ovarian failure (POF) was determined which also fulfilled the required criteria for the ASIA syndrome.

CONCLUSION: We documented here the evidence of the potential of the HPV vaccine to trigger a life-disabling autoimmune condition. The increasing number of similar reports of post HPV vaccine-linked autoimmunity and the uncertainty of long-term clinical benefits of HPV vaccination are a matter of public health that warrants further rigorous inquiry.

A lowered probability of pregnancy in females in the USA aged 25-29 who received a human papillomavirus vaccine injection.

DeLong G[1].

Author information

Abstract

Birth rates in the United States have recently fallen. Birth rates per 1000 females aged 25-29 fell from 118 in 2007 to 105 in 2015. One factor may involve the vaccination against the human papillomavirus (HPV). Shortly after the vaccine was licensed, several reports of recipients experiencing primary ovarian failure emerged. This study analyzed information gathered in National Health and Nutrition Examination Survey, which represented 8 million 25-to-29-year-old women residing in the United States between 2007 and 2014. Approximately 60% of women who did not receive the HPV vaccine had been pregnant at least once, whereas only 35% of women who were exposed to the vaccine had conceived. For married women, 75% who did not receive the shot were found to conceive, while only 50% who received the vaccine had ever been pregnant. Using logistic regression to analyze the data, the probability of having been pregnant was estimated for females who received an HPV vaccine compared with females who did not receive the shot. Results suggest that females who received the HPV shot were less likely to have ever been pregnant than women in the same age group who did not receive the shot. If 100% of females in this study had received the HPV vaccine, data suggest the number of women having ever conceived would have fallen by 2 million. Further study into the influence of HPV vaccine on fertility is thus warranted.

Association of spontaneous abortion with receipt of inactivated influenza vaccine containing H1N1pdm09 in 2010-11 and 2011-12.

Donahue JG[1], Kieke BA[2], King JP[3], DeStefano F[4], Mascola MA[5], Irving SA[6], Cheetham TC[7], Glanz JM[8], Jackson LA[9], Klein NP[10], Naleway AL[11], Weintraub E[12], Belongia EA[13].

Author information

Abstract

INTRODUCTION: Inactivated influenza vaccine is recommended in any stage of pregnancy, but evidence of safety in early pregnancy is limited, including for vaccines containing A/H1N1pdm2009 (pH1N1) antigen. We sought to determine if receipt of vaccine containing pH1N1 was associated with spontaneous abortion (SAB).

METHODS: We conducted a case-control study over two influenza seasons (2010-11, 2011-12) in the Vaccine Safety Datalink. Cases had SAB and controls had live births or stillbirths and were matched on site, date of last menstrual period, and age. Of 919 potential cases identified using diagnosis codes, 485 were eligible and confirmed by medical record review. Exposure was defined as vaccination with inactivated influenza vaccine before the SAB date; the primary exposure window was the 1-28days before the SAB.

RESULTS: The overall adjusted odds ratio (aOR) was 2.0 (95% CI, 1.1-3.6) for vaccine receipt in the 28-day exposure window; there was no association in other exposure windows. In season-specific analyses, the aOR in the 1-28days was 3.7 (95% CI 1.4-9.4) in 2010-11 and 1.4 (95% CI 0.6-3.3) in 2011-12. The association was modified by influenza vaccination in the prior season (post hoc analysis). Among women who received pH1N1-containing vaccine in the previous influenza season, the aOR in the 1-28days was 7.7 (95% CI 2.2-27.3); the aOR was 1.3 (95% CI 0.7-2.7) among women not vaccinated in the previous season. This effect modification was observed in each season.

CONCLUSION: SAB was associated with influenza vaccination in the preceding 28days. The association was significant only among women vaccinated in the previous influenza season with pH1N1-containing vaccine. This study does not and cannot establish a causal relationship between repeated influenza vaccination and SAB, but further research is warranted.

Abstract

Background—Although vaccinia immunization is highly effective in preventing smallpox, post-vaccination reactions are common. Identifying genetic factors associated with AEs might allow screening before vaccinia administration and provide a rational basis for the development of improved vaccine candidates.

Methods—Two independent clinical trials in healthy, vaccinia-naïve adult volunteers were conducted with the Aventis Pasteur smallpox vaccine (APSV). Volunteers were assessed repeatedly for local and systemic AEs to vaccine and were genotyped using the same panel of 1442 single-nucleotide polymorphisms (SNPs).

CONFLICT OF INTEREST STATEMENT:
Financial Disclosures: Dr. Crowe reported being the recipient of research funding from Sanofi-Aventis, Vaxgen, and a joint STTR award with Mapp Pharmaceuticals. He has consulted for MedImmune, Vaxin, Evogenix, Symphogen, and Syngenta. Dr. Edwards reported being the recipient of research funding from Sanofi-Aventis, MedImmune, Vaxgen, Merck, and Wyeth. She has consulted for MedImmune and Wyeth. No other authors reported disclosures.
Role of the Sponsor: The funding organizations played no role in design and conduct of the study; collection, management, analysis, and interpretation of the data; or in the preparation, review, or approval of the manuscript.

Results—In the first study, thirty-six SNPs in 26 genes were associated with systemic AEs (p-value ≤ 0.05). In the second study, only those SNPs associated with AEs in the first sample were tested. In the final analysis, three SNPs were associated consistently with AEs in both studies. A nonsynonymous SNP in methylenetetrahydrofolate reductase (*MTHFR*) was associated with AE risk in both trials (odds ratio [OR]; 95% confidence interval [CI]); p-value [p]): (OR=2.3; CI=1.1–5.2; p=0.04) and (OR=4.1; CI=1.4–11.4; p<0.01). Two SNPs in the interferon regulatory factor 1 (*IRF1*) gene were associated with AE risk in both sample sets: (OR=3.2; CI=1.1–9.8; p=0.03) and (OR=3.0; CI=1.1–8.3; p=0.03).

Conclusions—Genetic polymorphisms in an enzyme previously associated with adverse reactions to a variety of pharmacologic agents (*MTHFR*) and an immunological transcription factor (*IRF1*) were associated with AEs after smallpox vaccination in two independent study samples. These findings highlight common genetic variants with promising clinical significance that merit further investigation.

adverse events; vaccination; smallpox; genetics; epidemiology

INTRODUCTION

Although reactions following inoculation with vaccinia virus were common in the recent population-wide vaccination programs [1], the biological basis for these adverse events (AEs) is not well understood. The performance of two independent clinical studies of a single vaccinia vaccine at our study site afforded us the unique opportunity to assess genetic factors that might predict systemic AEs. All of the vaccinia-naïve subjects enrolled developed pock formation at the vaccination site, and a subset experienced systemic reactions including fever, rash or regional lymphadenopathy. Since poxviruses have evolved multiple mechanisms to evade host immune responses, such as targeting of primary innate immunity and manipulating intracellular signal transduction pathways [2], we questioned whether subjects encountering AEs exhibited unique genetic polymorphisms in these pathways that made them more susceptible to these reactions.

In earlier studies, we characterized humoral and cellular immune responses and outlined patterns of systemic cytokine expression following smallpox vaccination [3–8]. In the current report, we utilized data collected during two independent studies to identify stable genetic factors associated with AEs. Since many genetic association studies fail to replicate during subsequent studies, we sought to repeat the assessment on an additional study group [9,10]. Independent replication of the results of our first study with the second strengthens the plausibility of these genetic associations. An identical panel of candidate single-nucleotide polymorphisms (SNPs) was evaluated in each of the studies. Subjects with systemic AEs including fever, lymphadenopathy, or generalized acneiform rash, were compared with those who did not experience these reactions. For both studies, the data were genotypes at 1442 SNPs across at least 386 candidate genes. This investigation provides important preliminary findings in two independent data sets addressing the contribution of common genetic variants to a complex clinical phenotype, which also bears substantial importance with respect to public health.

METHODS

Study Subjects

Vaccines, study subjects, and study design for both of the clinical trials have been described previously in detail. Both trials were conducted at Vanderbilt University in the NIH-funded

Vaccine and Treatment Evaluation Unit (VTEU) [4,8,11]. The first study [7] enrolled 85 healthy vaccinia-naïve adults in genotyping studies and the second study [11] also enrolled 46 healthy vaccinia-naïve adults. In both studies, individuals were asked to self-identify ethnic background. Both studies complied with the Internal Review Board policies of Vanderbilt and the NIH, and written consent was obtained for all individuals.

Clinical Assessments

For both studies, the same team of trained physicians and nurses used the same forms to obtain medical history and to record local and systemic AEs after vaccination. Subjects were examined at regular intervals (days 3–5, 6–8, 9–11, 12–15, and 26–30 after vaccination). Local and systemic AEs were recorded. Subjects with an oral temperature of greater than 38.3 °C anytime during the study, generalized skin eruptions on non-contiguous areas to the site of vaccination [11], or enlarged or tender regional lymph nodes associated with vaccination were defined as those experiencing systemic AEs.

Identification of Genetic Polymorphisms

We used a previously described custom SNP panel based on the NCI SNP500 Cancer project [12]; specifically, this panel targets investigation of soluble factor mediators and signaling pathways, many of which have known immunological significance [13]. There is a heavy weighting towards non-synonymous SNPs in this panel (*i.e.*, those that result in an amino acid substitution). Genotyping for single nucleotide polymorphisms (SNPs) was performed using DNA amplified directly from EBV-transformed B cells generated from peripheral blood samples collected from each subject. Genotyping was performed at the Core Genotyping Facility of the National Cancer Institute (NCI) in Gaithersburg, MD. Genotypes were generated using the Illumina™ GoldenGate assay technology. Of the 1536 SNPs assayed, a total of 1442 genotypes passed quality control filters for both the first and second sample sets. A complete list of the SNPs examined in this study is found in Supplemental Table 1.

Statistical Analysis

Demographic characteristics including age, gender, and race were compared between the first and second study using Student's t-test (for age) and two-sample tests of proportions (for AE status, gender, and race). Allele frequencies were estimated from the total number of copies of individual alleles divided by the number of all alleles in the sample, and compared between the two studies using a two-sample test of proportions. Deviations in the fitness for Hardy-Weinberg proportion were evaluated using the exact test described in Wigginton *et al* [14].

We chose a two-stage design for identifying and replicating genetic associations in the independent clinical trials. This study design was selected with the goal of minimizing Type I errors (false positives). For comparison, we also performed the genetic association analysis in a single pooled sample. In the first study, potential associations were tested between each of the 1442 SNPs passing quality control filters and the occurrence of AEs using logistic regression. For each SNP in the first sample set, we recorded the odds ratio estimate and p-value of the likelihood ratio test for a univariate logistic model. No correction for multiple comparisons was made in our first set, because we reserved the second study sample set for determination of probable true positives. In the second sample set, we tested only those SNPs having an AE-associated p-value ≤ 0.05 in the first study. We considered a significant SNP association in the first study to have replicated if it met the following criteria in the second study: an odds ratio that consistently associated AE risk with the same genotypes and a p-value ≤ 0.05. To obtain an empirical probability of meeting our replication criteria purely by chance, we generated 1,000 simulated data sets from both study sample sets by permuting case-control labels. An additional association with p-value 0.06 is discussed below because of its high biologic plausibility.

Patterns of linkage disequilibrium (LD) between replicated SNPs on the same chromosome were assessed using Haploview [15]. Haplotypes were inferred for SNPs in high LD using the iterative approach described in Lake *et al* [16]. The resulting haplotypes were tested for association with AEs using univariate logistic models. Statistical analyses and simulations were performed using R version 2.5.1, Stata version 9 (Stata Corp, College Station, TX), and Haploview version 3.32 [15,17,18].

RESULTS

Demographic Characteristics of Subjects Included in Genetic Analysis

In both studies, all participants were invited to donate genetic samples. In the first study, of the 148 vaccinia-naïve participants enrolled in the clinical trial, a total of 96 individuals gave consent for the genetic substudy. Of those 96 subjects with genetic data, 16 experienced *systemic* AEs following immunization. An additional 11 genotyped subjects who reported only a localized rash near the inoculation site were removed from the analysis to focus only on systemic AEs. The other 69 reporting no AEs were used as controls. Thus the first study included analysis of 85 subjects. In the second study, which included 48 vaccinia-naïve healthy adults, 46 gave consent for genotyping and were enrolled. Of the 46 individuals, 24 experienced systemic AEs.

Table 1 summarizes age, race, gender, and AE status decompositions of both studies. Table 1 also describes the results of the demographic comparisons between the first and second studies. As the table indicates, there was no statistical difference in age, gender, or race between the two study populations. In the first study, 40 (47%) individuals were male, 84 (99%) were white and 1 (1%) was Asian. In the second study, 27 (59%) individuals were male, 44 (96%) were white, 1 (2%) was black, and 1 (2%) was Asian.

Genetic Associations with Adverse Events

A total of 36 SNPs (within 26 genes) that showed significant associations in the first study were tested for potential associations in the second study. Three variant genotypes were confirmed to be associated with AEs in the second study. These included one SNP in *MTHFR* ($p < 0.01$) and two SNPs in *IRF1* ($p = 0.03$). The strong significance of the association in the replication study suggested a high level of plausibility that the gene products were involved in the pathogenesis of the AEs. The results of our simulation study indicated that the probability of meeting our replication criteria (an odds ratio that consistently associated AE risk with the same genotypes and a p-value ≤ 0.05) entirely by chance was $p < 0.001$. It is important to note that we also reanalyzed the data as a single pooled sample and found the same pattern of statistically significant associations. The statistical results that replicated in the second study are shown alongside those from the first study in Table 2.

Three SNPs in a third gene, *IL4*, had p-values equal to 0.06 in the second study. While not significant using a strict requirement for $p \leq 0.05$, we thought this association of great interest because of the prior biologic studies showing a central role for this cytokine in poxvirus biology [19–21]. Considering the reduced size of the second sample and the fact that the AE risk associated with variant genotypes was consistent across studies, these *IL4* SNPs warrant further study, because additional variants in linkage disequilibrium could also be associated with AE outcomes (Table 3).

The SNPs located in *IRF1* and *IL4* are located in the same chromosomal region (5q31.1), suggesting an indirect association with one or more functional variants in that region. Because of the close physical proximity of the associated variants in the two genes, Haploview [15] software was used to examine the patterns of LD among those variants in each sample. Figure

1 shows that the LD plots for SNPs in the two genes follow the same pattern in each study sample. While there is strong LD between SNPs within the two genes, there is little evidence for LD between the two genes, indicating that the associations for each gene are statistically separate signals.

This region of chromosome 5q31 contains discrete haplotype blocks [22]. Accordingly, haplotypes were inferred for AE-associated SNPs in *IRF1* (rs839 and rs9282763) and *IL4* (rs2070874, rs2243268, rs2243290). In both studies, two *IRF1* haplotypes accounted for all subjects. The common *IRF1* haplotype listed in Table 4 represented 71% of the first sample set and 63% of the second sample set. The rare *IRF1* haplotype was significantly associated with AEs in both studies ($p = 0.03$). Across both studies, two different three-SNP haplotypes in *IL4* accounted for 99% of subjects. The common *IL4* haplotype listed in Table 4 represented 78% of the first set and 87% of the second set. The rare *IL4* haplotype was significantly associated with risk of AEs in the first study ($p = 0.05$); the association was similar in the second study ($p = 0.06$).

DISCUSSION

The candidate genes identified with the strongest association with AEs in both studies include a metabolism gene previously associated with adverse reactions to a variety of pharmacologic agents (*MTHFR*) and an immunological transcription factor (*IRF1*). The statistical results from these studies have strong biological plausibility and are in agreement with previous work on the immune response to poxviruses.

MTHFR

A SNP in the 5,10-methylenetetrahydrofolate reductase (*MTHFR*) gene (rs1801133) was associated strongly with AE risk in both studies. This non-synonymous SNP in exon 5 causes an amino acid change from alanine to valine, and functional characterization of this SNP demonstrated that it is thermolabile and affects both the quantity and activity of the MTHFR enzyme [23]. The enzyme catalyzes the conversion of 5,10-methylenetetrahydrofolate to 5-methyltetrahydrofolate, which is a co-substrate for homocysteine remethylation to methionine. *MTHFR* function provides pools of methyl groups that are crucial for the control of DNA synthesis and repair mechanisms [24]. *MTHFR* is a key enzyme in homocysteine metabolism, which plays a major role in regulating endothelial function. It may be of interest in the future to examine the association of genetic variation in this gene with the rare cardiac events that occur after vaccination.

Genetic variation of *MTHFR* has been associated with a range of clinical outcomes, including altered cardiovascular function, organ transplantation, toxicity of immunosuppressive drugs, and systemic inflammation [25–28]. Elevated plasma homocysteine levels stimulate endothelial inflammatory responses, which could contribute to systemic AEs. Alternatively, since vaccination elicits immune responses involving the rapid proliferation of cells, demand for DNA synthesis metabolites would be elevated, and alterations in the level or activity of *MTHFR* enzyme may exert significant influence over this process.

Interferon regulatory factor-1

The interferon regulatory factor-1 (*IRF1*) gene is part of the immunological gene cluster on chromosome 5q31. We found two SNPs in *IRF1* that are significantly associated with AEs in both study samples. The *IRF1* gene encodes an important member of the interferon regulatory transcription factor (IRF) family. The IRF family regulates interferons and interferon-inducible genes. *IRF1* activates transcription of the Type I interferons α and β as well as genes induced

by the Type II interferon γ [29]. Many viruses target IRFs to evade host immune responses by binding to cellular IRFs and blocking transcriptional activation of IRF targets [30].

Polymorphisms in the gene coding for a transcription factor with such far-reaching effects as *IRF1* could have profound effects on the proper immune response and clearance of vaccinia virus. Mice deficient in interferon receptors are especially susceptible to vaccinia virus infection, suggesting an important role for these molecules in controlling vaccinia infection [31]. Vaccinia dedicates several host modifying genes to counteracting interferons. For example, the viral gene B18R encodes a protein that serves as a viral IFN-α/β binding protein that binds interferons from several species [32]. This protein also can bind to the cell surface after secretion, thus preventing host interferon from binding to cellular interferon receptors [33]. Although the SNPs identified in *IRF1* and *IL4* do not change amino acids in the encoded proteins, recent evidence suggests that synonymous SNPs, such as rs839, can alter regulation of mRNA or splice junctions [34,35]. It is also plausible that one or both SNPs are in LD with the causal variant not tested in this study.

Interleukin-4

Genetic polymorphisms in this major cytokine gene involved in adaptive immunity to viruses also may be associated with AEs, however with a p-value of 0.06 in our relatively small replication study. We found three SNPs in *IL4* that may be associated with AEs in both studies. There was high intragenic LD ($r^2 > 0.9$) between the tested SNPs within each gene, *IRF1* and *IL4*, and haplotypes inferred separately for each of these genes mirrored the significant risk patterns of the SNPs observed individually. Thus, the fact that multiple SNPs in high LD were identified in regions of *IRF1* and *IL4* strongly suggest that there are additional markers in LD, several of which could functionally contribute to the risk for AEs.

The *IL4* gene encodes a pleiotropic cytokine produced by a variety of immune cells, especially activated T cells. *IL4* controls humoral immune responses, isotype switching, and suppression of cytotoxic T cell function and expansion. Thus, genetic polymorphisms related to inappropriate regulation of *IL4* expression and/or activity of IL-4 cytokine could be associated with over-stimulated inflammatory responses leading to the development of clinical AEs. Previous studies on the role of *IL4* in poxvirus pathogenesis have shown it to have a central role in altering the adaptive immune response. *IL4* over-expression during infection with recombinant poxviruses encoding *IL4* suppresses the induction of cytotoxic T cell activity by inhibiting CD8+ T cell proliferation, which increased the pathogenicity of such recombinant viruses even in previously immunized animals [36]. *IL4* also plays a role in preventing optimum innate immune responses to poxviruses. IL-4 secretion during vaccinia virus infection of individuals with atopic dermatitis alters the cytokine milieu, resulting in a block of production of the antimicrobial peptide LL-37, accounting in part for the increased risk of vaccinia virus infection in subjects with atopic dermatitis [37].

Model of pathogenesis

Since the outcome of interest here was the aggregation of specific AEs, it is logical that more than one gene may be involved. The genes with variants for which we discovered an association with AEs are all potentially involved in pathways that are in line with our previously hypothesized mechanism of AEs involving excess stimulation of inflammatory pathways and the imbalance of tissue damage repair pathways. This model was developed from studies of circulating cytokines and relevant immunological effector cells [3–5]. For subjects experiencing AEs, vaccination appears to trigger an acute inflammatory response that is excessive. Antigen presentation to T cells in the dermis leads to the release of T-cell cytokines that trigger a cascade of cytokines and chemokines whose release enhances the inflammatory response by promoting the migration of monocytes into the lesion and their maturation into

macrophages and by further attracting T cells [38,39]. Taken together, these previous findings suggest that systemic AEs following smallpox vaccination may be consistent with low-grade macrophage activation syndrome caused by virus replication and vigorous tissue injury and repair.

There are limitations to this study. The subject numbers are small for a genetic association study of low-penetrance high-frequency alleles. The association of the *IL4* variations with AEs was weaker than that of the other genes. Nevertheless, findings of the same variants in two independent clinical trials, the high biologic plausibility of these associations in light of what is known about poxvirus biology, and the potential public health significance suggest the findings are of interest.

Conclusions and Future Directions

These data present the rare opportunity to study two independent cohorts of smallpox vaccinees relating common genetic variation to the occurrence of post-vaccination AEs. Statistical analysis of the first study revealed potentially significant associations between SNPs in biologically interesting candidate genes. Of the AE-associated genes identified in the first study, two replicated in an independent study, with one additional candidate gene just beyond our statistical significance cut-off but with a high level of biologic plausibility. It is possible that our findings could be due to chance, but we avoided multiple testing issues by testing only the most promising results in the validation sample. While all SNPs were tested in the first study, only those SNPs significantly associated with AEs were tested in the second study, and our empirically derived probability of replication by chance alone was less than 0.1%. The association of SNPs in three genes across both studies and their biologically plausible connection with AEs lends credence to the reproducibility of these associations.

As with any statistical association, follow-up studies are needed to identify the particular genetic susceptibility variants and examine the functional consequences of polymorphisms in the AE-associated genes. Since we found multiple AE-associated SNPs in regions of *IRF1* and *IL4*, focused studies should be undertaken to characterize the genetic variability in these candidate regions. Indeed, haplotypes in *IRF* and *IL4* displayed altered susceptibility to a specific systemic AE (fever) after smallpox vaccination [40]. While the association of AEs with a non-synonymous polymorphism in the gene for *MTHFR* points toward functional significance of this SNP, fine mapping of this locus should determine whether this is indeed the case. For all three candidate genes, both follow-up replication and functional studies are needed to establish the plausibility of the association of common genetic polymorphisms with the hypothesized etiological pathways.

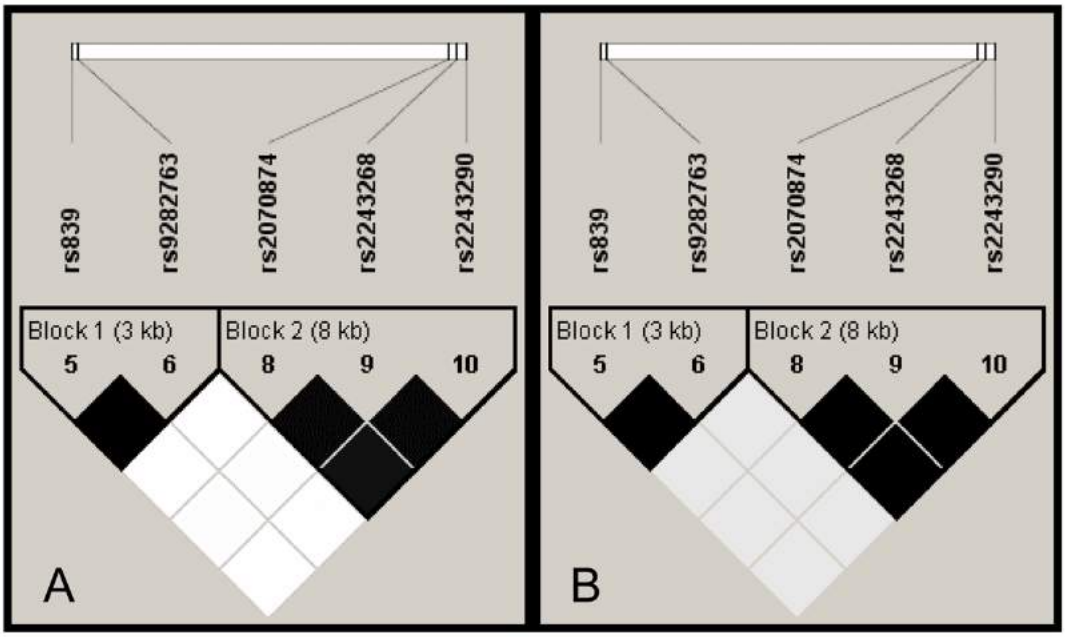

Figure 1. Haploview plot of SNPs at chromosome 5q31.1

Panel A =first study; panel B =second study. Squares are shaded to indicate strength of evidence for LD between the pairwise markers. Dark = strong evidence ($r^2 > 0.90$), light gray = weak evidence ($r^2 < 0.10$), white = no evidence ($r^2 < 0.0$). The same two LD blocks are apparent in both studies, encompassing SNPs in *IRF1* (rs839 and rs9282763) or *IL4* (rs2070874, rs2243268, and rs2243290).

Table 1

Summary of AE status, age, gender, and race for both studies.

Dataset	AE/nonAE	Age[a]	Gender (M/F)	Race (W/B/A)[b]
First study ($N = 85$)	16/69	23.2 (3.9)	40/45	84/0/1
Second study ($N = 46$)	24/22	24.2 (3.8)	27/19	44/1/1
[c] P-value of difference	< 0.01	0.15	0.20	0.25

[a] Mean (standard deviation)

[b] W = white, B = black, A = Asian

[c] Two-sided p-value for t-test (age) or two-sample test of proportions (AE/nonAE, gender, race)

Table 2

Genetic polymorphisms associated with AEs in both studies.

Gene	SNP (rs#)	SNP Location (Base pair) [a]	Chromosomal Location	First Study		Second Study

HYPERSENSITIVITY TO VACCINATION

The purpose of a vaccine is to induce immunity by means of the reaction of the immune system and for that reason its administration can give rise to certain undesired effects.

It should be remembered that all drugs, including vaccines, are not exempt to cause mild, moderate or serious adverse reactions during their administration. There are certain factors intrinsic to the product, genetic, immune and environmental factors that can interact with each other and, therefore, interfere in the individual response of each person with its administration.

Vaccines, unlike other medicines, are administered to healthy people with a preventive purpose and therefore it is necessary an optimum safety profile of the drug. In addition, it is important to know the precautions and contraindications of each vaccine in order to avoid risks in the vaccinated population.

Most of the adverse effects produced by vaccination are mild and transient, linked to local reactions that are limited to transient pain, swelling and/or redness in the area of administration.

The adverse reactions that can appear after the vaccination, are classified according to the WHO, in the following groups.

-Reactions induced by vaccination:

Local and systemic (fever, irritability, malaise, systemic symptoms, headache, arthralgia). These adverse reactions can be subdivided into common reactions that are usually mild, and rare that can be more serious (seizures, type I hypersensitivity reactions and II, neurological reactions, thrombocytopenia).

-Reactions due to defects in the quality of the vaccine:

Due to the intrinsic characteristics of the vaccine, the maintenance in optimal conditions of the preservatives, antibiotics and other substances that allow its stabilization.

-Reactions due to program errors (storage, transport, handling or administration)

-Reactions due to anxiety for the same act of vaccination:

Vasovagal syncope is described as a secondary reaction at the time or after the application, due to a feeling of fear to the application of an injectable.

In order to cope with this situation, there is an important educational, preventive and surveillance function. In addition, the knowledge of the intrinsic characteristics of the person, together with the genetic susceptibility of the same, can help in the resolution of these reactions, with their identification and anticipation, contributing the opportune measures in each moment.

Identifying the genetic factors associated with the adverse effects, would allow a screening and knowledge prior to the administration of vaccines, which could stratify and foresee the individual susceptible effects in order to optimize and resolve them.

Abstract

Background: Live vaccines have distinct safety profiles, potentially causing systemic reactions one to 2 weeks after administration. In the province of Ontario, Canada, live MMR vaccine is currently recommended at age 12 months and 18 months.

Methods: Using the self-controlled case series design we examined 271,495 12 month vaccinations and 184,312 18 month vaccinations to examine the relative incidence of the composite endpoint of emergency room visits or hospital admissions in consecutive one day intervals following vaccination. These were compared to a control period 20 to 28 days later. In a post-hoc analysis we examined the reasons for emergency room visits and the average acuity score at presentation for children during the at-risk period following the 12 month vaccine.

Results: Four to 12 days post 12 month vaccination, children had a 1.33 (1.29–1.38) increased relative incidence of the combined endpoint compared to the control period, or at least one event during the risk interval for every 168 children vaccinated. Ten to 12 days post 18 month vaccination, the relative incidence was 1.25 (95%, 1.17–1.33) which represented at least one excess event for every 730 children vaccinated. The primary reason for increased events was statistically significant elevations in emergency room visits following all vaccinations. There were non-significant increases in hospital admissions. There were an additional 20 febrile seizures for every 100,000 vaccinated at 12 months.

Conclusions: There are significantly elevated risks of primarily emergency room visits approximately one to two weeks following 12 and 18 month vaccination. Future studies should examine whether these events could be predicted or prevented.

Introduction

The measles, mumps and rubella (MMR) have been used extensively in children and have been demonstrated to be safe and effective in preventing disease [1]. However, because it is a live vaccine the MMR vaccine has the potential to cause adverse events one to 2 weeks following vaccination [2]. Most reactions to this vaccine will be mild with fevers occurring in 5 to 15% and rashes in 5% [3]. More serious reactions are extremely rare and may not be identified during pre-licensure trials [4]. Post market surveillance has identified an incidence of febrile seizures following the MMR vaccine of 25 to 34 per 100 000 vaccinated and a two to three-fold increased relative risk [5,6]. However, at a population level, mass exposures to a vaccine with a rare side effect profile could have detectable important population level effects. No study has examined the impact on aggregate health service utilization following the MMR vaccination.

In the province of Ontario, Canada, the MMR and meningococcal C vaccines are currently recommended at 12 months of age and a second dose of MMR vaccine along with a booster dose of pentavalent (diphtheria, acellular pertussis, tetanus, polio and *Haemophilus influenzae* type b) vaccine is recommended at 18 months of age. We sought to examine the population wide effects of these

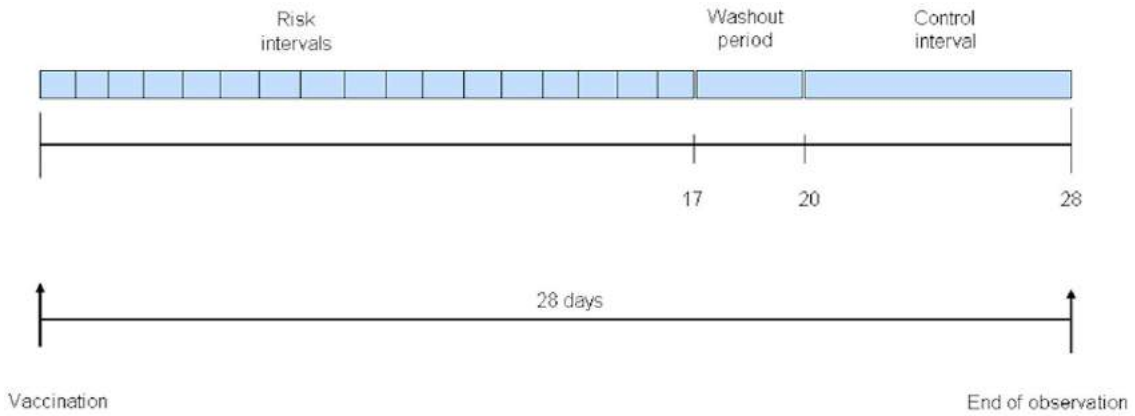

Figure 1. Illustration of the self-controlled case series design. The observation period for each patient begins with pediatric vaccination date (leftmost upward arrow) and continues for a total of 28 days. In the primary analyses, each day post vaccination is considered a *risk interval*, and consecutive days with a statistically significant t elevation in relative incidence were pooled to create a combined risk interval. Days 20–28 comprise the *control interval*. The intervening days represent the wash-out period.
doi:10.1371/journal.pone.0027897.g001

vaccinations on the combined endpoint of emergency room visits and hospital admissions in selected periods post-vaccination.

Methods

Design

The overall goal of this study was to determine the risk of serious adverse events in all children vaccinated in Ontario at 12 and 18 months of age with recommended pediatric vaccines. This was measured by comparing the risk of either presentation to emergency room (ER), or hospital admission in consecutive one day periods after the date of vaccination compared to a later control period. This analysis was conducted on all children born between April 1st 2006 and March 31st 2009. Our primary analysis of the composite risk of ER visits and hospitalizations was conducted using the *self-controlled case-series design*, described by

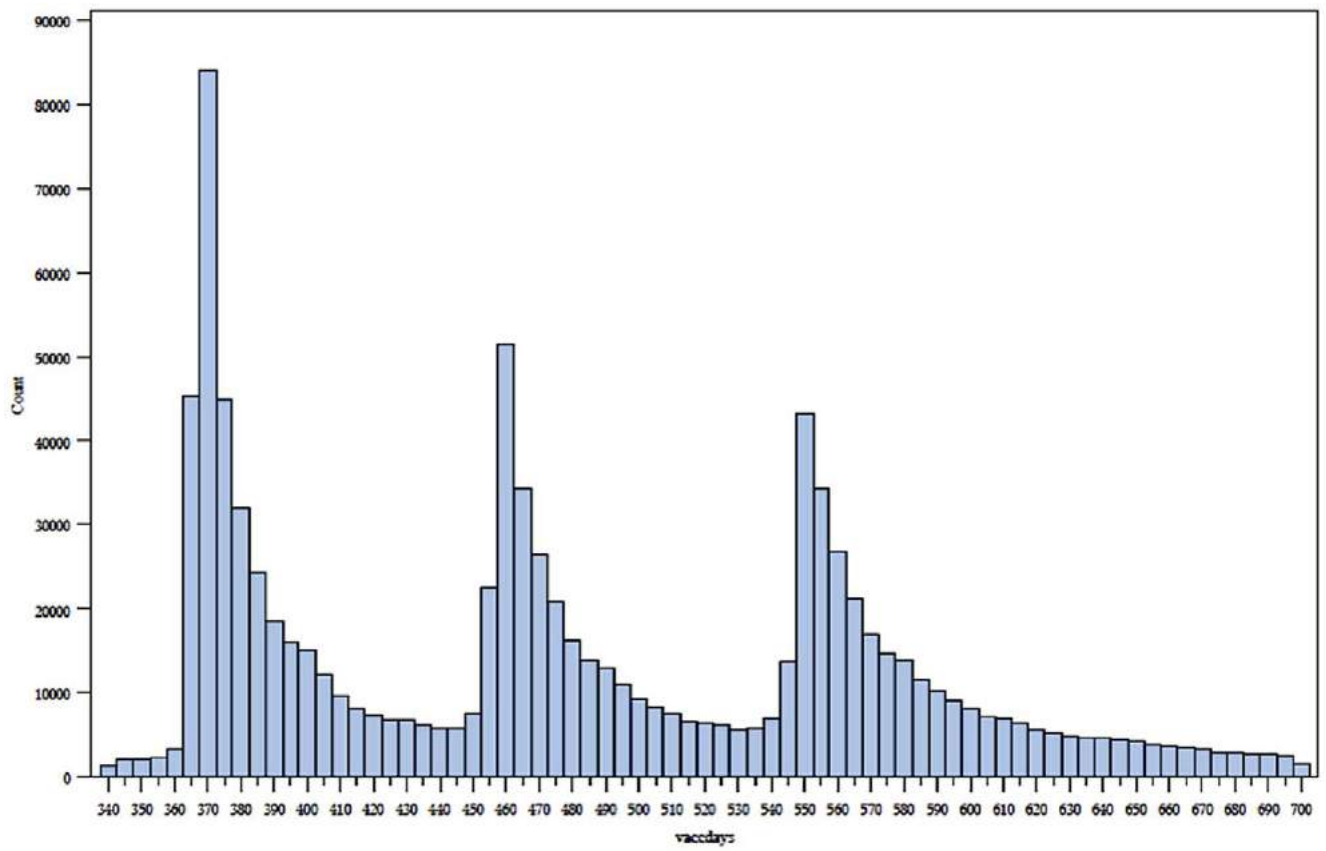

Figure 2. Vaccination events by days since birth from days 340 to 700. Count = number of individuals vaccinated on a given day. **Days** = number of days after date of birth.
doi:10.1371/journal.pone.0027897.g002

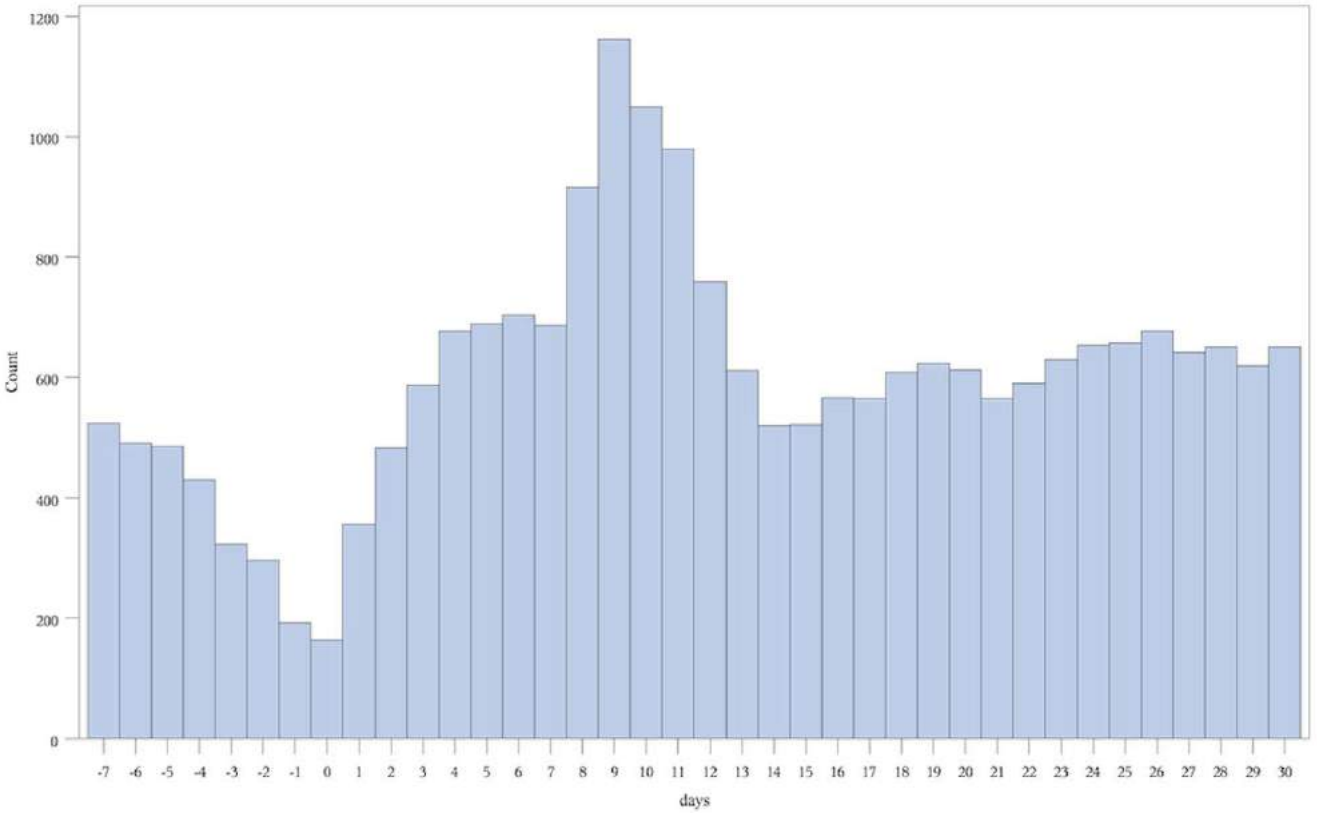

Figure 3. Number of combined endpoints versus days before/after 12 month vaccination. Count = number of combined endpoints of emergency room visit or hospitalization. **Days** = number of days before or after vaccination, day 0 being the day of vaccination.

Farrington and associates [7,8]. We analyzed events following the 12 and 18 month vaccinations separately.

Data

Our study cohort included all children in the Newborn Screening Ontario data set between April 1st 2006 and March 31st 2009. This database captures over 99% of Ontario births. Our exposure of interest, pediatric vaccination, was identified using the Ontario Health Insurance Plan (OHIP) database. We used codes for general vaccination, as, except for influenza, vaccine-specific codes are not available. To identify the 12 and 18 month vaccinations separately we identified vaccination occurring on exactly the respective due dates as well as vaccinations occurring up to 60 days after the respective date. To allow adequate follow-up after the 12 month vaccination, only vaccinated children born on or before December 31st 2008 could be included in the analysis (N = 271,495 children). Likewise, only vaccinated children born on or before June 30th 2008 could be included in the analysis of adverse events after the 18 month vaccination (N = 184,312 children). Only subjects with both vaccinations and events in the observation period contribute to the conditional self-controlled case series analysis, therefore infants with no ER visits or hospitalizations in close proximity to the vaccination were not included. If infants had more than one vaccination in the database during the two month target period the first vaccination was used as the index vaccination. If another vaccination occurred within the observation period (0 to 28 days after the index vaccination), or the infant died, then this individual was excluded from analysis (see Appendix S1).

The Canadian Institute for Health Information's (CIHI) Discharge Abstract Database (DAD) captures all hospital admissions, including children in both tertiary and community hospitals, and was used to ascertain hospital admission. CIHI's National Ambulatory Care Registration System (NACRS) was used to ascertain ER visits, the Canadian Triage and Acuity Score (CTAS) rating and the diagnosis made by the most responsible physician for the visit. The Registered Persons Database was used to ascertain cases of death. These datasets are housed at the Institute for Clinical Evaluative Sciences (ICES), and linkage between datasets was achieved using encrypted health card numbers as unique identifiers. The study was performed within ICES' status as a Prescribed Entity in Ontario's privacy legislation and Research Ethics Board approval was received at OHRI and ICES (Sunnybrook).

Analysis

We graphed the number of combined endpoint events in the days before and after vaccination. In the self-controlled case series model, the date of vaccination serves as the index date for exposure for each patient. Previous studies have identified that children are at increased risk for systemic reactions at different times from 5–14 days after vaccination [5,6,9,10]. Because *a priori* we did not know with certainty the time period following vaccination for which there would be an increased risk of our combined endpoint, we modified the standard self-controlled case series approach by looking for an elevation in risk during each post-vaccination day up to day 17 (Figure 1). We then classified days 20–28 as unexposed, establishing a washout period in

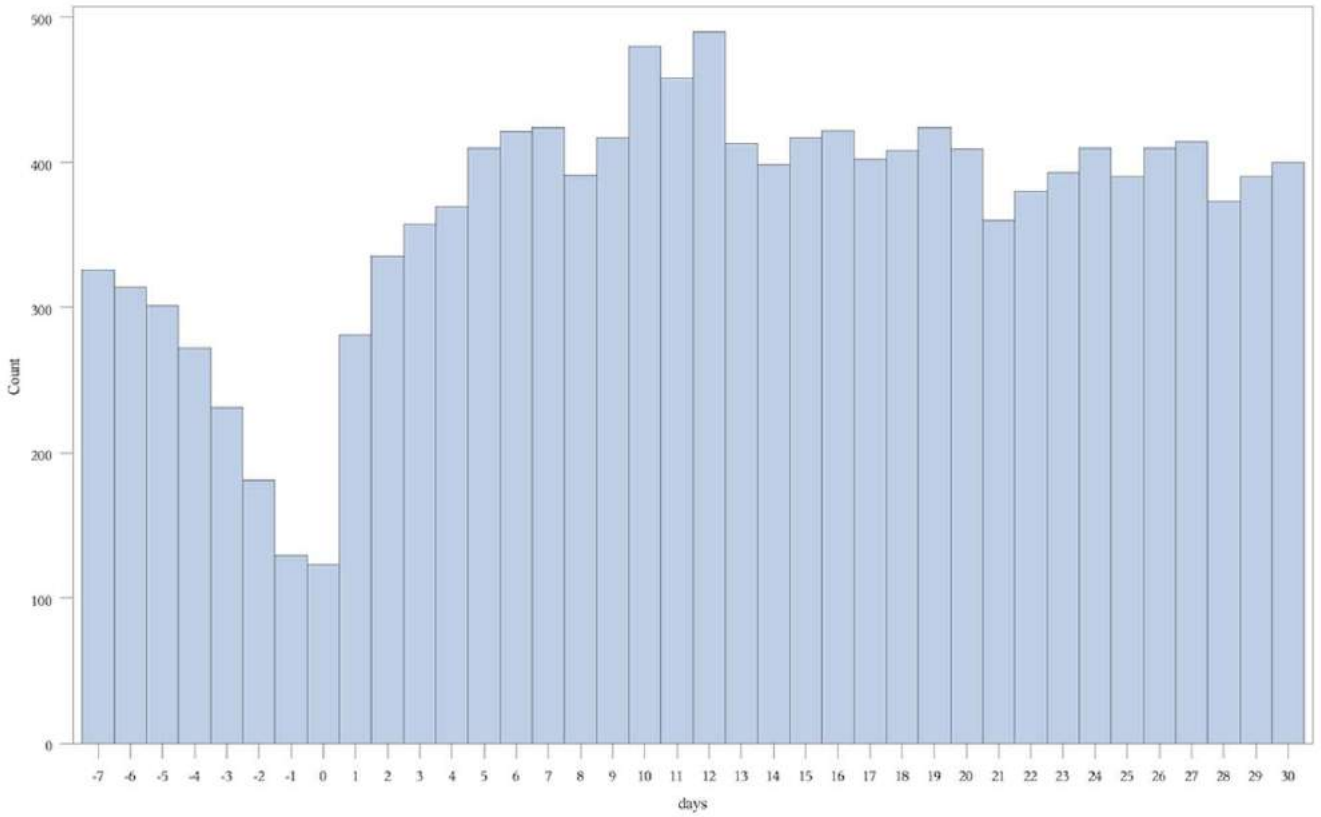

Figure 4. Number of combined endpoints versus days before/after 18 month vaccination. Count = number of combined endpoints of emergency room visit or hospitalization. **Days** = number of days before or after vaccination, day 0 being the day of vaccination.
doi:10.1371/journal.pone.0027897.g004

between the exposed and unexposed periods (Figure 1). When multiple events occurred to a given individual, the first occurrence of the composite outcome in the post-vaccination period was used (eg., someone attending the ER who was then admitted would have one event counted in that period). The relative incidence rate of the composite endpoint during the exposed period compared with the unexposed period was analyzed using a fixed effects Poisson regression model. This model included a term for exposure period and a term for patient, thereby allowing each individual to serve as his or her own control and accounting for intra-individual correlation. An offset term was also included to account for the differing durations of the exposed and unexposed periods. Deaths after the 12 and 18 month vaccinations were explored in a separate analysis due to the fact that a subject dying effectively truncates their follow-up potentially biasing the results of the SCCS analysis. As noted above, children who died during the follow-up period were excluded from the SCCS analysis of ER visits and hospitalizations.

To define the at-risk period we combined consecutive days with statistically significant elevations in relative incidence. We considered statistical significance to be a p-value less than or equal to 0.001 based on a Bonferroni correction to account for multiple testing (38 separate tests) [11]. We conducted separate analyses for the 12 and 18 month vaccinations. We also conducted secondary analyses to determine the association between vaccination and ER visits, hospital admissions, and deaths separately. All p values were 2 sided, and analyses were conducted using SAS version 9.2 (SAS Institute, Cary, NC).

In order to assess the types of cases captured by our endpoints we conducted a post-hoc analysis where we compiled the reasons for presentation to the ER as determined by the most responsible physician for the risk period for the 12 month vaccination. This was compared to the prevalence of the same diagnoses in the control period. We examined a tracer condition, ear/face nose injury, for which we do not expect a difference in rates. We also identified the CTAS ratings for presentations during the affected period and compared them to those during the control period using the Wilcoxon Rank-Sum test. CTAS ratings range from 1 to 5 with 1 representing a severe condition requiring resuscitation and 5 representing a less severe condition requiring non-urgent care [12]. In another post-hoc analysis we graphically examined the pattern of events following 12 and 18 month vaccination in the years 2002–2005 when the MMR vaccine was still given at 12 months, however, the booster was given at five years and not eighteen months.

Results

In total, we examined 455,807 separate vaccination events in these 413,957 children that occurred at 12 and 18 months plus 60 days (Figure 2). We present the number of endpoint events versus days pre and post vaccination graphically for each of the vaccine periods (Figures 3 and 4).

12 month analysis

271,495 children received vaccinations between 365 and 425 days of age. Consecutive statistically significant elevations in combined endpoints began on day 4 and continued to day 12. A

Table 1. Relative incidence of combined endpoint (hospital admission or emergency room visit) following 12 month vaccination.

Risk interval*	Endpoints during risk interval (n)	Relative Incidence (95% CI)	P value
Day 4	621	1.15 (1.06–1.25)	0.0008
Day 5	641	1.19 (1.10–1.29)	<0.0001
Day 6	647	1.20 (1.11–1.31)	<0.0001
Day 7	644	1.20 (1.10–1.30)	<0.0001
Day 8	870	1.62 (1.50–1.74)	<0.0001
Day 9	1096	2.04 (1.91–2.17)	<0.0001
Day 10	991	1.84 (1.72–1.97)	<0.0001
Day 11	923	1.72 (1.60–1.84))	<0.0001
Day 12	713	1.32 (1.22–1.43)	<0.0001
Days 4 to 12** (Combined risk interval)	6462	1.33(1.29–1.38)	<0.0001
Days 20–28 (Control Interval)	4845	NA	NA

*Risk and control intervals expressed as days following vaccination.
**Total number of endpoints in the combined risk interval are less than the cumulative individual day event total because some children may have experienced events in multiple days and only the first event is counted.
doi:10.1371/journal.pone.0027897.t001

total of 6462 children experienced at least one of the combined endpoints during the combined 9 day at risk period compared to 4845 during the 9 day control period. The relative incidence of the combined endpoint was 1.33 (1.29–1.38) (Table 1). The highest relative incidence during the at-risk period occurred between days 8 and 11 peaking at 2.04 (1.91–2.17) on day 9. Overall, an excess of 595 children experienced at least one of the combined endpoints during the risk interval per 100,000 vaccinated, or one additional child experiencing at least one endpoint during the risk interval for every 168 children who received their 12 month vaccinations (Table 2). Examining the historical graph of the events post 12 month vaccination in the years 2002–2005 demonstrated a similar peak in events (Figure 5).

The primary reason for the elevation in the combined endpoint was an increase in ER visits (relative incidence 1.34(1.29–1.39)). There were an excess of 598 children experiencing 1 or more ER visits during the risk interval per 100,000 vaccinations or 1 additional child for every 168 children vaccinated. There was no increase in hospital admissions (relative incidence 1.08 (0.93–1.25)). There were five or fewer deaths (Table 3). The average CTAS score for ER visits during the risk period was 3.27 compared to 3.26 for the control period. ($p = 0.74$), suggesting no differences in severity of presentation between ER visits in the risk and control periods. There was an increase in presentation for multiple conditions during the risk period compared to the control period. The largest relative risk was associated with febrile seizures (relative incidence = 2.34, fever (RI = 2.31) and viral exanthem (RI = 2.23). We calculated that there were approximately 20 additional febrile seizures during the risk interval for every 100 000 children vaccinated. There was no increase in our tracer condition (ear/face/nose injury).

18 month analysis

184,312 children received vaccinations between 545 and 605 days of age. Consecutive statistically significant elevations in combined endpoints began on day 10 and continued to day 12. A total of 1275 children experienced at least one event included in the combined endpoint during the combined three day at risk period compared to 3065 during the nine day control period. The relative incidence of the combined endpoint was 1.25 (1.17–1.33) (Table 4). The highest relative incidence during the at-risk period was 1.34 (1.21–1.47) which occurred on day 12. Overall, an additional 137 children experienced at least one combined endpoint during the three day risk period per 100,000 vaccinated, or one additional child experiencing at least one excess event for every 730 children vaccinated (Table 3). Examining the historical graph of the events post 18 month vaccination in the years 2002–2005, when the booster dose of the MMR vaccine was not given, demonstrated no similar peak in events (Figure 5).

The primary reason for the elevation in the combined endpoint was an increase in ER visits (relative incidence 1.25(1.18–1.34)). There were an excess of 139 children experiencing one or more ER visits during the risk interval or one excess visit for every 719 children vaccinated. There was not a significant increase in hospital admissions (relative incidence 1.23(0.94–1.59)) (Table 4). No deaths occurred in the risk or control periods.

Discussion

Our analysis demonstrated that the 12 and 18 month vaccinations are not associated with an increase in adverse events immediately following vaccination. Instead it showed a reduced risk in this period, which is likely a result of the previously

Table 2. Increased risk of combined endpoints from vaccination.

Vaccination	Additional children experiencing at least one event (per 100,000 vaccinations)	Number vaccinated	Number vaccinated per excess event
12 months	595	271,495	168

documented healthy vaccinee effect [9,13,14]. We identified an increase in events occurring between 4 and 12 days post-vaccination for the 12 month and, to a lesser extent and for a shorter time period for the 18 month vaccines. The majority of these events represented ER visits and at their peak, on day 9 following the 12 month vaccine, were approximately twice the baseline rate. Although there was an increase in hospital admission in each period, none of these increases were statistically significant. Overall the increase in event rate following the 12 month vaccines accounted for approximately 598 extra children experiencing one or more ER visits during the risk interval per 100,000 vaccinations. The average acuity of patients presenting to the emergency room was similar to that in the control period. The conditions for which there were the largest increase in risk for presentation to the emergency room during the risk interval compared to the control interval following the 12 month vaccine were febrile convulsions, fever and viral exanthema, consistent with the known adverse event profile of MMR and varicella vaccines. There were 20 additional febrile seizures for every 100,000 children vaccinated at 12 months.

The development of an inflammatory response approximately one week after vaccination is recognized in the literature. For example, the Centres for Disease Control and Prevention list days 7 to 12 post vaccination as the highest risk period for developing fever and possibly a rash [15]. This closely coincides with our observation of the time period during which emergency room visits peaked. A previous twin study also identified the development of systemic symptoms between days 6 and 14 and peaking on day 10 [9]. A study of febrile seizures following MMR vaccination identified the highest at risk period to be 8 to 14 days following vaccination and a relative risk of 2.83 and other studies have made similar observations [5,6,16]. These are consistent with our findings. While it is known that vaccines can produce these adverse events, our study demonstrated the population wide impact of this effect and that these events are resulting in an increase in health services utilization. The estimated 595 additional children experiencing at least one event for every 100 000 vaccinated translates into approximately one child experiencing at least one event per 168 children vaccinated. The explanation for this effect is likely the controlled replication of the virus creating a mild form of the illness the vaccine is designed to prevent. The top diagnoses for the presentations to the emergency room during the 12 month risk interval would all be consistent with a mild viral illness.

The reduced effect at 18 months is likely due to this vaccination in most instances being a second exposure to the antigen to which the vast majority of children would have developed adequate immunity. Residual events during this period may represent the small percentage of children who did not immunologically respond to the first dose of the vaccine.

Our study has several strengths. The use of the self-controlled case series design allows for individuals to serve as their own controls implicitly controlling for all fixed covariates [8,17]. Seasonal confounding is unlikely to have influenced our findings since the 12 and 18th month vaccines are provided throughout the year. The potential for confounding due to co-existent exposures at 12 and 18 months exists, however, if such an exposure were to be significant we would have expected to observe an effect at 18 months in our historical analysis. Our study included nearly all children born in Ontario during the study period which strengthens the generalizability of these findings. The combination of the self-controlled case series design and our sample size increased the power of our study to identify small effects. While our study cannot establish causality it has many features that support a causal relationship between vaccination and delayed adverse events. These include the consistency with other studies and a compelling biological model which explains the diagnoses in the affected children and the reduction in effect with the 18 month vaccinations. Furthermore, our historical analysis demonstrates that the effect seen at 18 months after MMR vaccination in 2006–2009 is not present in 2002–2005, when the MMR vaccine was given only at 12 months and not at 18 months. The effect is still clearly visible after the 12 month vaccination in the 2002–2005 data.

There are important limitations of this study. The first is that, as mentioned, the healthy vaccinee effect may have masked an association in the immediate post-vaccination period. Second, we cannot know whether a specific vaccine was associated with the adverse events as multiple vaccines are typically administered at each visit. However, we have previously demonstrated the safety of the pentavalent vaccine which is given with the 18 month MMR vaccine [18]. It is possible that the effects seen at 12 month are in part due to the potential co-administration of the meningococcal C vaccine, however, this is not a live vaccine and should create inflammation in the immediate post-vaccination period as opposed to one week later. Third, the codes we used for identifying the reasons for presentation to the emergency room have not been validated. However, we would expect that the diagnoses of febrile convulsion to have a low misclassification error and has previously been validated as a useful ER code in a separate dataset [19]. We also did not look for increases in visits to physician offices that did not result in presentation to the emergency room or admission and cannot comment on the impact of immunization on that outcome.

Table 3. Relative incidences of individual endpoints (emergency room visit, hospital admission, death) during highest risk interval compared to control period.

Outcome	12 months	Events (risk/control)	18 months	Events (risk/control)
Emergency visits	1.34 (1.29–1.39)	6395/4772	1.25 (1.18–1.34)	1264/3024
Admissions	1.08 (0.93–1.25)	356/330	1.23 (0.94–1.59)	78/191
Deaths	-	< = 5/< = 5	-	0/0

doi:10.1371/journal.pone.0027897.t003

Table 4. Relative incidence of combined endpoint (hospital admission or emergency room visit) following 18 month vaccination.

Risk interval*	Endpoints during risk interval (n)	Relative Incidence (95% CI)	P value
Days 10	447	1.31 (1.19–1.45)	<0.0001
Days 11	428	1.26 (1.14–1.39)	<0.0001
Days 12	455	1.34 (1.21–1.47)	<0.0001

Our findings have important implications for those providing care to children. The immediate risk of a serious adverse event following immunization is low with both the vaccination visits that contain the MMR and varicella vaccines. However, the 12 month vaccines which typically contain the first dose of the MMR vaccine is associated with an increased risk of an emergency room visit approximately 4 to 12 days after immunization, peaking between days 8 and 11. This increase in rate of a child experiencing at least one event for every 158 vaccinated individuals is associated with a similar acuity as the control period. If the presentation to the emergency room was due to parental anxiety we would have expected to see a reduction in acuity during the risk period. The findings also suggest that the reactions are not severe since acuity was not higher than the control period and furthermore, there were few hospital admissions. Additional reassurance can be derived from previous studies that identified no long-term consequences related to vaccine associated febrile seizures [5,6]. The increase in ER visits we observed could be a result of insufficient information being provided to parents who may not expect their child to develop a reaction a week after vaccination. In particular, the likelihood of this risk may be underestimated by physicians. Our study also reinforces the reduced risk of events following the second dose of MMR vaccine.

Given the effectiveness of the MMR vaccine in eliminating both measles and rubella, and the highly infectious nature of these diseases, high vaccination coverage is essential. The diseases that the vaccines are preventing are not benign and vaccination can eliminate many of the serious sequelae of these infections [20]. Complications from measles include otitis media (7–9% of cases), pneumonia (1–6% of cases), encephalitis (1 per 1,000–2,000 cases), subacute sclerosing panecephalitis (1 per 100,000 cases), and death (1 per 3000 cases) [3,21]. Further studies attempting to predict which children develop post-vaccination reactions, as well as determining the effectiveness of prophylactic treatment with antipyrectics prior to the high risk period for symptom development are warranted.

Increased Risk of Noninfluenza Respiratory Virus Infections Associated With Receipt of Inactivated Influenza Vaccine

Benjamin J. Cowling,[1] Vicky J. Fang,[1] Hiroshi Nishiura,[1,2] Kwok-Hung Chan,[3] Sophia Ng,[1] Dennis K. M. Ip,[1] Susan S. Chiu,[4] Gabriel M. Leung,[1] and J. S. Malik Peiris[1,5]

[1]School of Public Health, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Pokfulam, Hong Kong SAR, China; [2]PRESTO, Japan Science and Technology Agency, Saitama; [3]Department of Microbiology, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Queen Mary Hospital, [4]Department of Pediatrics and Adolescent Medicine, The University of Hong Kong, Queen Mary Hospital, and [5]Centre for Influenza Research, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Pokfulam, Hong Kong SAR, China

We randomized 115 children to trivalent inactivated influenza vaccine (TIV) or placebo. Over the following 9 months, TIV recipients had an increased risk of virologically-confirmed non-influenza infections (relative risk: 4.40; 95% confidence interval: 1.31-14.8). Being protected against influenza, TIV recipients may lack temporary non-specific immunity that protected against other respiratory viruses.

Influenza vaccination is effective in preventing influenza virus infection and associated morbidity among school-aged children [1, 2]. The potential for temporary nonspecific immunity between respiratory viruses after an infection and consequent interference at the population level between epidemics of these viruses has been hypothesized, with limited empirical evidence to date, mainly from ecological studies [3–15]. We investigated the incidence of acute upper respiratory tract infections (URTIs) associated with virologically confirmed respiratory virus infections in a randomized controlled trial of influenza vaccination.

DOI: 10.1093/cid/cis307

METHODS

Recruitment and Follow-up of Participants

In a double-blind randomized controlled trial, we randomly allocated children aged 6–15 years to receive 2008–2009 seasonal trivalent influenza inactivated vaccine (TIV; 0.5 mL Vaxigrip; Sanofi Pasteur) or placebo [16]. Serum specimens were obtained from participants before vaccination from November through December 2008, a month after vaccination, in midstudy around April 2009, and at the end of the study from August through October 2009. Participants were followed up for illnesses through symptom diaries and telephone calls, and illness reports in any household member triggered home visits during which nasal and throat swab specimens (NTSs) were collected from all household members. We defined the follow-up period for each participant from 14 days after receipt of TIV or placebo to collection of midstudy serum samples as the winter season and from collection of midstudy samples through final serum sample obtainment as the summer season.

Proxy written informed consent was obtained for all participants from their parents or legal guardians, with additional written assent from those ≥8 years of age. The study protocol was approved by the Institutional Review Board of Hong Kong University.

Laboratory Methods

NTSs were tested for 19 respiratory viruses by the ResPlex II Plus multiplex array [17–19] and for influenza A and B by reverse-transcription polymerase chain reaction (RT-PCR) [16, 20] (Supplementary Appendix). We refer to infections determined by these assays as "confirmed" infections. Information on influenza serology is provided in the Supplementary Appendix .

Statistical Analysis

We defined an acute respiratory illness (ARI) determined by self-reported signs and symptoms as ≥2 of the following signs or symptoms: body temperature ≥37.8°C, headache, sore throat, cough, presence of phlegm, coryza, and myalgia [16]. We defined febrile acute respiratory illness (FARI) as body temperature ≥37.8°C plus cough or sore throat. Because duration of follow-up varied by participant, we estimated the incidence rates of ARI and FARI episodes and confirmed viral infections overall and during the winter and summer seasons and estimated the relative risk of these episodes for participants who received TIV versus placebo with use of the incidence rate ratio using Poisson regression (Supplementary

Table 1. Characteristics of Participants and Duration of Follow-up

Characteristic	TIV (n = 69)	Placebo (n = 46)
Age group, No. (%)		
6–8 years	19 (28)	16 (35)
9–11 years	41 (59)	27 (59)
12–15 years	9 (13)	3 (7)
Female sex, No. (%)	30 (43)	23 (50)
Median duration of follow-up, days	272	272
Mean no. of individuals per household	3.7	3.6

Abbreviation: TIV, trivalent inactivated influenza vaccine.

Appendix). All statistical analyses were conducted using R, version 2.11.0 (R Development Core Team, Vienna, Austria). Data and syntax to reproduce these statistical analyses are available on the corresponding author's Web site.

RESULTS

Among the 115 participants who were followed up, the median duration of follow-up was 272 days (interquartile range, 264–285 days), with no statistically significant differences in age, sex, household size, or duration of follow-up between TIV and placebo recipients (Table 1). We identified 134 ARI episodes, of which 49 met the more stringent FARI case definition. Illnesses occurred throughout the study period (Supplementary Appendix Figure 1). There was no statistically significant difference in the risk of ARI or FARI between participants who received TIV and those who received placebo, either during winter or summer 2009 (Table 2).

We were able to collect 73 NTSs for testing from participants for 65 of 134 (49%) ARI episodes, which included 22 of 49 (45%) FARI episodes. The mean delay between ARI onset and collection of first NTS was 1.22 days, and 5% of NTSs were collected >3 days after illness onset, with no statistically significant differences between TIV and placebo recipients. We detected respiratory viruses in 32 of 65 NTSs (49%) collected during ARI episodes, which included 12 of 22 (55%) FARI episodes. We collected 85 NTSs from participants at times when one of their household contacts reported an acute URTI but the participants were not ill, and identified viruses in 3 of the specimens (4%), including influenza A (H3N2), coxsackie/echovirus, and coronavirus 229E.

There was no statistically significant difference in the risk of confirmed seasonal influenza infection between recipients of TIV or placebo, although the point estimate was consistent with protection in TIV recipients (relative risk [RR], 0.66; 95% confidence interval [CI], .13–3.27). TIV recipients had significantly lower risk of seasonal influenza infection based on serologic evidence (Supplementary Appendix). However, participants who received TIV had higher risk of ARI associated with confirmed noninfluenza respiratory virus infection (RR, 4.40; 95% CI, 1.31–14.8). Including 2 additional confirmed infections when participants did not report ARI, TIV recipients had higher risk of confirmed noninfluenza respiratory virus infection (RR, 3.46; 95% CI, 1.19–10.1). The majority of the noninfluenza respiratory virus detections were rhinoviruses and coxsackie/echoviruses, and the increased risk among TIV recipients was also statistically significant for these viruses (Table 3). Most respiratory virus detections occurred in March 2009, shortly after a period of peak seasonal influenza activity in February 2009 (Figure 1).

Table 2. Incidence Rates of Acute Upper Respiratory Tract Infection Among 115 Participants Aged 6–15 Years Who Received Trivalent Inactivated Influenza Vaccine or Placebo

	TIV (n = 69)		Placebo (n = 46)			
Variable	Rate[a]	(95% CI)	Rate[a]	(95% CI)	Relative Risk (95% CI)	*P* Value
Winter 2009						
ARI[b] episodes	2080	(1530–2830)	2260	(1550–3300)	0.92 (.57–1.50)	.74
FARI[b] episodes	609	(346–1070)	753	(392–1450)	0.81 (.34–1.92)	.63
Summer 2009						
ARI[b] episodes	1510	(1130–2020)	1160	(757–1780)	1.30 (.78–2.18)	.31
FARI[b] episodes	658	(424–1020)	442	(221–884)	1.49 (.65–3.38)	.33

Abbreviations: ARI, acute respiratory illness; CI, confidence interval; FARI , febrile acute respiratory illness; TIV, trivalent inactivated influenza vaccine.

[a] Incidence rates were estimated as the number of ARI or FARI episodes per 1000 person-years of follow-up.

[b] ARI was defined as at least 2 of the following symptoms: body temperature ≥37.8°C, cough, sore throat, headache, runny nose, phlegm, and myalgia; FARI was defined as body temperature ≥37.8°C plus cough or sore throat.

Table 3. Incidence Rates of Respiratory Virus Detection by Reverse-Transcription Polymerase Chain Reaction and Multiplex Assay

	TIV (n = 69)			Placebo (n = 46)			
Variable	No.	Rate[a]	(95% CI)	No.	Rate[a]	(95% CI)	*P* Value
Any seasonal influenza	3	58	(19–180)	3	88	(28–270)	.61
Seasonal influenza A (H1N1)	2	39	(10–160)	2	59	(15–240)	.68
Seasonal influenza A (H3N2)	1	19	(3–140)	0	0	(0–88)	.31
Seasonal influenza B	0	0	(0–58)	1	29	(4–210)	.17
Pandemic influenza A (H1N1)	3	58	(19–180)	0	0	(0–88)	.08
Any noninfluenza virus[b]	20	390	(250–600)	3	88	(28–270)	<.01
Rhinovirus	12	230	(130–410)	2	59	(15–240)	.04
Coxsackie/echovirus	8	160	(78–310)	0	0	(0–88)	<.01
Other respiratory virus[c]	5	97	(40–230)	1	29	(4–210)	.22
ARI episode with specimen collected but no virus detected	19	369	(235–578)	14	412	(244–696)	.75
ARI episode with no specimen collected	41	796	(586–1080)	28	824	(569–1190)	.89

Incidence rates are from respiratory specimens collected from 115 participants aged 6–15 years who received trivalent influenza vaccine or placebo during 134 acute respiratory illness episodes.

Abbreviations: ARI, acute respiratory illness; CI, confidence interval; TIV, trivalent inactivated influenza vaccine.

[a] Incidence rates were estimated as the no. of virus detections or illness episodes per 1000 person-years of follow-up. ARI was defined as at least 2 of the following symptoms: body temperature ≥37.8°C, cough, sore throat, headache, runny nose, phlegm, and myalgia.

[b] In TIV recipients there were 4 detections with both rhinovirus and coxsackie/echovirus, and 1 detection with both coxsackie/echovirus and coronavirus NL63.

[c] Including positive detections of coronavirus, human metapneumovirus, parainfluenza, respiratory syncytial virus (RSV). The ResPlex II multiplex array tested for 19 virus targets including influenza types A and B (including 2009-H1N1), RSV types A and B, parainfluenza types 1–4, metapneumovirus, rhinovirus, coxsackievirus/echovirus, adenovirus types B and E, bocavirus, and coronavirus types NL63, HKU1, 229E, and OC43.

DISCUSSION

In the prepandemic period of our study, we did not observe a statistically significant reduction in confirmed seasonal influenza virus infections in the TIV recipients (Table 3), although serological evidence (Supplementary Appendix) and point estimates of vaccine efficacy based on confirmed infections were consistent with protection of TIV recipients against the seasonal influenza viruses that circulated from January through March 2009 [16]. We identified a statistically significant increased risk of noninfluenza respiratory virus infection among TIV recipients (Table 3), including significant increases in the risk of rhinovirus and coxsackie/echovirus infection, which were most frequently detected in March 2009, immediately after the peak in seasonal influenza activity in February 2009 (Figure 1).

The increased risk of noninfluenza respiratory virus infection among TIV recipients could be an artefactual finding; for example, measurement bias could have resulted if participants were more likely to report their first ARI episode but less likely to report subsequent episodes, whereas there was no real difference in rhinovirus or other noninfluenza respiratory virus infections after the winter influenza season. The increased risk could also indicate a real effect. Receipt of TIV could increase influenza immunity at the expense of reduced immunity to noninfluenza respiratory viruses, by some unknown biological mechanism. Alternatively, our results could be explained by temporary nonspecific immunity after influenza virus infection, through the cell-mediated response or, more likely, the innate immune response to infection [21–23]. Participants who received TIV would have been protected against influenza in February 2009 but then would not have had heightened nonspecific immunity in the following weeks. They would then face a higher risk of certain other virus infections in March 2009, compared with placebo recipients (Figure 1). The duration of any temporary nonspecific immunity remains uncertain [13] but could be of the order of 2–4 weeks based on these observations. It is less likely that the interference observed here could be explained by reduced community exposures during convalescence (ie, behavioral rather than immunologic factors) [14].

The phenomenon of virus interference has been well known in virology for >60 years [24–27]. Ecological studies have reported phenomena potentially explained by viral interference [3–11]. Nonspecific immunity against noninfluenza respiratory viruses was reported in children for 1–2 weeks after receipt of live attenuated influenza vaccine [28]. Interference in respiratory and gastrointestinal infections has been reported after receipt of live oral poliovirus vaccine [29–32].

Our results are limited by the small sample size and the small number of confirmed infections. Despite this limitation, we were able to observe a statistically significant increased risk

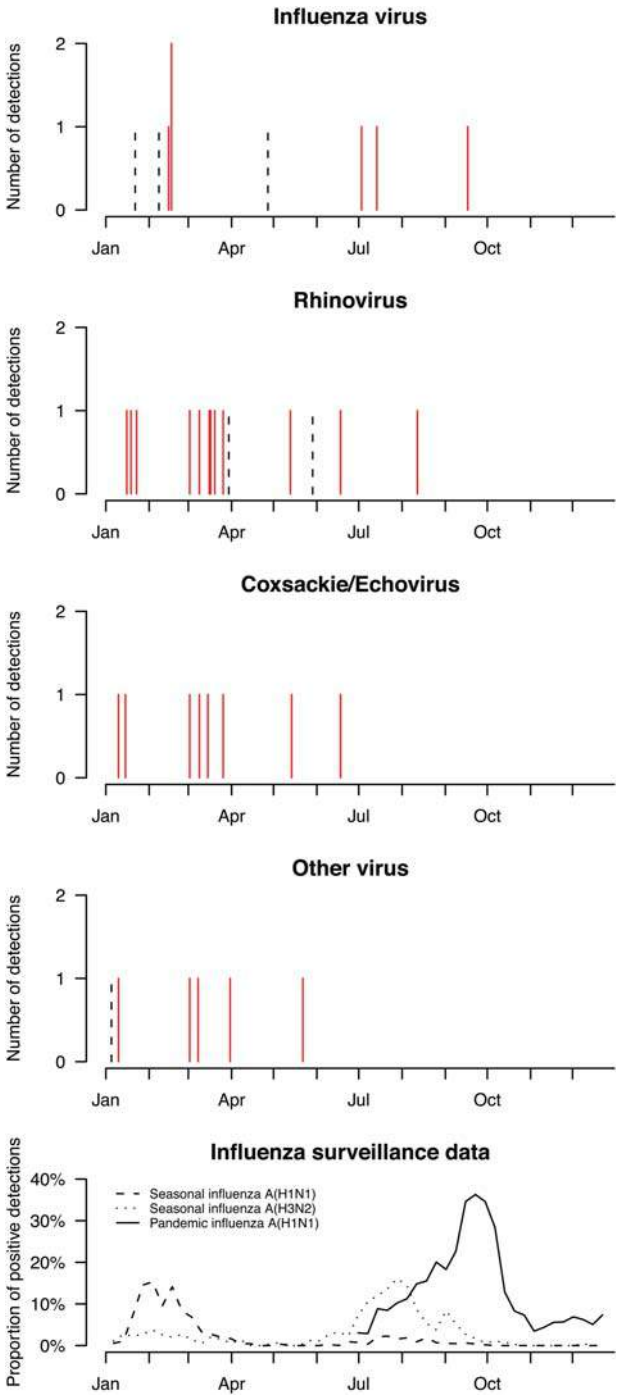

Figure 1. Timing of influenza and other respiratory virus detections in 115 participants aged 6–15 years (*A–D*), compared with local influenza surveillance data (*E*). Solid red bars indicate detections in 69 participants who received 2008–2009 trivalent inactivated influenza vaccine, and black dashed bars indicate detections in 46 participants who received placebo. The bottom panel shows local laboratory surveillance data on the proportion of influenza virus detections among specimens submitted to the Public Health Laboratory Service (PHLS). Less than 2% of PHLS specimens were positive for influenza B throughout the year. "Other viruses" included coronavirus, human metapneumovirus, parainfluenza, and respiratory syncytial virus.

of confirmed noninfluenza respiratory virus infection among TIV recipients (Table 3). A negative association between serologic evidence of influenza infection and confirmed noninfluenza virus infection in winter 2009 was not statistically significant (odds ratio, 0.27; 95% CI, .01–2.05) (Supplementary Appendix). One must be cautious in interpreting serology in children who have received TIV [2, 33]. Finally, acute URTI incidence was based on self-report with regular telephone reminders, and we may have failed to identify some illnesses despite rigorous prospective follow-up.

Temporary nonspecific immunity leading to interference between epidemics of respiratory viruses could have important implications. First, as observed in our trial, TIV appeared to have poor efficacy against acute URTIs (Table 2), apparently because the protection against influenza virus infection conferred by TIV was offset by an increased risk of other respiratory virus infection (Table 3). Second, interference between respiratory viruses could suggest new approaches to mitigating epidemics [32]. Mass administration of live polio vaccine in children has been used to control enterovirus 71 epidemics [10, 31]. Finally, viral interference could bias estimates of influenza vaccine effectiveness in test-negative case-control studies (Supplementary Appendix) [2, 34–43]. One test-negative study reported an association between receipt of TIV and the risk of influenza-like illness associated with a noninfluenza virus [38].

Additional work is required to more fully characterize temporary nonspecific immunity overall and in specific groups, such as children. Animal studies [44–50] and volunteer adult human challenge studies [51] could provide useful evidence. Additional community-based observational cohort studies and community-based experimental studies, such as our vaccine trial, may be particularly suitable for investigating temporary nonspecific immunity, because most acute URTIs do not require medical attention.

Supplementary Data

Supplementary materials are available at *Clinical Infectious Diseases* online (http://www.oxfordjournals.org/our_journals/cid/). Supplementary materials consist of data provided by the author that are published to benefit the reader. The posted materials are not copyedited. The contents of all supplementary data are the sole responsibility of the authors. Questions or messages regarding errors should be addressed to the author.

Notes

Acknowledgments. We thank Chan Kit Man, Calvin Cheng, Lai-Ming Ho, Ho Yuk Ling, Lam Yiu Pong, Tom Lui, Edward Ma, Loretta Mak, Gloria Ng, Joey Sin, Teresa So, Winnie Wai, Lan Wei, Jessica Wong, Eileen Yeung, and Jenny Yuen for research support and Sarah Cobey, Ed Goldstein, Heath Kelly, Nancy Leung, Marc Lipsitch, Ryosuke Omori, Mary Schooling, and Joe Wu for helpful discussions.

Financial support. This work was supported by the Area of Excellence Scheme of the Hong Kong University Grants Committee (grant number AoE/M-12/06), the Hong Kong University Research Council Strategic Research Theme of Public Health, the Harvard Center for Communicable Disease Dynamics from the National Institute of General Medical Sciences (grant number U54 GM088558), and the Research Fund for the Control of Infectious Disease, Food and Health Bureau, Government of the Hong Kong SAR (grant number PHE-2). The funding bodies had no role in study design, data collection and analysis, preparation of the manuscript, or the decision to publish.

Potential conflicts of interest. B. J. C. has received research funding from MedImmune. D. K. M. I. has received research funding from Roche. J. S. M. P. receives research funding from Crucell MV. All other authors report no potential conflicts.

All authors have submitted the ICMJE Form for Disclosure of Potential Conflicts of Interest. Conflicts that the editors consider relevant to the content of the manuscript have been disclosed.

Live Attenuated Influenza Vaccine Enhances Colonization of Streptococcus pneumoniae and Staphylococcus aureus in Mice

Michael J. Mina, Jonathan A. McCullers, Keith P. Klugman

Larry S. McDaniel, Editor

DOI: 10.1128/mBio.01040-13

ABSTRACT

Community interactions at mucosal surfaces between viruses, like influenza virus, and respiratory bacterial pathogens are important contributors toward pathogenesis of bacterial disease. What has not been considered is the natural extension of these interactions to live attenuated immunizations, and in particular, live attenuated influenza vaccines (LAIVs). Using a mouse-adapted LAIV against influenza A (H3N2) virus carrying the same mutations as the human FluMist vaccine, we find that LAIV vaccination reverses normal bacterial clearance from the nasopharynx and significantly increases bacterial carriage densities of the clinically important bacterial pathogens **Streptococcus pneumoniae** (serotypes 19F and 7F) and **Staphylococcus aureus** (strains Newman and Wright) within the upper respiratory tract of mice. Vaccination with LAIV also resulted in 2- to 5-fold increases in mean durations of bacterial carriage. Furthermore, we show that the increases in carriage density and duration were nearly identical in all aspects to changes in bacterial colonizing dynamics following infection with wild-type (WT) influenza virus. Importantly, LAIV, unlike WT influenza viruses, had no effect on severe bacterial disease or mortality within the lower respiratory tract. Our findings are, to the best of our knowledge, the first to demonstrate that vaccination with a live attenuated viral vaccine can directly modulate colonizing dynamics of important and unrelated human bacterial pathogens, and does so in a manner highly analogous to that seen following wild-type virus infection.

IMPORTANCE Following infection with an influenza virus, infected or recently recovered individuals become transiently susceptible to excess bacterial infections, particularly **Streptococcus pneumoniae** and **Staphylococcus aureus**. Indeed, in the absence of preexisting comorbidities, bacterial infections are a leading cause of severe disease during influenza epidemics. While this synergy has been known and is well studied, what has not been explored is the natural extension of these interactions to live attenuated influenza vaccines (LAIVs). Here we show, in mice, that vaccination with LAIV primes the upper respiratory tract for increased bacterial growth and persistence of bacterial carriage, in a manner nearly identical to that seen following wild-type influenza virus infections. Importantly, LAIV, unlike wild-type virus, did not increase severe bacterial disease of the lower respiratory tract. These findings may have consequences for individual bacterial disease processes within the upper respiratory tract, as well as bacterial transmission dynamics within LAIV-vaccinated populations

INTRODUCTION

The conventional view of pathogen dynamics posits that pathogen species act independently of one another. More recently, however, community interactions between pathogens have been recognized as necessary to modulate both health and disease

(1–7). These interactions might be expected to be most prevalent within gut, respiratory, and other mucosal surfaces that harbor complex populations of commensal and, occasionally, pathogenic microbes. In the respiratory tract, for example, viral infections are known to predispose to secondary bacterial invasive disease and pneumonia from pathogens that are most commonly benign but occasionally become virulent, particularly following a viral infection (8–10). A well-known example is the often lethal synergy between influenza virus and pneumococcal or staphylococcal bacterial secondary infections.

Infection with influenza viruses increases susceptibility to severe lower and upper respiratory tract (LRT and URT, respectively) bacterial infections resulting in complications, such as pneumonia, bacteremia, sinusitis, and acute otitis media (11). Bacterial infections may be a primary cause of mortality associated with influenza virus infection in the absence of preexisting comorbidity (12, 13). Primary influenza virus infection increases acquisition, colonization, and transmission of bacterial pathogens (14), most notably the pneumococcus **Streptococcus pneumoniae** and **Staphylococcus aureus** (11, 15).

Although the underlying mechanisms, while well studied, are not entirely defined, they likely include a combination of influenza virus-mediated cytotoxic breakdown of mucosal and epithelial barriers (16–18) and aberrant innate immune responses to bacterial invaders in the immediate postinfluenza state, characterized by uncontrolled pro- and anti-inflammatory cytokine production, excessive leukocyte recruitment, and extensive immunopathology (11, 19–22). When coupled with diminished epithelial and mucosal defenses, such an environment becomes increasingly hospitable for bacterial pathogens to flourish and invade in the days and first few weeks following influenza virus infection.

Increasingly, evidence is linking the early innate immune response triggered by infection or vaccination to sustained adaptive immunity (23). Thus, a broad goal of vaccination is to elicit an immune response analogous to that of the pathogen itself, without subsequent disease (24). The intranasally administered live attenuated influenza vaccine (LAIV) contains temperature-sensitive and attenuated virus designed to replicate efficiently in the cooler temperatures of the upper respiratory tract (URT) but which fails to do so in the warmer temperatures of the lower respiratory tract (LRT) (25, 26). Through selective replication in the URT, LAIV proteins are exposed to the host immune system in their native conformation, eliciting highly robust (IgA), serum (IgG), and cellular immune responses mimicking those of the pathogenic virus itself (27).

Although an innate immune response to vaccination is beneficial for long-term protection from influenza virus (28) and influenza virus-bacterial (29) coinfections, the direct consequences of such a response to a viral vaccine, with respect to secondary colonization and disease due to entirely unrelated bacterial pathogen species, are unknown. As increased susceptibility to and transmission of bacterial pathogens following influenza are due in large part to the innate immune response and breakdowns of the epithelial barriers of the URT, it is important to understand whether similar effects, elicited by live attenuated virus replication, may also predispose to bacterial infection. We sought here to determine the effects of a live attenuated influenza vaccine on URT and LRT bacterial infections. In particular, we ask whether LAIV vaccination alters bacterial colonization dynamics of the upper respiratory tract or disease in the lower respiratory tract of mice.

RESULTS

Using a live attenuated influenza A virus vaccine, HK/Syd 6:1:1 (LAIV), which contains many of the same mutations and demonstrates similar growth dynamics to those in the commercially available human FluMist vaccine (MedImmune, Gaithersburg, MD) (see reference 30 and **Fig. S1** in the supplemental material for vaccine details), we evaluated the effects of LAIV and its wild-type (WT) HK/Syd parent strain (referred to as WT virus) on **Streptococcus pneumoniae** (the pneumococcus) and **Staphylococcus aureus** replication and disease.

Figure S1

H3N2 HK/Syd 1:1:6 live attenuated influenza virus vaccine. LAIV vaccine was developed via site-specific mutagenesis of a parent H3N2 1:1:6 reassortant virus (HK/Syd), as described in reference **30**, containing the surface glycoproteins hemagglutinin (HA) and neuraminidase (NA) from the A/Hong Kong/1/68 (HK68) and A/Sydney/5/97 (Syd97) isolates, respectively, and the six internal protein gene segments from A/Puerto Rico/8/34 or PR8. LAIV consisted of a temperature-sensitive (ts) attenuated variant of HK/Syd (HK/Syd_{ts}) that contains site-specific mutations in the PB1 and PB2 RNA segments of the genome as described in reference **30**. These mutations are found in the attenuated A/Ann Arbor/6/60 master donor strain used to produce the commercial product FluMist (**26**). Download Figure S1, TIFF file, 0.2 MB.

LAIV virus is restricted in growth at 37°C but not at 33°C. To determine whether LAIV virus grows efficiently at temperatures seen within the nasopharynx (NP) while remaining restricted in growth at warmer temperatures of the LRT, WT influenza virus and its LAIV derivative were grown in MDCK cells at 37°C. As expected (**30**), a >3-log decrease in viral titers was measured for LAIV relative to the WT parent strain (**P** < 0.001) (**Fig. 1A**). However, when LAIV was propagated at 33°C, a temperature often associated with the nasopharyngeal environment (**31**), viral replication was no different from that of WT virus titers measured at 37°C.

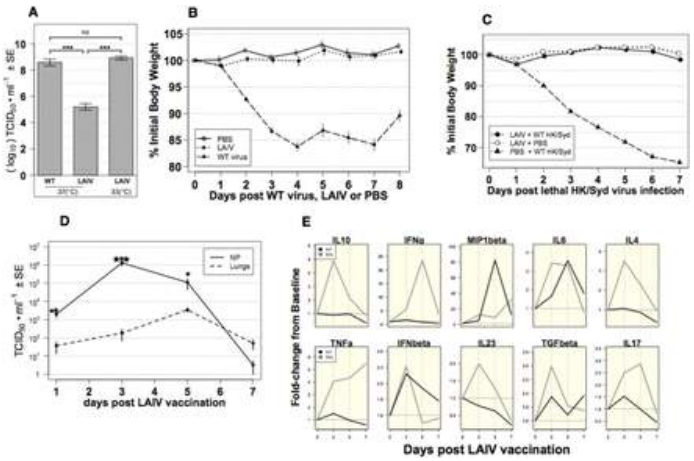

FIG 1

LAIV is safe, effective, replicates well within the URT, and elicits a robust cytokine response. (A) WT and LAIV HK/Syd viruses were grown in MDCK cells at 37°C and LAIV virus was grown at 33°C, and viral titers were measured via the median TCID50 (n = 3 per group). (B) Groups of 12 to 14 8-week-old BALB/c mice were inoculated with 2e6 TCID50 LAIV, WT HK/Syd virus, or PBS and monitored for weight loss. Three of 12 mice and 2/12 mice died at 4 and 7 days postinfection with WT HK/Syd virus, respectively, while no mice died following LAIV or PBS inoculation. (C) Groups of 8 4-week-old BALB/c mice were inoculated with 2e6 TCID50 of LAIV (2 of the 3 groups) or PBS and 4 weeks later infected with a lethal dose (5e7 TCID50) of WT HK/Syd virus or the PBS control. Infection was considered lethal if body weight fell below 70% of the initial body weight. (D) Four groups of 5 mice each were vaccinated with LAIV, and whole lung and NP viral titers were measured at 1, 3, 5, and 7 days postvaccination. (E) Four groups of 5 mice were vaccinated with LAIV, and NP and BAL specimen cytokines were measured at day 0 (unvaccinated mice) and days 3, 5, and 7 following vaccination. Error bars represent standard errors (SE) of the mean. Asterisks indicate statistically significant differences from controls by two-sided Student's t test. *, P < 0.05; **, P < 0.001; ***, P < 0.0001. NS, not significant (no difference between groups).

HK/Syd 1:1:6 LAIV vaccination is safe and effective in mice. Although LAIV is attenuated, inoculation with very high doses may cause morbidity and weight loss. Via a series of dosing experiments (data not shown), a vaccinating dose of 2e6 tissue culture infective doses ($TCID_{50}$) of LAIV in 40 μl phosphate-buffered saline (PBS) vehicle was determined to be safe, with no

weight loss or other detectable signs of morbidity in mice (Fig. 1B). This dose is in agreement with previous studies (28, 30). Inoculation with the same dose of the WT parent virus led to significant morbidity and mortality (5/12 mice succumbed by day 7 postinfection) (Fig. 1B), demonstrating the attenuated nature of the LAIV.

The vaccine efficacy and antibody response using this LAIV strain were described previously (30). To phenotypically confirm efficacy here, groups of 8 4-week-old mice were inoculated with LAIV or the PBS control and 4 weeks later with a lethal dose of the WT virus. Early vaccination with LAIV conferred complete protection from any detectable morbidity or weight loss due to infection with the WT strain, versus 100% mortality in unvaccinated control mice (Fig. 1C).

LAIV is restricted in growth in the lower but not the upper respiratory tract. To determine whether the differences in replication seen **in vitro** also occur **in vivo** in the upper (~33°C) versus lower (~37°C) respiratory tract, groups of 5 mice were vaccinated with LAIV, and viral titers were measured in whole lung and whole NP homogenates (Fig. 1D). By 3 days postvaccination, NP titers were 10,000-fold greater than in the lungs (1.3e6 versus 1.2e2 $TCID_{50}$; **P** < 0.001). In contrast, the WT virus grew to high viral titers in both the NP and lungs (>5e5 $TCID_{50}$) (data not shown), in agreement with previous reports (32), which led to significant morbidity and mortality, as demonstrated in the controls in Fig. 1B. Overall, maximal NP titers occurred earlier and were nearly 400-fold greater than maximum lung titers (1.3e6 versus 3.4e3 $TCID_{50}$; **P** < 0.001). Importantly, these NP viral dynamics are in agreement with viral shedding in NP aspirates from human subjects following vaccination with the FluMist vaccine (33).

LAIV cytokine response in the nasopharynx and lungs. While LAIV replication in the NP induces a robust systemic inflammatory response (34, 35), the cytokine response in the NP has, to our knowledge, not been observed. Nasopharyngeal homogenates and bronchoalveolar lavage (BAL) specimen cytokines were measured in groups of 5 mice each at days 0, 3, 5, and 7 postvaccination (Fig. 1E). Of particular interest, the type I interferon (IFN-β) was significantly increased in the NP and BAL specimens following LAIV vaccination, and this cytokine has been demonstrated to play a pivotal role in excess bacterial colonization of the nasopharynx following WT influenza virus infection (36). As well, macrophage inflammatory protein 1β (MIP-1β) was also significantly upregulated following LAIV, similar to what was seen following influenza virus-pneumococcal coinfections of human middle ear epithelial cells (37). In general, the responses measured here in the NP are similar to those measured from nasopharyngeal washes in humans infected naturally with seasonal influenza A viruses (38).

LAIV enhances pneumococcal bacterial dynamics in the URT in a manner highly analogous to WT influenza virus. Numerous previous investigations have demonstrated that replication of WT influenza virus within the URT predisposes to excess bacterial replication and colonization within the NP, particularly by **Streptococcus pneumoniae** (36, 39, 40). Because, as demonstrated above, LAIV replicates to near WT levels when in the cooler temperatures of the URT, we sought to study effects of LAIV on bacterial carriage density within the NP of mice and compared them to the changes in bacterial carriage following WT virus infection. LAIV vaccination or sublethal infection with the WT parent strain was delivered 7 days following inoculation with a common nasopharynx-colonizing strain of pneumococcus type 19F (Fig. 2A to C) included in the current pneumococcal conjugate vaccine (41). Following vaccination, normal bacterial clearance from the NP was halted, and bacteria reverted to exponential growth within 3 days postvaccination (Fig. 2B). Receipt of LAIV significantly increased the density of bacterial carriage and extended the mean duration of colonization from 35 to 57 days (Fig. 2C). Of particular importance, these effects were nearly identical in all aspects to the effects of the WT influenza virus on bacterial carriage density and duration (Fig. 2B and C). Although no detectable morbidity was associated with vaccination alone (Fig. 1B), vaccination in the presence of bacterial colonization resulted in very mild, though sustained weight loss (~3 to 5%; **P** < 0.05) relative to colonized, unvaccinated controls (see Fig. S2 in the supplemental material) that corresponded with time of greatest excess bacterial proliferation.

Figure S2

Weight changes in colonized mice following LAIV or PBS vehicle. Groups of 12 to 14 BALB/c mice were inoculated with a colonizing dose (1e5 CFU) 19F **Streptococcus pneumoniae** at 7 days prior to receipt of 2e6 $TCID_{50}$ LAIV vaccination or PBS vehicle control, and body weight was monitored. Asterisks indicate statistically significant differences between LAIV-vaccinated mice and PBS controls (**P** < 0.05 by two-sided Student's **t** test). Download Figure S2, TIFF file, 0.3 MB.

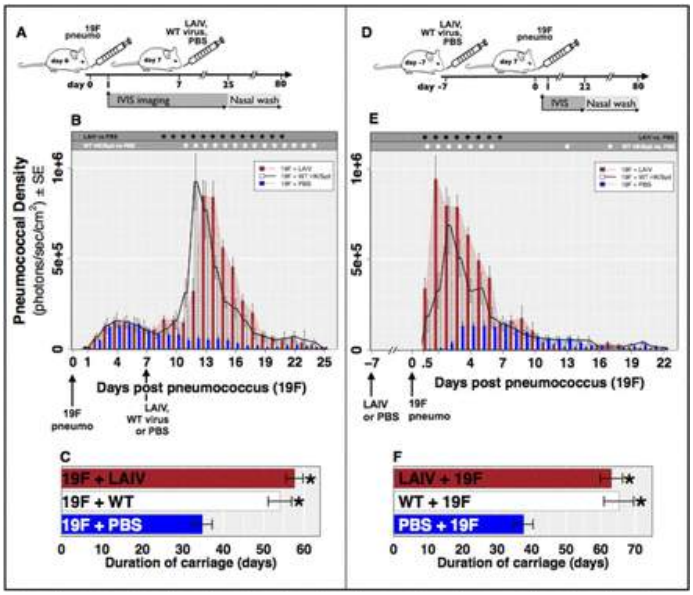

FIG 2

LAIV and WT influenza virus infection similarly enhance 19F pneumococcal carriage density and duration of colonization. Groups of 12 to 14 mice were vaccinated with LAIV and infected with WT influenza virus or PBS vehicle at 7 days following colonization with 19F pneumococcus (A to C) or 7 days prior to colonization with 19F (D to F). Bacterial strains constitutively expressed luciferase, and nasopharyngeal carriage density was measured via in vivo imaging (IVIS) at 12 h postbacterial infection and daily thereafter (B and E). Duration of colonization (C and F) was measured via bacterial plating of nasal washes taken daily after carriage density decreased below the limit of detection for IVIS imaging (~1e4 CFU/ml). Asterisks indicate significant differences between vaccinated (black asterisks in panels B and E) or WT influenza virus-infected (white asterisks in panels B and E) versus control groups (P < 0.05 by Students t test), and error bars represent standard errors around the mean.

To test whether order and timing of vaccination relative to bacterial acquisition are important, LAIV or WT virus was administered 7 days before (rather than after) 19F colonization (**Fig. 2D to F**). Early vaccination or infection with WT virus led to immediate excess bacterial outgrowth following pneumococcal inoculation relative to that in mice pretreated with PBS vehicle (**Fig. 2E**). This increase was generally more pronounced following LAIV vaccination relative to WT virus infection, but the difference only reached statistical significance at day 1 post-bacterial infection. Increases in mean durations of carriage were also demonstrated and were similar between the two groups, with duration extending from 38 days following treatment with PBS to 63 or 65 days following LAIV or WT virus infection, respectively (**Fig. 2F**).

To further define the temporal nature of these interactions and simultaneously test whether this response is strain specific, vaccination was given at either 1 or 7 days prior to infection with a slightly more invasive type 7F pneumococcus (**Fig. 3A**). The maximum bacterial density in both groups of vaccinated mice reached a near 100-fold increase versus that in PBS controls. When inoculation with bacteria followed only 1 day (versus 7 days) postvaccination, similar but delayed dynamics (**Fig. 3A**) and

cumulative bacterial titers (Fig. 3B) were measured. Interestingly, the delay was consistent with the difference in times from vaccination to bacterial inoculation between the two groups.

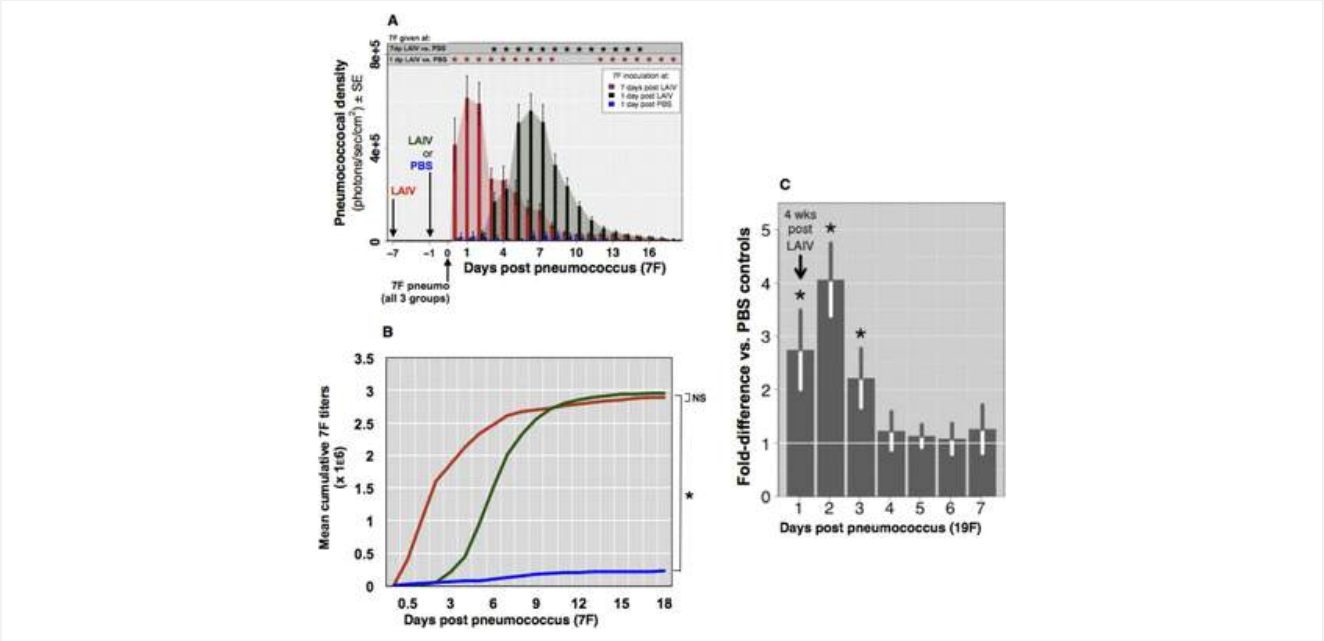

FIG 3

LAIV enhancement of pneumococcal density is time dependent and long lasting. Groups of 12 to 14 mice were vaccinated with LAIV or PBS vehicle at 1 or 7 days prior to colonization with pneumococcal (pneumo) serotype 7F. Bacterial strains constitutively expressed luciferase, and bacterial NP density was measured via IVIS **in vivo** imaging (A and B). Mean cumulative bacterial titers in panel B were calculated by first calculating the cumulative bacterial titers per individual mouse NP at each time point and then calculating the average and SE across the individual cumulative titers per time point, rather than simply averaging the areas under the mean density curves shown in panel A. Asterisks indicate significant differences in bacterial densities between the vaccinated and PBS control groups (dark green indicates LAIV given 7 days prior and red indicates LAIV given 1 day prior to 7F inoculation; **P** < 0.05 by two-tailed Student's **t** test). (C) Groups of mice were vaccinated with LAIV (**n** = 20) or PBS vehicle control (**n** = 30), respectively, at 28 days prior to colonization with 19F pneumococcus. Fold differences per day between mean bacterial densities measured in mice treated 28 days prior with LAIV versus PBS are reported. Error bars indicate standard errors of the mean and asterisks indicate significant differences (**P** < 0.05) from PBS controls (by two-tailed single-sample **t** test).

We sought to understand whether these effects of LAIV vaccination on bacterial proliferation would continue over a longer duration. Mice were infected with pneumococcus 28 days following LAIV vaccination—well after viral clearance from the NP was complete (~7 days postvaccination). Despite the 28-day lag between LAIV and pneumococcal infection, LAIV continued to yield immediate excess bacterial proliferation relative to PBS controls (Fig. 3C); however, the effect was modest and short-lived, with only 2- to 4-fold increases over PBS controls measured between days 1 and 3 postinfection, respectively. By day 4, bacterial density in the NP returned to control levels, and the duration of colonization was not increased.

LAIV enhances Staphylococcus aureus dynamics in the URT. We next sought to test the effects of LAIV on carriage of an entirely distinct but important Gram-positive bacterium, **Staphylococcus aureus**. LAIV was administered 7 days prior to infection with **S. aureus** strain Wright (Fig. 4A and B) or Newman (Fig. 4C and D). Similar to the previous experiments using two strains of pneumococcus, the density of these two strains of **S. aureus** following vaccination was increased at all measured time points for both the Wright and Newman strains (Fig. 4A and C), and duration of colonization was significantly extended 3- to 5-fold over that in the PBS controls (Fig. 4B and D).

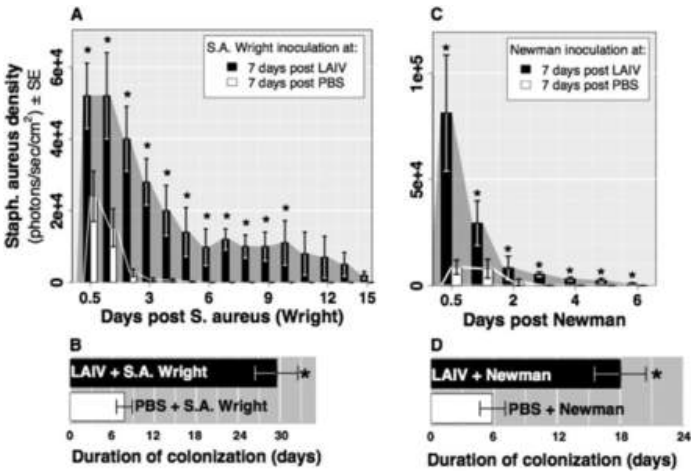

FIG 4

LAIV enhances bacterial load and duration of staphylococcal carriage. Groups of 12 to 14 mice were vaccinated with LAIV or PBS vehicle 7 days prior to colonization with **S. aureus** (S.A.) strain Wright (A and B) or Newman (C and D). **S. aureus** constitutively expressed luciferase, and bacterial density was measured via IVIS **in vivo** imaging. Duration of colonization (B and D) was measured via bacterial plating of nasal washes taken daily after the carriage density decreased below the limit of detection for IVIS imaging. Asterisks indicate significant differences between vaccinated and control groups (**P** < 0.05 by two-sided Student's **t** test), and error bars represent standard errors around the mean.

LAIV does not increase morbidity or mortality from bacterial LRT infections. Given the severe and often lethal interaction seen between circulating influenza virus strains and bacterial lower respiratory tract infections (LRIs) (11, 42), we assessed the effects of LAIV on bacterial LRIs and mortality and compared these effects to those seen following WT influenza virus-bacterial coinfection and single infections with bacteria. Mice received LAIV, WT influenza virus, or PBS control and 7 days later (a time known to maximize the lethal effects of influenza virus-bacterial coinfections [43]) were inoculated with a sublethal dose of either of the highly invasive type 2 or 3 pneumococcal serotypes D39 or A66.1, respectively (Fig. 5A to C).

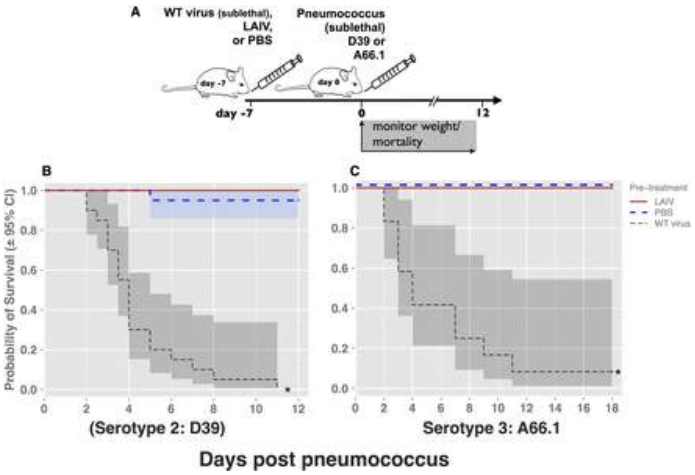

FIG 5

LAIV does not increase severe bacterial disease or mortality. Groups of mice received intranasal LAIV vaccination (solid red curves), sublethal infection with WT influenza virus (broken black curves), or PBS (broken blue curves) 7 days prior to inoculation with a sublethal dose of **Streptococcus pneumoniae** type 2 (1e5 CFU D39; **n** = 20 per group) (B) or type 3 (1e3 CFU A66.1; **n** = 12 to 15 per group) (C), and body weight and mortality were observed at least every 12 h for the first 4 days postpneumococcal inoculation and daily thereafter. Kaplan-Meier survival curves with 95% confidence intervals (CI) were constructed, and asterisks indicate statistically significant differences (**P** < 0.05 by log rank test) between LAIV- or WT virus-infected groups versus PBS controls.

In contrast to the 100% mortality observed when sublethal inoculation with D39 or A66.1 followed pretreatment with wild-type influenza virus, bacterial inoculation following pretreatment with LAIV demonstrated no increases in morbidity (i.e., weight loss; data not shown) or mortality (**Fig. 5B and C**) relative to bacterial infection alone.

DISCUSSION

The potent and often lethal effects of an antecedent influenza virus infection on secondary bacterial disease have been reported previously (**11**, **21**, **44–46**). Viral replication induced epithelial and mucosal degradation, and the ensuing innate immune response yield diminished capacity to avert secondary bacterial infections. Recent clinical and experimental data suggest that influenza virus infection may exert its influence beginning in the URT by enhancing susceptibility to bacterial colonization (**14**, **47**, **48**) and increasing NP carriage density (**36**).

Although vaccination with LAIV, in the longer term, thwarts secondary bacterial infections by inhibiting primary infections with influenza virus (**29**, **49**), the immediate effects of LAIV on bacterial replication and disease have never before been described. Indeed, although vaccines are among our greatest achievements in the constant battle against microbial pathogens, the effects of vaccination on distinct pathogen species unrelated to vaccine-targeted pathogens have, until now, remained entirely unexplored. LAIV viruses selectively replicate in the URT, partially denude the epithelium (**50**), and induce robust innate immune responses that ultimately contribute to long-term protective immunity (**28**). In so doing, LAIV viruses may, like WT influenza viruses, condition the site of replication for enhanced secondary bacterial colonization.

Here, we demonstrated that vaccination with LAIV, like a WT influenza virus, induces swift increases in bacterial density within the URT, with no discernible differences in effects on bacterial dynamics in the NP between the two virus strains. A lag between viral inoculation and excess bacterial replication of at least 3 to 5 days was consistently measured, no matter the bacterial strain. Of particular interest, the type I interferon, IFN-β, known to play a pivotal role in excess pneumococcal colonization following WT influenza virus infections (**36**), was maximally upregulated at 3 days post-LAIV vaccination, coincident with commencement of excess bacterial proliferation. After the 3- to 5-day threshold following vaccination was met, the murine NP remained conditioned for excess pneumococcal replication for at least 28 days (our furthest time point out) post-vaccination. However, as the delay between vaccination and bacterial infection was increased, the magnitude of the effects of vaccination on bacterial dynamics became considerably more modest, although statistically significant excess growth was measured even when acquisition followed 28 days post-vaccination.

While the studies described here are limited in scope to murine models, enhanced bacterial load in the URT following LAIV may agree with human data (**51**), where LAIV has been associated with increases in adverse upper respiratory tract symptoms. Although adverse URT symptoms following administration of FluMist are considered to be of viral etiology, they are most evident in children <5 years of age, where rates of bacterial carriage are greatest (**52**). Potentially corroborating this are data from a large prospective double-blind trial of FluMist (trial no. MI-CP111 [**53**]) that assessed reactogenicity and adverse URT events within the first 28 days following vaccination in ~3,000 children between the ages of 6 and 59 months. This trial demonstrated a bimodal increase in URT symptoms following FluMist vaccination, the first between days 2 and 4 post-vaccination and the second between days 5 and 10 post-vaccination (**53**). While these increased URT events (relative to controls receiving trivalent inactivated influenza vaccine) were considered normal reactions to the live vaccine, the bimodal nature of the increased symptoms suggests that two distinct mechanisms may be in place. In the context of the current findings, the first peak may correspond with viral replication, while the second, more sustained peak may, at least in part, be driven by symptoms due to excess bacterial carriage.

Perhaps the most important finding from our study, with regard to the health of the public and potential concerns regarding vaccination, is that LAIV did not enhance lower respiratory tract infections, morbidity, or mortality following bacterial infections, which are, by most accounts, the most significant issues to be concerned with in terms of respiratory tract bacterial disease.

Indeed, this finding is consistent with numerous epidemiological reports all failing to detect any serious adverse sequelae of LAIV vaccination in humans (51, 54). Furthermore, this finding is consistent with significantly diminished LAIV virus replication within the lower respiratory tract, suggesting that viral replication is a requirement for the synergistic response seen between WT influenza viruses and bacterial LRT infections.

While care should be taken to not overgeneralize the data described here to all vaccines, the broad implications suggest that live attenuated viral vaccines may have unintended consequences on important human bacterial pathogens unrelated to the vaccine target species. Furthermore, our findings suggest a role for laboratory models of multispecies interactions with vaccine strains to inform future vaccine monitoring and evaluation programs aimed at identifying thus far entirely unrealized "unconventional" effects, both beneficial and detrimental, of live attenuated viral vaccines and cross-species microbial dynamics.

MATERIALS AND METHODS

Infectious agents and vaccines. Viral infections were carried out with an H3N2 1:1:6 reassortant virus developed as described previously (30), containing the surface glycoproteins hemagglutinin (HA) and neuraminidase (NA) from A/Hong Kong/1/68 (HK68) and A/Sydney/5/97 (Syd97) isolates, respectively, and the six internal protein gene segments from A/Puerto Rico/8/34 (or PR8; referred to here as WT influenza virus). LAIV vaccinations consisted of a temperature-sensitive (**ts**) attenuated variant of HK/Syd, HK/Syd$_{att/\mathbf{ts}}$ (LAIV) that contains site-specific mutations in the PB1 and PB2 RNA segments of the genome (see Fig. S1 in the supplemental material) as described previously (30). These are the same mutations found in the attenuated A/Ann Arbor/6/60 master donor strain used to produce the influenza A virus strains found in the commercial product FluMist (30). WT and LAIV viruses were propagated in 10-day-old embryonated chicken eggs at 37 and 33°C, respectively) and characterized in Madin-Darby canine kidney cells to determine the 50% infective tissue culture dose (TCID$_{50}$) in wells. The pneumococcal carrier isolates ST425 (serotype 19F) and ST191 (serotype 7F), chosen based on their colonizing potential as previously described (14), were used for colonization experiments. The highly invasive type 2 and type 3 pneumococcal isolates D39 and A66.1, respectively, were used for pneumonia and survival studies. The 19F and 7F strains were engineered to express luciferase, as described previously (14). **Staphylococcus aureus** strains Wright (ATCC 49525) and Newman (ATCC 25905) were engineered to express luciferase by Caliper Life Sciences (Alameda, CA).

Ethics statement. All experimental procedures were approved by the Institutional Animal Care and Use Committee (protocol no. 353) at St. Jude Children's Research Hospital (SJCRH) under relevant institutional and American Veterinary Medical Association guidelines and were performed in a biosafety level 2 facility that is accredited by the American Association for Laboratory Animal Science (AALAS).

Animal and infection models. Eight-week-old BALB/c mice (Jackson Laboratories, Bar Harbor, ME) were used in all experiments, with the exception of mice treated with early vaccination to demonstrate vaccine efficacy and effectiveness. In these cases, 4-week-old BALB/c mice were vaccinated or administered PBS and monitored for 4 weeks before further inoculation. All inoculations and vaccinations were via the intranasal route under general anesthesia with inhaled 2.5% isoflurane (Baxter Healthcare, Deerfield, IL). LAIV vaccination consisted of 2e6 TCID$_{50}$ HK/Syd$_{att/\mathbf{ts}}$ LAIV in 40 µl PBS. The lethal and sublethal doses of WT HK/Syd were 5e7 and 1e5 TCID$_{50}$ in 50 µl PBS, respectively. Pneumococcal infections with 19F and 7F were performed as described previously (14), except inoculation was in 40 µl PBS. Infection with **S. aureus** strains Wright and Newman contained 1e7 CFU in 40 µl PBS. Mortality studies were performed as described previously (43) with sublethal doses of the invasive type 2 and type 3 pneumococcal serotype D39 and A66.1 isolates, consisting of 1e5 and 1e3 CFU in 100 µl PBS (to ensure bacterial entry into the lower lungs), respectively. Animals were monitored for body weight and mortality at least once per day for all survival studies. Mice were sacrificed if body weight fell below 70% initial weight.

Bacterial CFU titers for duration studies. Bacterial CFU titers were measured in nasal washes using 12 µl of PBS administered and retrieved from each nare and quantitated by serial dilution plating on blood agar plates. Washes were

performed daily only after the pneumococcal density fell below the limit of detection for IVIS imaging (~1e4 CFU/ml).

Determination of bacterial and viral titers in lungs and nasopharyngeal homogenates. Viral and bacterial titers were measured in whole lung and nasopharyngeal (NP) homogenates. Whole lungs were harvested and homogenized using a gentleMACS system (Miltenyi Biotech), as per the manufacturer's protocol. NP was isolated via careful dissection dorsally across the frontal bones, laterally via removal of the zygomatic bone, posteriorly by dislocation of the upper jaw from the mandible, and inferiorly just posterior to the soft palate. Isolated NP was homogenized via plunging in 1.5 ml PBS through a 40-μm-mesh strainer. Bacterial titers were measured via plating of serial dilutions, and viral titers were measured by determining the $TCID_{50}$ as previously described (**30**).

Determination of cytokine levels in the NP and BAL specimens by enzyme-linked immunosorbent assay. Nasopharyngeal isolates and BAL specimens were collected as described above, and cytokines were measured using commercially available kits from R&D systems (macrophage inflammatory protein 1β [MIP-1β], transforming growth factor β [TGF-β], and beta interferon [IFN-β]) or eBiosciences (interleukin-4 [IL-4], IL-6, IL-10, IL-17, IL-23, and gamma interferon [IFN-γ]).

Bioluminescent imaging. Mice were imaged using an IVIS charge-coupled device (CCD) camera (Xenogen) as described previously (**14**, **29**). Nasopharyngeal bacterial density was measured as total photons/s/cm^2 in prespecified regions covering the NP, and background (calculated for each mouse on a region of equal area over the hind limb) was subtracted. Each NP measurement represents an average of two pictures, one for each side of the mouse head. Quantitation was performed using LivingImage software (version 3.0; Caliper Life Sciences) as described previously (**14**).

Statistical analyses. All statistical analyses were performed within the R statistical computing environment (version 2.14R; R Foundation for Statistical Computing, R Development Core Team, Vienna, Austria). The specific statistical tests used are as indicated in the legend to each figure. The R package Survival was used for all survival analyses, Kaplan-Meier (KM) plots, and KM log rank tests. All other statistical tests were performed using R base functions.

Abstract

Go to:

Background. Infection with influenza A virus (IAV) increases susceptibility to respiratory bacterial infections, resulting in increased bacterial carriage and complications such acute otitis media, pneumonia, bacteremia, and meningitis. Recently, vaccination with live attenuated influenza virus (LAIV) was reported to enhance subclinical bacterial colonization within the nasopharynx, similar to IAV. Although LAIV does not predispose to bacterial pneumonia, whether it may alter bacterial transmigration toward the middle ear, where it could have clinically relevant implications, has not been investigated.

Methods. BALB/c mice received LAIV or phosphate-buffered saline 1 or 7 days before or during pneumococcal colonization with either of 2 clinical isolates, 19F or 7F. Middle ear bacterial titers were monitored daily via in vivo imaging.

Results. LAIV increased bacterial transmigration to and persistence within the middle ear. When colonization followed LAIV inoculation, a minimum LAIV incubation period of 4 days was required before bacterial transmigration commenced.

Conclusions. While LAIV vaccination is safe and effective at reducing IAV and coinfection with influenza virus and bacteria, LAIV may increase bacterial transmigration to the middle ear and could thus increase the risk of clinically relevant acute otitis media. These data warrant further investigations into interactions between live attenuated viruses and naturally colonizing bacterial pathogens.

Keywords: live attenuated influenza virus, middle ear bacterial colonization, bacterial transmigration, acute otitis media, pneumococcus, coinfection

Infection with influenza A virus (IAV) increases susceptibility to severe lower and upper respiratory tract (URT) bacterial infections, resulting in complications such as pneumonia, bacteremia, sinusitis, and bacterial acute otitis media (AOM) [1]; the latter is a major contributor to the global burden of pediatric disease and remains one of the most common diagnoses leading to the prescription of antimicrobial agents in the United States [2]. While bacterial AOM often occurs in isolation, increasing evidence suggests that primary or concurrent viral respiratory infections of the URT may play uniquely important roles in enhancing bacterial acquisition, colonization, and, ultimately, progression from asymptomatic bacterial carriage to AOM [3], notably from ***Streptococcus pneumoniae*** and ***Staphylococcus aureus*** [1, 4].

Although the mechanisms underlying influenza virus–mediated susceptibility to bacterial AOM are not entirely defined, they likely include a combination of IAV-mediated cytotoxic breakdown of mucosal and epithelial barriers of the URT [5–8] and aberrant innate immune responses to bacterial invaders in the

immediate postinfluenza state, characterized by uncontrolled proinflammatory and antiinflammatory cytokine production, excessive leukocyte recruitment, and immunopathology [1, 9–13]. When coupled with diminished mucosal defenses, such an environment becomes increasingly hospitable for bacterial pathogens to flourish and cause clinical disease in the days and weeks following influenza virus infection.

Increasing evidence links the early innate immune response triggered by vaccination to long-term vaccine efficacy [14]. Thus, a goal of vaccination is to elicit an immune response as close to that elicited by the pathogen itself, without subsequent disease. The intranasally administered live attenuated influenza vaccine (LAIV) is composed of 1:1:6 reassortant viruses containing the hemagglutinin (HA) and neuraminidase (NA) surface proteins from wild-type viruses on a temperature-sensitive and attenuated backbone designed to enable efficient viral replication in the cooler temperatures of the URT but not the warmer temperatures of the lower respiratory tract (LRT) [15, 16]. Through selective replication in the URT, LAIV proteins are exposed to the host immune system in their native conformation, eliciting highly robust immunoglobulin A (IgA), serum immunoglobulin G (IgG), and cellular immune responses mimicking those of the pathogenic virus itself [17], without subsequent virus-mediated disease in the LRT [18, 19].

Recently, we demonstrated that LAIV, while safely providing long-term immunity against influenza and significantly reducing postinfluenza secondary bacterial infections [20], inadvertently enhances the duration and density of bacterial carriage in the nasopharynx of mice [21], a finding that has since been shown in humans [22]. Importantly, in contrast to wild-type IAV infections, LAIV did not alter bacterial outgrowth in the LRT and demonstrated no increases in the incidences of bacterial pneumonia or bacteremia. What is not known is whether LAIV virus replication in the URT may, like that of the wild-type IAV, inadvertently catalyze bacterial migration from the nasopharynx, where it is largely asymptomatic, into the middle ear, where it can increase the risk of symptomatic AOM [13, 23, 24]. Such an effect of the attenuated virus could result from LAIV-mediated inflammation of the epithelial cells of the pharyngotympanic tube [13] or from elevated bacterial density within the nasopharynx [25].

MATERIALS AND METHODS

Go to:

Vaccinations and Infectious Agents

LAIV viruses were developed from a parent H3N2 1:1:6 reassortant virus developed as described previously [26]. The surface glycoproteins HA and NA were from the A/Hong Kong/1/68 (HK68) and A/Sydney/5/97 (Syd97) isolates, respectively, and the 6 internal protein gene segments were from A/Puerto Rico/8/34 or PR8 (referred to hereafter as WT virus). LAIV consisted of a temperature-sensitive (***ts***) attenuated variant of the WT virus (HK/Syd_{ts}) that contains site-specific mutations in the PB1 and PB2 RNA segments of the genome as described previously [26, 27]. These mutations are found in the attenuated A/Ann Arbor/6/60 master donor strain used to produce the commercial product known as FluMist (MedImmune, Gaithersburg, Maryland) [16]. LAIV viruses were propagated in 10-day-old embryonated chicken eggs at 33°C and quantitated in Madin–Darby canine kidney cells using the median tissue culture infective dose ($TCID_{50}$). In vitro and in vivo growth dynamics have been reported elsewhere [21]. The pneumococcal carrier isolates ST425 (serotype 19F) and ST191 (serotype 7F) have been previously described [3]. These strains were engineered to express luciferase, as described elsewhere [3, 28].

Animal and Infection Models

Eight-week-old BALB/c mice (Jackson Laboratories, Bar Harbor, Maine) were used in all experiments. All inoculations were via the intranasal route. LAIV consisted of 2×10^6 $TCID_{50}$ HK/Syd_{ts} virus in 40 µL of phosphate-buffered saline (PBS). Pneumococcal infections with 19F and 7F ***Streptococcus pneumoniae*** were as described previously [3]. Briefly, bacterial cultures were grown in Todd–Hewitt broth (Difco Laboratories, Detroit, Michigan) containing 0.5% yeast (THY) until mid- to late-log phase (OD, approximately 0.3,) and aliquots were stored at −80°C in 10% glycerol and quantified via serial dilution on blood agar plates. Inoculations were prepared from frozen aliquots and consisted of 1×10^6

and 1×10^5 colony-forming units of serotype 19F and 7F pneumococci, respectively, in 25 µL of PBS. Infections were initialized via careful administration of 12.5 µL of bacteria to each naris under general anesthesia with 2.5% inhaled isoflurane (Baxter Healthcare, Deerfield, Illinois). All experiments were conducted in biosafety level 2 facilities in a manner in accordance with the guidelines of the Committee on the Care and Use of Laboratory Animals.

Bioluminescent Imaging

Mice were imaged using an IVIS CCD camera (Xenogen) as described elsewhere [3]. Middle ear bacterial density was measured as total photons sec^{-1} cm^{-2} in prespecified regions covering the middle ear canal, and background (calculated for each mouse on a region of equal area over the hind limb) was subtracted. Positivity for bacteria within the middle ear was defined as a value of >40 000 photons sec^{-1} cm^{-2}. This threshold has been previously described for this infection model, using the same instruments and laboratory environment [29]. Quantitation was performed using Living Image software (v. 3.0; Caliper Life Sciences) as described previously [3].

Although bioluminescent imaging of ***lux***-expressing bacteria has previously been shown to be an efficient and accurate method for measuring bacterial density in the nasopharynx and lungs of mice and ferrets in vivo [3, 21, 29, 30], to ensure imaging was also appropriate for measuring bacterial presence and density within the middle ear, we compared values obtained from imaging to bacterial titers obtained by traditional methods. In short, the middle ear was dissected and completely homogenized in 1 mL of PBS, and serial dilutions were plated on 5% blood agar plates for quantification. Bacterial counts obtained from serial dilution plating were plotted against values obtained via IVIS just before dissection and showed strong linear correlation ($R^2 = 0.92$; Supplementary Figure 1).

A single episode of bacterial middle ear colonization (MEC) was defined as any continuous detection of bacteria that was not interrupted by an interval of >2 days. This 2-day interval was important to account for normal fluctuations in bacterial density, whereby densities can temporarily fall below the threshold of detection (described above) without actually being cleared and then return to high levels. Additionally, episodes were categorized as early or late onset. Early onset was defined as an initial episode of MEC in a given mouse that occurred within 5 days of bacterial inoculation. Late onset was defined as any episode that commenced at least 2.5 days after clearance of a previous episode or at least 5 days after pneumococcal infection.

Statistical Analyses

All statistical analyses were performed within the R statistical computing environment (R, version 2.14; R Foundation for Statistical Computing, R Development Core Team, Vienna, Austria). Kaplan–Meier curves were constructed for freedom from MEC for each mouse per group, and the log-rank test was used to calculate statistically significant differences between groups. The frequency of MEC was plotted using Loess smoothing (span 0.2), and differences between daily frequencies in the vaccinated groups and those in the PBS controls were calculated using the Fisher exact test for differences in proportions. Differences in mean duration of MEC were calculated using 2-tailed 2-sample Students ***t*** tests. The false detection rate was used to adjust for multiple comparisons where appropriate, and statistical significance was considered when the calculated probability had an α level of <0.05.

RESULTS

Go to:

LAIV Increases the Incidence of MEC in Mice Colonized With Pneumococci Before LAIV Receipt

Nasopharyngeal carriage of pneumococcus is believed to be a prerequisite for MEC and subsequent pneumococcal AOM, and elevated bacterial density has been associated with transition from asymptomatic carriage to middle ear infections [25]. To determine whether LAIV vaccination of pneumococci-colonized mice may enhance bacterial transmigration to the middle ear, groups of 12–14 mice were colonized with serotype 19F pneumococcus (a clinical isolate often found colonizing the

nasopharynx of children and a well-established model organism for colonization and AOM in mice [3]) 7 days before LAIV or PBS inoculation. A delay of 7 days was used because this was shown to be a sufficient interval over which bacteria reached stable colonization, as assessed via IVIS imaging of the nasopharynx and as previously reported [31]. Within 12 hours after LAIV inoculation, mice demonstrated an increased incidence of MEC (Figure 1), as determined by in vivo imaging of the middle ear (see "Materials and Methods" section). By day 4 after LAIV receipt, 85% of mice had at least 1 episode of MEC, compared with only 25% of PBS controls. In the majority of cases, initial onset of MEC in the LAIV group occurred within the first 4 days following vaccination, and freedom from MEC stabilized in both groups after day 5 (with the exception of a single new case in the PBS group, which was detected on day 9). By day 10 following LAIV or PBS inoculation, the incidence of MEC in LAIV recipients remained significantly greater than that in PBS controls (85% in LAIV recipients vs 50% in PBS controls; ***P*** = .017).

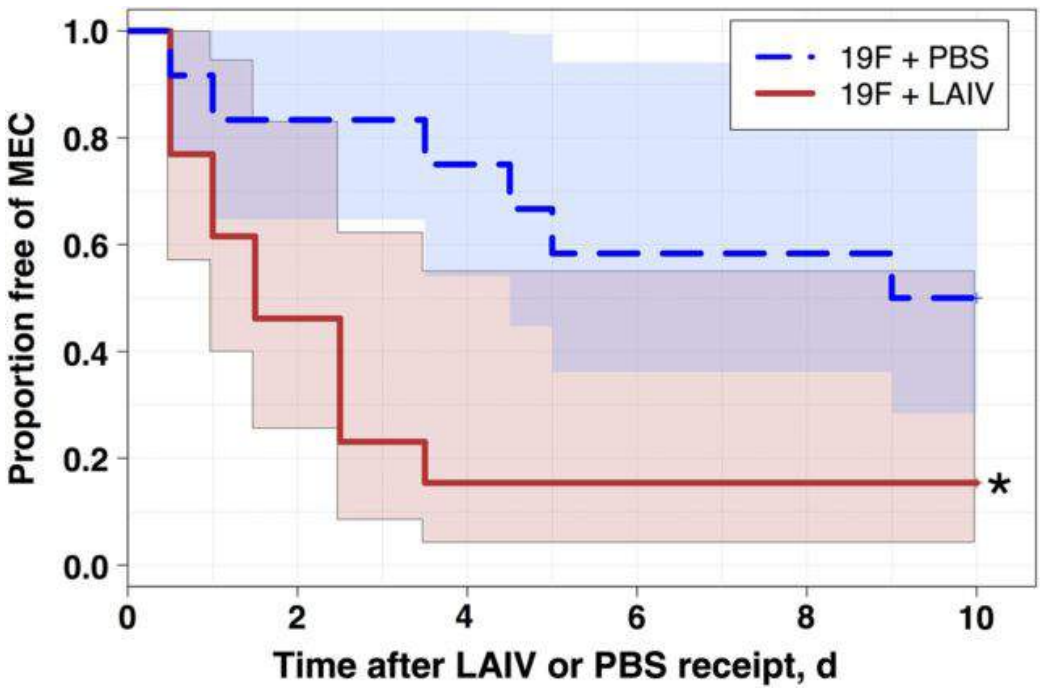

Figure 1.

Live attenuated influenza virus (LAIV) enhances the incidence of bacterial middle ear colonization (MEC) in precolonized mice. Groups of 12–14 8-week-old BALB/c mice were colonized intranasally with serotype 19F pneumococcal bacteria engineered to express luciferase. Seven days later, mice were inoculated with LAIV or phosphate-buffered saline (PBS) vehicle as a control. MEC was measured via in vivo imaging of the middle ear at 12-hour intervals for the first 2 days following LAIV or PBS receipt and daily thereafter. Initial onset of bacterial MEC was recorded for each mouse, and Kaplan–Meier survival curves were constructed. Data are reported as freedom from MEC after LAIV or PBS inoculation, and the log-rank test was used to determine statistically significant differences between groups. *$P < .05$, compared with PBS controls.

Antecedent Receipt of LAIV Predisposes to Bacterial Transmigration

To address whether antecedent inoculation with LAIV predisposes to MEC after bacterial infection, and to ensure that the effect of LAIV on bacterial transmigration is not specific to serotype 19F pneumococci, mice received a colonizing dose of pneumococcal serotype 7F (a slightly more invasive clinical strain and a well-described model organism for pneumococcal AOM in mice [3]) at either 7 days

or 1 day after LAIV receipt (n = 26 for each group) or 1 day after PBS receipt (n = 20; Figure 2). Inoculation with LAIV 7 days before pneumococcal infection led to immediate increases in the incidence of MEC, with only 30% (8 mice) remaining free from bacterial MEC 24 hours after infection; compared with 81% (21 mice) infected 1 day after LAIV receipt and 75% (15 mice) infected 1 day after PBS receipt. Following initial enhancement of MEC in mice infected 7 days after LAIV receipt, only 2 new cases (ie, cases in mice previously free from MEC) were seen over the following 2 weeks, at days 5 and 8 after bacterial infection.

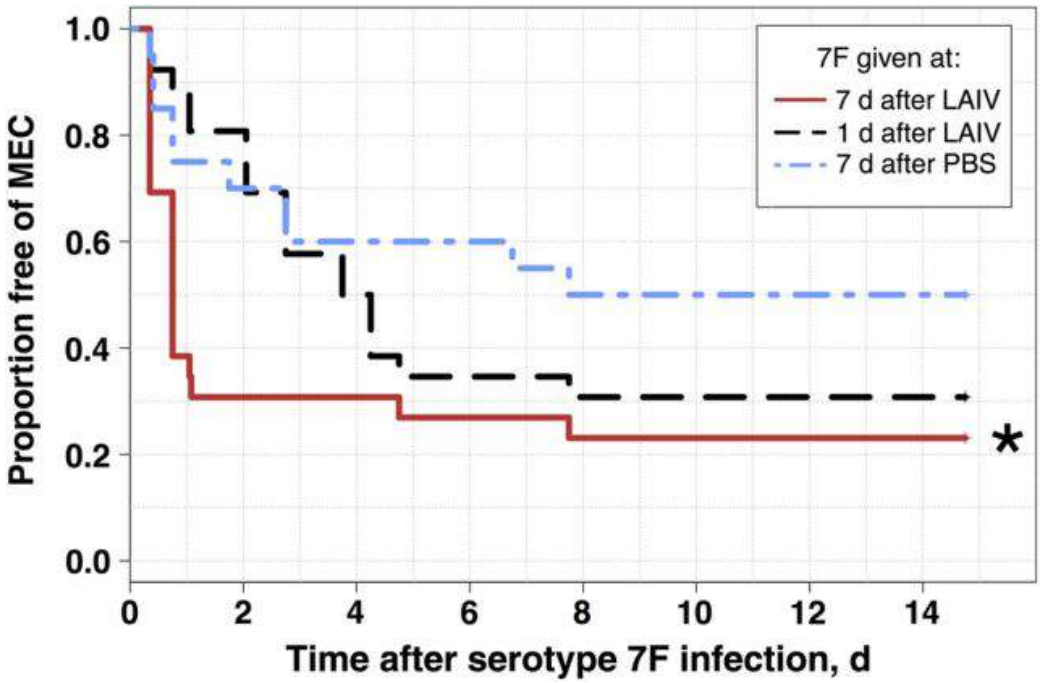

Figure 2.

Freedom from middle ear colonization (MEC) following bacterial infection in recently vaccinated mice. Groups of 8-week-old BALB/c mice received live attenuated influenza virus (LAIV) 7 days (n = 26), LAIV 1 day (n = 26), or phosphate-buffered saline (PBS) 1 day (n = 20) before inoculation with serotype 7F pneumococcal bacteria engineered to express luciferase. In vivo imaging was used to detect bacterial MEC every 12–15 hours for the first 2 days following pneumococcal infection and at least daily thereafter. Initial onset of pneumococcal MEC was recorded for each mouse, and Kaplan–Meier survival curves were constructed to describe freedom from pneumococcal MEC. ***P*** < .05, by the log-rank test, compared with PBS controls, corrected for multiple comparisons using the false-discovery rate.

An increased incidence of MEC was also detected in the group infected 1 day after LAIV receipt, but onset was distributed in this group, commencing between days 3 and 5 after infection, which corresponded to days 4–6 after LAIV receipt, a time previously demonstrated to maximize bacterial colonization of the nasopharynx [21].

LAIV-Mediated Enhancement of Bacterial Transmigration Is Delayed After Vaccination

To better understand the dynamics of bacterial transmigration and MEC, we investigated the overall frequency per day of MEC for each group (Figure 3), which differs from our Kaplan–Meier analysis above in that the Kaplan–Meier analysis considers only time of first onset in a given mouse, rather than overall proportion with MEC at any particular time in our experimental groups. Consistent with the Kaplan–Meier analysis, mice vaccinated 7 days before pneumococcal infection had significantly

increased frequencies of MEC for the first 24–48 hours after infection, compared with PBS controls. The frequency peaked in this group approximately 24 hours after infection, with slightly >60% (16 mice) with MEC. In contrast, only 20–30% of mice receiving LAIV or PBS 1 day before bacterial infection had evidence of MEC, and these episodes were very short lived, with almost no MEC in these groups by day 2. While the maximum frequency of MEC was reached 24 hours after infection in the group infected 7 days after LAIV receipt, mice infected only 1 day following LAIV receipt had a second wave of MEC episodes that began 4 days after LAIV receipt (Figure 3). This second wave of MEC, while lower in maximum frequency (approximately 40%) than in the group infected 7 days after LAIV receipt, had a broader and more sustained peak that lasted from day 4 to day 8 after bacterial infection.

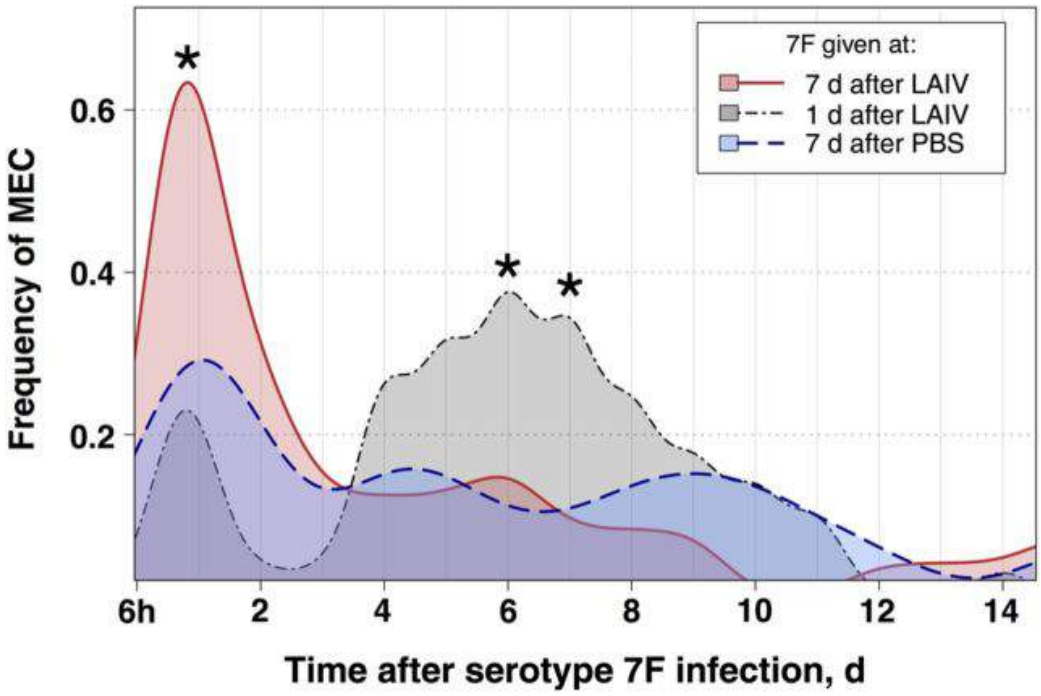

Figure 3.

Frequency of middle ear colonization (MEC) following bacterial infection in recently vaccinated mice. Mice were inoculated with live attenuated influenza virus (LAIV) 7 days (n = 26), LAIV 1 day (n = 26), or phosphate-buffered saline (PBS) 1 day (n = 20) before infection with serotype 7F pneumococcus engineered to express luciferase, and in vivo imaging of the middle ear was performed to measure the presence of pneumococcal MEC. The frequency of MEC is plotted for each group, and differences in the daily frequency between groups were tested for statistical significance using the Fisher exact test for differences in proportions. ***P*** < .05, compared with the PBS group.

LAIV Increases the Persistence of MEC

The duration of MEC was measured for each episode per mouse, as defined above, and mean durations were calculated for each group. The duration was significantly increased across all vaccinated groups, regardless of pneumococcal strain (ie, serotype 19F or 7F) or whether LAIV was given before or following pneumococcal infection. When LAIV or PBS was administered to mice with preestablished serotype 19F colonization, bacteria persisted in the middle ears nearly 2-fold longer than in PBS controls (2.3 vs 1.2 days; ***P*** < .05; Figure 4***A***). Similarly, when mice received LAIV 7 days or 1 day before bacterial infection, the mean durations of MEC episodes were 3-fold and 2-fold greater, respectively, than those for PBS controls (***P*** < .05 for each comparison; Figure 4***B***). Interestingly, when episodes were classified into early and late onset (see “Materials and Methods” section for classification criteria),

durations of early onset cases in the group infected 7 days after LAIV receipt were almost identical to durations of late-onset cases in the group infected 1 day after LAIV receipt (approximately 3.75 days in each group) and, in each case, the duration was >2-fold greater than that for their respective PBS controls (approximately 1.5 days; ***P*** < .05; Figure 4***C***). Alternatively, the duration of early onset episodes in the group infected 1 day after LAIV receipt and the duration of late-onset episodes in the group infected 7 days after LAIV receipt were no different than for PBS controls. Taken together with the findings of Kaplan–Meier analyses described above, these data demonstrate a strong influence of time since LAIV inoculation, rather than time since bacterial infection, with a minimum of 4 days after vaccination required before enhanced bacterial transmigration to and colonization of the middle ear is detected.

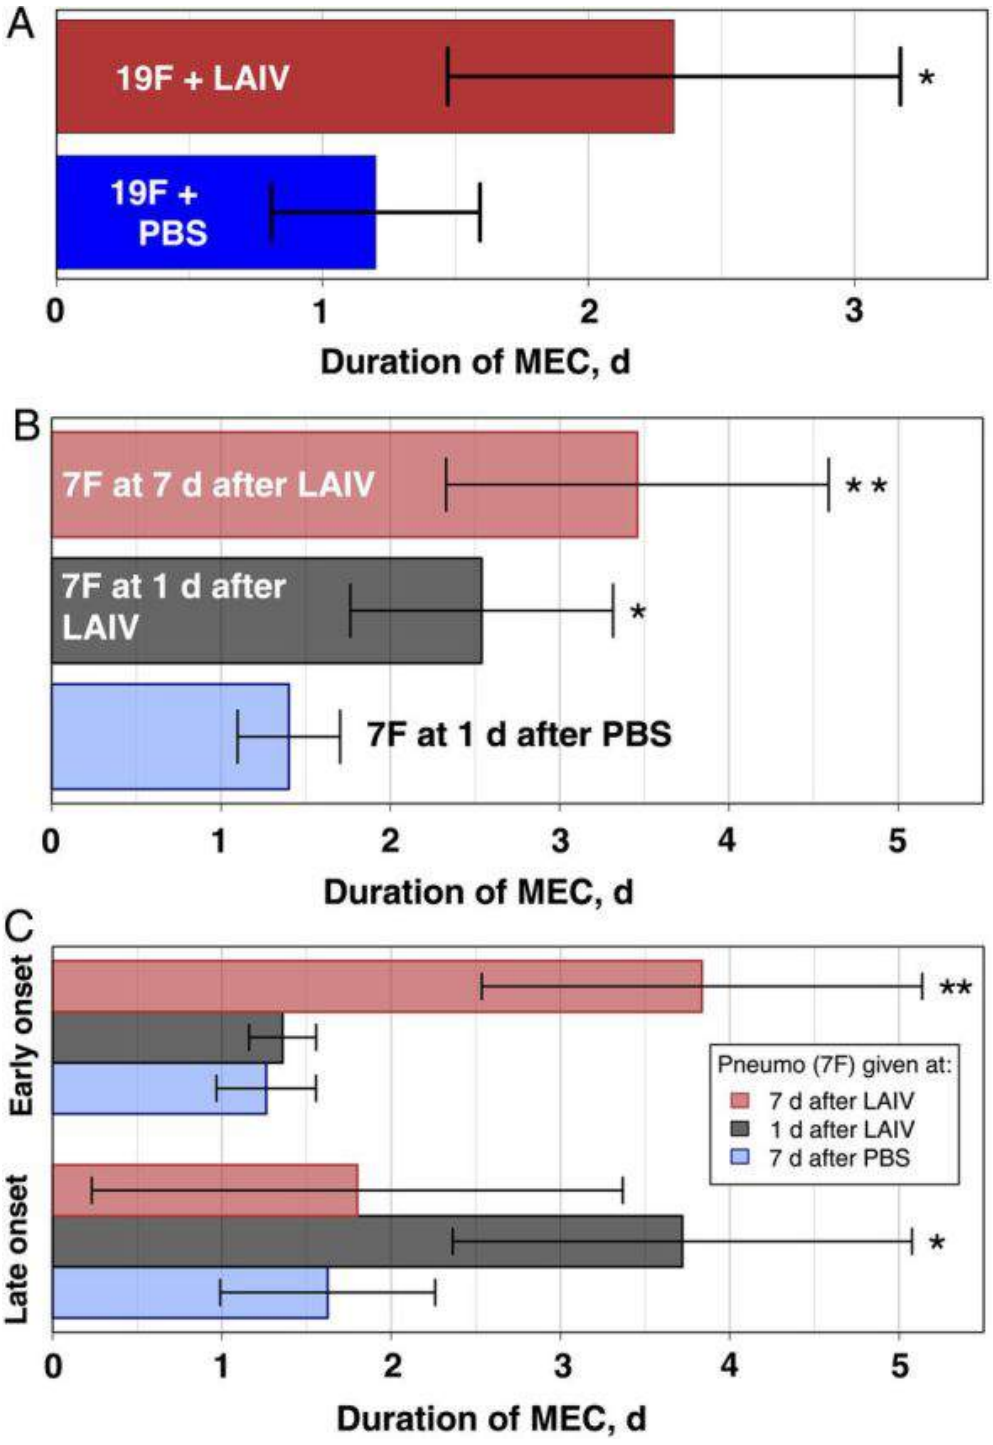

Figure 4.

Live attenuated influenza virus (LAIV) enhances persistence of middle ear colonization (MEC). ***A*** and ***B***, Groups of mice were colonized with serotype 19F pneumococcus 7 days before inoculation with LAIV (n = 14) or phosphate-buffered saline (PBS; n = 12; ***A***) or received LAIV 7 days (n = 26), LAIV 1 day (n = 26), or PBS 1 day (n = 20) before infection with serotype 7F pneumococcus (***B***). The durations of MEC episodes were measured, and mean durations reported for serotype 19F (***A***) and serotype 7F (***B***) MEC, in which a single episode was defined as any continuous detection in a given mouse that was not interrupted by >2 days. ***C***, Episodes of serotype 7F MEC were further classified as early onset (onset within the first 5 days following infection) or late onset (>2 days following termination of an early episode or >5 days after infection), and mean durations reported for each group. Statistically significant differences (vs PBS controls) were tested using 2-tailed 2-sample Student ***t*** tests with correction for multiple comparisons, using the false-discovery rate. Error bars represent 95% confidence intervals around the mean. ****P*** < .05, *****P*** < .001.

DISCUSSION

Go to:

The potent and often lethal effects of a previous influenza virus infection on secondary pneumococcal invasive disease and pneumonia have been reported [1, 11, 32–34]. Viral replication induced epithelial and mucosal degradation, and the ensuing innate immune response yield diminished capacity to avert secondary bacterial infections. Recent clinical and experimental data suggest that influenza viruses may exert their influence, beginning in the URT, by enhancing susceptibility to bacterial colonization [3, 30, 35], increasing nasopharyngeal carriage density [23], and enhancing the incidence of AOM [13].

Although LAIV, in the longer-term, thwarts influenza virus and bacterial coinfections by inhibiting the viral infection [18, 31], LAIV vaccines have recently been found to enhance the density and duration of bacterial colonization within the nasopharynx of mice, and evidence has also been put forth for humans [21, 22, 36]. Importantly, unlike WT IAV, LAIV did not result in increased bacterial proliferation or disease in the LRT, presumably because of the temperature-sensitive nature of LAIV viruses, abrogating viral growth within the warmer temperatures of the lungs. Although LAIV did not effect clinical bacterial LRT infections, the effects of LAIV on transition from colonization to bacterial disease within the URT, a region where LAIV replicates efficiently, had not been studied.

Here, we found that vaccination with a mouse-adapted LAIV significantly increased bacterial transmigration to the middle ear and the duration of MEC, irrespective of bacterial serotype or order of viral versus bacterial inoculation. Interestingly, a minimum period of approximately 4 days was required before enhancement in pneumococcal transmigration and MEC was noted, when LAIV preceded pneumococcal infection.

The dynamics of increased MEC, with regard to time since vaccination, closely match increased pneumococcal colonizing dynamics of the nasopharynx following WT IAV or LAIV virus [21, 31] and support the notion that nasopharyngeal colonizing density may be associated with progression to AOM. Interestingly, the delay in increased onset of migration and MEC in mice vaccinated only 1 day before bacterial inoculation was approximately the same as the time to peak LAIV viral titers in the URT [21]. Thus, a majority of excess MEC occurs during or soon after viral clearance from the URT. This finding supports numerous reports [1, 10–12, 23] that point toward a complex coupling of poorly coordinated antibacterial innate immune defenses and epithelial damage following influenza virus infection, underlying the excess susceptibility to bacterial disease after influenza virus infection.

On the other hand, the steady increase in onset of MEC measured immediately following LAIV vaccination in serotype 19F–precolonized mice suggests that introduction of LAIV virus in the presence of existing bacterial colonization yields enhanced MEC that is concurrent with viral replication and precedes viral-mediated enhanced nasopharyngeal colonization, which tend to increase beginning on day 4 after LAIV inoculation. This suggests that the mechanisms of virus-induced bacterial AOM may differ according to order of inoculation. Indeed, it may be that even low levels of viral replication in the URT, while not immediately affecting overall bacterial carriage density in the nasopharynx, may rapidly

disrupt a delicate balance that naturally exists to prevent asymptomatic carriage from transitioning to bacterial AOM.

It must be clearly emphasized here that any animal study, particularly mouse studies [37], must be viewed in light of the many caveats that exist when extrapolating findings from animal studies to humans. Although animal studies have been integral to our understanding of infectious diseases (and many other biological systems), the individual processes and dynamics often differ between the animal model—mice, in this case—and the human system, as has been shown [37].

While our data suggest that LAIV may enhance pneumococcal transmigration into the middle ear, it is clear that the overall effect of LAIV measured in humans has been that of significant reductions in viral influenza infections and otitis media [38]. While our data suggest a potential effect of LAIV to increase bacterial transmigration to the middle ear, a lack of detection in numerous large clinical trials in humans suggests that any effect is largely subclinical. As well, LAIV-mediated protection from primary influenza virus infections significantly reduces the opportunity for worse secondary bacterial infections [20], further reducing the incidence of LRT and URT bacterial disease, including bacterial AOM.

While we are confident that the overall effects of LAIVs are beneficial to reduce all-cause AOM across populations, as has been reported [39], our data here and previous reports [21] suggest a need for future investigations to more closely evaluate the effects of LAIV on bacterial respiratory pathogen dynamics, including unintended beneficial effects [20]. Indeed, as medicine becomes increasingly personalized [40], it may become possible to tailor classes of vaccines and avenues of vaccine delivery to the individual. In this particular example, considering the benefits of LAIV over inactivated injectable influenza vaccines [41], one could envision that the choice between a killed injectable vaccine and an intranasal LAIV might incorporate the risk of pneumococcal carriage or acquisition (based on factors such as the number of children in the household, the age of the vaccine recipient, and proximity to immunocompromised individuals) as a potential variable in the decision-making process.

Effect of pneumococcal conjugate vaccine on nasopharyngeal bacterial colonization during acute otitis media.

Revai K[1], McCormick DP, Patel J, Grady JJ, Saeed K, Chonmaitree T.

Author information

Abstract

The heptavalent pneumococcal conjugate vaccine (PCV7) has been shown to reduce the incidence of acute otitis media (AOM) caused by Streptococcus pneumoniae by 34% and reduces the overall incidence of AOM by 6% to 8%. More recent studies have shown increases in the proportion of Haemophilus influenzae and Moraxella catarrhalis in the middle-ear fluid of PCV7-immunized children. There has been no report on the effect of PCV7 on all 3 bacterial pathogens combined, either in the middle-ear fluid or nasopharynx of individual children with AOM. We investigated the impact of PCV7 on nasopharyngeal colonization with bacterial pathogens during AOM in the pre-PCV7 and post-PCV7 vaccination eras. Four hundred seventeen children (6 months to 4 years of age) were enrolled onto AOM studies between September 1995 and December 2004. Of these, 200 were enrolled before the vaccine use (historical controls), and 217 were enrolled after the initiation of PCV7 vaccination (101 were underimmunized, and 116 were immunized). Although the nasopharyngeal colonization rate for S pneumoniae was not different between the 3 groups, a significantly higher proportion of PCV7-immunized children with AOM were colonized with M catarrhalis. Overall, the mean number of pathogenic bacteria types isolated from immunized children (1.7) was significantly higher than in controls (1.4). The increase in bacterial colonization of the nasopharynx during AOM could be associated with an increase in AOM pathogens and theoretically can predispose PCV7-immunized children with AOM to a higher rate of antibiotic treatment failure or recurrent AOM.

Children Who Get Flu Vaccine Have Three Times Risk Of Hospitalization For Flu, Study Suggests

Date: May 20, 2009

Source: American Thoracic Society

Summary: The inactivated flu vaccine does not appear to be effective in preventing influenza-related hospitalizations in children, especially the ones with asthma. In fact, children who get the flu vaccine are more at risk for hospitalization than their peers who do not get the vaccine, according to new research. While these findings do raise questions about the efficacy of the vaccine, they do not in fact implicate it as a cause of hospitalizations, according to researchers.

FULL STORY

The inactivated flu vaccine does not appear to be effective in preventing influenza-related hospitalizations in children, especially the ones with asthma. In fact, children who get the flu vaccine are more at risk for hospitalization than their peers who do not get the vaccine, according to new research that will be presented on May 19, at the 105th International Conference of the American Thoracic Society in San Diego.

Flu vaccine (trivalent inactivated flu vaccine—TIV) has unknown effects on asthmatics.

"The concerns that vaccination maybe associated with asthma exacerbations have been disproved with multiple studies in the past, but the vaccine's effectiveness has not been well-established," said Avni Joshi, M.D., of the Mayo Clinic in Rochester, MN. "This study was aimed at evaluating the effectiveness of the TIV in children overall, as well as the children with asthma, to prevent influenza-related hospitalization."

The CDC's Advisory Committee on Immunization Practices (ACIP) and the American Academy of Pediatrics (AAP) recommend annual influenza vaccination for all children aged six months to 18 years. The National Asthma Education and Prevention Program (3rd revision) also recommends annual flu vaccination of asthmatic children older than six months.

In order to determine whether the vaccine was effective in reducing the number of hospitalizations that all children, and especially the ones with asthma, faced over eight consecutive flu seasons, the researchers conducted a cohort study of 263 children who were evaluated at the Mayo Clinic in Minnesota from six months to 18 years of age, each of whom had had laboratory-confirmed influenza between 1996 to 2006. The investigators determined who had and had not received the flu vaccine, their asthma status and who did and did not require hospitalization. Records were reviewed for each subject with influenza-related illness for flu vaccination preceding the illness and hospitalization during that illness.

They found that children who had received the flu vaccine had three times the risk of hospitalization, as compared to children who had not received the vaccine. In asthmatic children, there was a significantly higher risk of hospitalization in subjects who received the TIV, as compared to those who did not ($p = 0.006$). But no other measured factors—such as insurance plans or severity of asthma—appeared to affect risk of hospitalization.

"While these findings do raise questions about the efficacy of the vaccine, they do not in fact implicate it as a cause of hospitalizations," said Dr. Joshi. "More studies are needed to assess not only the immunogenicity, but also the efficacy of different influenza vaccines in asthmatic subjects."

We present two cases of bacterial meningitis caused by *Haemophilus influenzae* type b (Hib) which developed a few days after conjugate Hib vaccination. This phenomenon of postimmunization provocative time period is reviewed and discussed. These cases serve as a reminder to clinicians of the risk, albeit rare, of invasive Hib disease in the short period after successful immunization.

1. Introduction

Haemophilus influenzae type b (Hib) was the leading cause of bacterial meningitis in children worldwide until the introduction of the Hib conjugate vaccine in the early 1990s [1]. Since then, the incidence of Hib disease has declined dramatically in high-income countries and virtually eliminated in parts of the United States and Europe [1].

In 1994, the Hib-conjugated vaccine was introduced into the Israeli National Immunization Program. In 1997, a four-dose vaccine schedule was adopted, given at 2, 4, 6, and 12 months of age. Prospective surveillance estimated that vaccine effectiveness was 95% (95% CI 92–96%) against any invasive disease and 97% (95% CI 93–98%) against bacterial meningitis [2].

Nevertheless, over the past 20 years, there have been some reports of invasive Hib disease within a short period after administration of the vaccine [3–5]. This report describes two children in whom Hib meningitis developed a few days after vaccination. These cases serve as a reminder for clinicians of a phenomenon of elevated risk for infection and apparent vaccine failure in the short period after Hib immunization.

2. Case Reports

2.1. Case 1. A 10-week-old girl presented to another hospital with fever, refusal to eat, grunting respirations, and hypertonicity of 48-hour duration. All symptoms began one day after she had received the first dose of the combination Infanrix-IPV+Hib vaccine (a combined vaccine against diphtheria, tetanus, pertussis, polio, and Hib infections). Her parents reported that she had been perfectly healthy the day before vaccination.

Past medical history revealed that the patient had been born at 31 weeks' gestation after premature rupture of the membranes; maternal fever was documented during delivery. She was hospitalized in the neonatal intensive care unit and treated with empiric antibiotics for 3 days pending blood culture results. The rest of her hospitalization was uneventful, and she was discharged at the age of 5 weeks in good medical condition.

At the present admission to the other hospital, bacterial meningitis was suspected on the basis of abnormal cerebrospinal fluid (CSF) cell count (2358/mm^3, with neutrophil predominance 60%), protein, and glucose (235 mg/dL, 1 mg/dL, resp.) despite negative findings on

direct microscopy of a CSF sample. Empiric treatment with ceftriaxone, vancomycin, and dexamethasone was started. Two days later, both blood and CSF cultures grew *Haemophilus influenzae*, which was identified as type b using latex agglutination-based antigen detection test. The patient's clinical status gradually improved over the next 4 days, when a secondary fever was noted in addition to new-onset seizures. Treatment with phenobarbital was initiated, and the patient was transferred to our tertiary medical center.

At admission to our department, magnetic resonance imaging (MRI) study revealed subdural fluid collections in the posterior fossa and around the hemispheres. Given the patient's clinical and neurological deterioration as well as the high levels of inflammatory markers, a tentative diagnosis of subdural empyema was made. The patient was transferred to the neurosurgery department where she underwent bilateral craniotomy. Findings included a subdural empyema with severe brain edema. The empyema was drained. The antibiotic treatment was continued and combined with anticonvulsant and supportive treatment, leading to gradual improvement.

The patient was discharged from our institute after 20 days, during which she received ceftriaxone. On her discharge, she was clinically stable and had normal findings on neurologic examination except for mild hypertonicity of the left arm and mild left torticollis. On follow-up visits, 2 months later and at age 1 year, brainstem-evoked response audiometry (BERA) was within normal range. There was a mild global developmental delay with normal findings on neurologic examination.

2.2. Case 2. A 5-month-old boy presented to our hospital with fever, apathy, vomiting, and diarrhea of 24-hour duration. All symptoms began 6 days after he received the second dose of the Infanrix-IPV+Hib vaccine. His parents reported that he had been perfectly healthy on the day before vaccination.

Past medical history was unremarkable. The patient was born after a normal term pregnancy and vaginal delivery. He received the first dose of Infanrix-IPV+Hib vaccine at age of 2 months without adverse events.

At admission, the patient was febrile and apathetic, with grunting respiration and a bulging fontanel. Lumbar puncture revealed a white blood cell count of 4,000 cells/mm^3, 95% segmented neutrophils, and glucose level of 8.4 mg/dL (protein level was not calculated because of technical problem). Gram staining of the CSF was negative. Empiric treatment with ceftriaxone, vancomycin, and dexamethasone was started. After 36 hours, blood culture grew *Haemophilus influenzae*, which was later identified as type b using latex agglutination-based antigen detection test.

Over the next days, the patient continued treatment with ceftriaxone, with gradual improvement. BERA study was normal. He was discharged home after 11 days in excellent condition, with no neurologic deficits.

3. Discussion

The Hib vaccine targets the organism's capsular polysaccharide, polyribosylribitol phosphate (PRP). To increase immunogenicity and induce immune memory, several conjugate vaccines were developed through covalent linkage of PRP to a carrier protein. Four conjugated vaccines were found safe and were introduced into routine immunization programs worldwide [1].

While the introduction of conjugate vaccine against Hib has had a substantial impact on Hib infection, over the past 20 years, sparse reports of cases of invasive disease after Hib vaccination have been published [3–5]. Booy et al. [3] investigated all cases of invasive Hib infection that occurred over a 3-year period in children in the United Kingdom after they received at least one dose of the Hib-conjugate vaccine. They identified two kinds of vaccine failures: apparent (early) and true (late). True failures were defined as Hib invasive disease occurring either >1 week after a child up to the age of 12 months received at least two doses of the vaccine, or >2 weeks after a single dose was received by a child >12 months of age. Hib invasive infections that occurred within one week after the administration of one or two doses of vaccine were considered apparent vaccine failures. Thus, in the present report, both cases represent apparent (early) vaccine failures.

The "apparent vaccine failure" was a known phenomenon of the early polysaccharide vaccine [6], but relatively rare when attributed to conjugate vaccine. In Booy's work [3], they reported of 46 apparent vaccine failures out of the 164 cases of invasive disease among the entire population of United Kingdom vaccinated children. Singleton et al. reviewed data from Alaska's Statewide Disease Surveillance conducted during 1980–2004 [4]. Study population included 103,000 children younger than 10 years of age. They reported of 3 early vaccine failures out of 44 cases of invasive disease in immunized children. Cowgill et al. reviewed hospitalization data of a main district hospital in Kenya and reported of 24 cases of invasive disease in immunized children, 12 of them early failures [5].

Already in 1901, Wright [7] coined the term "negative phase" to describe the decrease in bactericidal activity; he observed 1 to 21 days after administration of typhoid vaccine. This phenomenon of postimmunization provocative disease was also confirmed in early studies of conjugated and unconjugated Hib vaccines which reported that subjects with preexisting anticapsular antibodies showed a decrease in antibody concentrations after immunization [8, 9]. The nadir in antibody decline was reached 2-3 days after immunization, and concentrations normalized by day 7. The magnitude of the decline was negatively correlated with the preimmunization concentration [9]. This decrease is presumed to occur with all 4 available Hib conjugate vaccines [9]. Some authors attributed these findings to the formation of a complex between the vaccine antigens and the preexisting serum antibodies, which induces a transient decline in antibody concentration [10]. This could pose a risk of invasive disease if it occurs during a period of asymptomatic colonization with Hib [10].

In order to understand whether the individual having received the Hib vaccine is adequately protected against the organism, the level of anti-PRP antibodies should be assessed. The exact mechanism underlying the invasive infection in our patients could not be determined because

the concentration of Hib antibodies was not measured in either case before or after immunization. However, these cases are reported to serve as a reminder to clinicians of the risk, albeit rare, of invasive Hib disease in the short period after successful immunization. Clinicians should bear this possibility in mind when starting empiric antibiotic treatment in children who present with signs of infection within a week of receiving the vaccine. Large-scale studies that focus on this time frame are still needed.

Vaccines linked to mental disorders by Yale study

KEVIN WANG | 1:18 AM, FEB 21, 2017
STAFF REPORTER

A recent Yale study has called into question the safety of vaccines and could lend fuel to anti-vaccine advocates like Robert F. Kennedy Jr., who has already written a piece covering the study on the news site EcoWatch.

The study, published last month in the journal Frontiers in Psychiatry, reports that patients diagnosed with neuropsychiatric disorders like obsessive-compulsive disorder and anorexia nervosa were more likely to have received vaccinations three months prior to their diagnoses. Though the collaboration between researchers at Pennsylvania State University and the Yale Child Study Center yielded results that seem to dispute the safety of vaccines, the authors asserted that the study needs replication on a larger scale and does not establish a causal relationship between vaccines and neuropsychiatric disorders.

"There's a fair amount of interest in the vaccine safety question, so let's try to be critical and do further studies that will help examine this issue in a more thorough way," said James Leckman, professor of pediatrics and one of the study's five authors.

Using information from a health insurance claims database, Leckman and his co-authors examined the correlations between specific vaccines and various neurological disorders in six- to 15-year-old children. Children with open wounds and broken bones were used as the two control groups.

While only about 10 percent of children with open wounds had received vaccinations, vaccines had been given to over 20 percent of children later diagnosed with anorexia. Higher numbers of vaccinated children were also found among those who were diagnosed with OCD, anxiety disorder and ADHD as soon as three months after their vaccinations.

Other findings in the study, however, reveal that these correlational results should be taken with a grain of salt.

The broken bone control group also included a higher percentage of vaccinated children, though not as high as that of the anorexia group. Furthermore, vaccinations were more likely to be associated with a lower incidence of major depression and bipolar disorder.

The researchers found correlations for one vaccine in particular: the influenza vaccine, which was associated with higher rates of OCD, anorexia, anxiety disorder and tic disorder.

A biological explanation for these correlations has not been found, but a potential mechanism could lie in the body's immune response to vaccines, the study suggested.

Vaccines work by prodding the immune system to produce antibodies against viruses and bacteria, thus priming the body against these pathogens before they enter it. Some antibodies, however, can react against not only the intended pathogen proteins, but also against human proteins — a phenomenon called cross-reactivity. A 2015 study published in Science Translational Medicine discovered that antibodies elicited by the Pandemrix influenza vaccine cross-reacted with a human brain protein — hypocretin receptor 2.

Autoimmunity, in which antibodies attack human proteins, is also known to play a critical role in normal brain development, Leckman noted. According to Leckman, if children were experiencing inflammation — a process that promotes autoimmunity — at the time of vaccination, the combination of inflammation and vaccination could have deleterious effects on brain development. Such data on vaccination timing was not included in the database on which the study was based.

Another biological explanation could involve genetic factors, Leckman said. Prior studies in Scandinavian countries and China found that the H1N1 influenza vaccine was associated with narcolepsy. The influence of multiple genes found in specific populations could be responsible, he added.

Yale professor of pathology John Rose suggested that the act of vaccine administration, rather than the vaccine itself, could even have an effect on neuropsychiatric development, recalling his childhood experience of being one of the first children to receive the polio vaccine.

"We had to line up in school, and we were getting needles stuck in our arms," Rose said. "That kind of trauma could be leading to these kinds of neuropsychiatric disease. The age range of the children in the study is quite sensitive."

Rose, who developed a vaccine template that was used for the development of the current Ebola vaccine, said he trusts the current process of drug development to establish safety measures for vaccines. On average, a vaccine takes 15–20 years to be fully approved, Rose said.

Leckman said the accuracy of the diagnoses reported by the administrative database could also be questioned.

John Treanor, chief of infectious diseases at the University of Rochester Medical Center, voiced concerns about the database, citing issues of immeasurable confounding variables and the extent to which the control groups actually serve as effective controls. Nevertheless, he emphasized the importance of vaccine safety and further research to understand it.

Rose expressed concern that the study would "activate anti-vaccine people in a very serious way" and agreed with the study's assertion that the results are very preliminary and do not establish a cause and effect relationship. Animal models, Leckman noted, could help establish such a cause and effect relationship by allowing researchers to manipulate and control for multiple variables.

Even the authors noted that the results of the study are too inconclusive to warrant any reconfiguration of public health strategies.

"Given the modest magnitude of these findings in contrast to the clear public health benefits of the timely administration of vaccines in preventing mortality and morbidity in childhood infectious diseases, we encourage families to maintain vaccination schedules according to [the Centers for Disease Control and Prevention] guidelines," they wrote in the study.

Temporal Association of Certain Neuropsychiatric Disorders Following Vaccination of Children and Adolescents: A Pilot Case-Control Study.

Leslie DL[1], Kobre RA[2], Richmand BJ[2], Aktan Guloksuz S[2], Leckman JF[2].

Author information

Abstract

BACKGROUND: Although the association of the measles, mumps, and rubella vaccine with autism spectrum disorder has been convincingly disproven, the onset of certain brain-related autoimmune and inflammatory disorders has been found to be temporally associated with the antecedent administration of various vaccines. This study examines whether antecedent vaccinations are associated with increased incidence of obsessive-compulsive disorder (OCD), anorexia nervosa (AN), anxiety disorder, chronic tic disorder, attention deficit hyperactivity disorder, major depressive disorder, and bipolar disorder in a national sample of privately insured children.

METHODS: Using claims data, we compared the prior year's occurrence of vaccinations in children and adolescents aged 6-15 years with the above neuropsychiatric disorders that were newly diagnosed between January 2002 and December 2007, as well as two control conditions, broken bones and open wounds. Subjects were matched with controls according to age, gender, geographical area, and seasonality. Conditional logistic regression models were used to determine the association of prior vaccinations with each condition.

RESULTS: Subjects with newly diagnosed AN were more likely than controls to have had any vaccination in the previous 3 months [hazard ratio (HR) 1.80, 95% confidence interval 1.21-2.68]. Influenza vaccinations during the prior 3, 6, and 12 months were also associated with incident diagnoses of AN, OCD, and an anxiety disorder. Several other associations were also significant with HRs greater than 1.40 (hepatitis A with OCD and AN; hepatitis B with AN; and meningitis with AN and chronic tic disorder).

CONCLUSION: This pilot epidemiologic analysis implies that the onset of some neuropsychiatric disorders may be temporally related to prior vaccinations in a subset of individuals. These findings warrant further investigation, but do not prove a causal role of antecedent infections or vaccinations in the pathoetiology of these conditions. Given the modest magnitude of these findings in contrast to the clear public health benefits of the timely administration of vaccines in preventing mortality and morbidity in childhood infectious diseases, we encourage families to maintain vaccination schedules according to CDC guidelines.

ABSTRACT

Go to:

We report the case of a child presenting with nonfebrile seizures 6 and 13 days after the first vaccination with a measles, mumps, rubella, and varicella (MMRV) combination vaccine. Measles virus RNA was detected in the patient's serum, throat, and urine. Genotyping revealed the Schwarz vaccine virus strain.

CASE REPORT

Go to:

An 11-month-old boy was presented to the pediatric unit after experiencing three seizures in the morning of the same day. The seizures were initiated by a sharp outcry with symmetric tonic-clonic movement of the arms and legs. During the seizures, the child was not reacting to his mother and had cyanotic lips. Seizures stopped spontaneously, without the administration of anticonvulsants, after approximately 1 to 2 min. Immediately after the seizures, body temperature, as measured by the mother as well as by the emergency physician, was not elevated (37.3°C). Upon admission, the child was sleepy but conscious and without signs of meningitis. The child had a slight rash on his trunk and pale skin color; otherwise, the clinical examination was unremarkable.

There was no history of seizures before or any other known medical conditions. Six days before the seizure, the first vaccination with the regular measles, mumps, rubella, and varicella (MMRV) vaccine (Priorix-Tetra; GlaxoSmithKline) was performed. In the meantime, there were no signs of infection or fever. All blood parameters on admission were unremarkable except slight leukopenia of 4.3×10^3/μl (normal range, 6.0×10^3 to 17.0×10^3/μl). All values determined by testing the cerebrospinal fluid (CSF) taken on admission were within the range of normal (CSF protein, 221 mg/liter [normal range, 150 to 450 mg/liter]; glucose, 64 mg/dl [normal range, 50 to 75 mg/dl]; lactate, 1.4 mmol/liter [normal range, 1.2 to 2.1 mmol/liter]; leukocyte count, 2 cells/μl [normal, <4 cells/μl]; erythrocyte count, 0 cells/μl [normal, 0/μl]). CSF tested negative by PCR or reverse transcription (RT)-PCR for herpes simplex viruses 1 and 2, varicella-zoster virus, rubella virus, mumps virus, and measles virus (MeV) (Table 1). A cranial magnetic resonance scan revealed no pathological findings. In a blood sample and a throat swab taken upon admission as well as in a urine sample collected the following day, MeV RNA was detected by real-time RT-PCR by amplifying a 114-nucleotide fragment of the MeV nucleoprotein N gene.

[c]Specimen collected 6 days postvaccination.
[d]Specimen collected 7 days postvaccination.

Viral concentration was low in serum and urine but remarkably higher in the throat swab. Genotyping by amplification of a total of 507 nucleotides of the variable genomic region of the MeV nucleoprotein N gene was performed by using one nested and two heminested PCRs and revealed an MeV genotype A virus. The amplified sequence included the 450 nucleotides encoding the C-terminal 150 amino acids of the MeV nucleoprotein N; this is the minimum amount of data required for determining the MeV genotype, as recommended by the WHO (1). The MeV nucleotide sequence was identical to that of the Schwarz MeV vaccine strain (Fig. 1).

Fig 1

Strategy for identification and genotyping of the measles virus (MeV). (A) Scheme of the MeV genome. The conserved and variable regions used for MeV virus screening and genotyping, respectively, are indicated with arrows. (B) Comparison of the nucleotide sequence for the 507-bp MeV genome fragment obtained from the case patient by the genotyping RT-PCRs (upper rows) and the sequence of the Schwarz MeV vaccine strain (lower rows) (GenBank accession no. FJ211590) using the BLAST algorithm (http://www.ncbi.nlm.nih.gov/blast). Numbers before and after each row refer to the nucleotide position of the respective nucleotide sequence. The minimum requirement for MeV genotyping as defined by WHO within the sequenced genome fragment is indicated in blue.

No IgG antibodies against measles, mumps, and rubella viruses were detectable upon admission (detection of MeV antibodies was performed by IgG and IgM enzyme-linked immunosorbent assay [ELISA; Enzygnost anti-measles virus/IgG

and Enzygnost anti-measles virus/IgM; Siemens Healthcare Diagnostics, Eschborn, Germany]).

After an unremarkable hospital course, a fourth seizure episode occurred on the 13th day after the vaccination, while the child was still in the hospital. While the seizures did not fulfill all criteria of a provoked seizure due to the absence of fever, anti-epileptic treatment with levetiracetam was started. The remaining course of hospitalization was uneventful, and the child was discharged on the 9th day of hospitalization in good health. Temperature was measured regularly during the complete course of disease and was elevated only once, up to 38.3°C, on the 3rd day of hospitalization; however, no seizure was observed in association with this episode.

Regular follow-up visits have not revealed any signs of epilepsy so far, and now, more than 1 year after the vaccination, the child remains well. The therapy with levetiracetam was continued without any side effects. In a blood sample taken 3 months after the vaccination, high antibody values against mumps, measles, and rubella viruses were found, but no antibodies against varicella-zoster virus could be detected.

MeV is one of the most contagious infectious diseases in humans and among the leading causes of death in children (2). Vaccination with live attenuated measles vaccine is the most effective measure for control and eradication (3, 4). Most vaccines used today are based on the Schwarz vaccine strain (genotype A) (5).

Fever is the most common complication of immunization and occurs most often after administration of live attenuated vaccines, toxin-containing vaccines, or whole-cell preparations (6). Adverse events after vaccination against measles, mumps, rubella, and varicella are generally mild. Besides a local reaction at the site of injection, fever, and rash, the most common neurologic adverse events are febrile seizures, commonly 7 to 10 days after vaccination (7, 8). Febrile seizures in general have a favorable outcome and are not associated with neurologic sequelae. While a higher risk for febrile seizures was observed with the MMRV combination vaccine than with the MMR vaccine (8), nonfebrile seizures in association with MMRV or MMR vaccination have not been described so far.

Therefore, a search was performed in the database of the German Federal Institute for Vaccines and Biomedicines (Paul Ehrlich Institute [PEI], Langen, Germany), which collects and evaluates the reports of adverse events, and two further cases were revealed. In the first case, a 9-year-old male experienced convulsions leading to hospitalization 14 days after he had received the second dose of MMRV (MMRVaxPro; Sanofi Pasteur MSD). His symptoms resolved (the duration of symptoms was unspecified), and the patient was discharged after 2 days of hospitalization. The second case was an 11-month-old female who presented with a tonic-clonic seizure, allergic reaction, and exanthema 1 day after having received an unspecified dose of MMRV (Priorix-Tetra; GlaxoSmithKline) on 10 February 2011. Further seizures without fever in the same child occurred on two more occasions, two and three days after having received vaccinations on 14 March 2011 against diphtheria, tetanus, pertussis, Haemophilus influenzae type b, hepatitis B, poliomyelitis (Infanrix hexa; GlaxoSmithKline), and Streptococcus pneumoniae (Synflorix; GlaxoSmithKline), without any further pathological findings noted in the hospital report. So far, it is not possible based on these cases to assess a causal relationship between nonfebrile seizures and vaccination. Further awareness is necessary to evaluate whether nonfebrile seizures temporally associated with vaccine exposure have to be considered a potential adverse effect. However, it should be stressed that all children with seizures, either febrile or nonfebrile, had a favorable outcome according to available follow-up data.

Even though live attenuated measles vaccines have been used for more than 40 years, data are scarce on the extent to which vaccine virus replicates in or is shed by vaccinees (5). Isolation of infectious vaccine virus from the blood and pharynx of vaccinated children by propagation on canine renal cell culture was successfully performed in early studies with the Edmonston strain (9), from experimentally vaccinated Cynomolgus monkeys after vaccination with the Schwarz vaccine strain (10), and in a study evaluating fever and rash appearing 3 to 9 days after measles vaccination (11). In this study, in 6 of 7 children, wild-type virus was isolated from peripheral blood leukocytes or throat swabs, suggesting vaccination during the incubation period of wild-type MeV. In only 1 of 7 patients, vaccine virus (strain Handai) was isolated from blood leukocytes, and this child had the mildest clinical course (mild fever without rash appearing on day 7 after vaccination) (11). It is not stated in the above-mentioned study if the children, in whom Edmonston vaccine virus isolation was achieved, presented with any symptoms or were asymptomatic (9). Further, Edmonston vaccine virus RNA was detected by RT-PCR 13 days after vaccination in the serum of an HIV-positive, 1-year-old boy who presented with measles-like illness 10 days after MMR vaccination (12).

For the Schwarz vaccine strain, there are two case reports about healthy children that describe demonstration of vaccine virus in the throat of a 3-year-old boy (13) and detection of vaccine virus RNA in the throat and urine of a 14-month-old child (14). The first child presented with fever, pharyngitis, and adenopathy 8 days after vaccination. MeV was isolated in cell culture from a throat swab taken 4 days after fever onset. The 14-month-old child in the second case report presented with facial erythema without fever 5 days after vaccination, followed by fever and rash 8 days after vaccination. MeV RNA was detected by RT-PCR from a throat swab taken 5 days and from a urine sample taken 6 days after the onset of fever. In both children, the virus RNA could be characterized as the Schwarz strain, and both children had a favorable follow-up. Taken together, the results from the three reports, including ours, show that Schwarz vaccine strain RNA is present in blood at least at day 6 postvaccination and is detectable in throat and urine at days 7 to 15 postvaccination. However, the clinical relevance

of detection of vaccine virus or its RNA from the different body compartments, if any, remains unclear. To the best of our knowledge, so far there are no reports of transmission of vaccine measles virus.

ACKNOWLEDGMENTS

Go to:

We thank the mother of the child for giving her informed consent and allowing us to report the details of this case. We also thank Ulrike Reber for excellent technical assistance.

We report no conflicts of interest.

Optic neuritis following diphtheria, tetanus, pertussis, and inactivated poliovirus combined vaccination: a case report

Preston O'Brien[1*] and Robert W. Wong[1,2*]

Abstract

Background: Diphtheria, tetanus, pertussis, and inactivated poliovirus combined vaccine is widely used in young children as part of a series of immunizations before they start attending school. Case studies of demyelinating conditions following administration of diphtheria, tetanus, pertussis, and polio vaccine have been reported, but none so far resulting in optic neuritis. This report further contributes to the database of central nervous system demyelinating conditions affiliated with receipt of vaccines.

Case presentation: A previously healthy 27-year-old Hispanic man presented to an emergency department with headache, periorbital pressure, pain with ocular movements, and intermittent blurred vision that developed 1 day after administration of the diphtheria, tetanus, pertussis, and inactivated poliovirus combined vaccine. A diagnosis of optic neuritis was made via ophthalmic examination with fundus photography and automated Humphrey visual field analysis. His vision recovered following treatment with high-dose intravenously administered methylprednisolone followed by a tapered dose of orally administered prednisolone.

Conclusions: Although the association between immunizations and the onset of central nervous system demyelinating conditions is well documented, this report, to the best of our knowledge, is the first case of optic neuritis following diphtheria, tetanus, pertussis, and inactivated poliovirus combined vaccination. Inclusion of this case report in the medical community will allow for broader understanding of possible conditions that may present shortly after receipt of vaccination.

Keywords: Diphtheria, Tetanus, Pertussis, Virus, Optic neuritis

Background

Diphtheria, tetanus, pertussis, and inactivated poliovirus combined vaccine (DTaP-IPV) is widely used in young children as part of a series of immunizations before they start attending school. Although clinical trials have shown an excellent safety profile [1], there have been reports of encephalitis, angioneurotic edema, seizures, and serious local reactions following its administration [1, 2]. Although cases of central nervous system (CNS) demyelinating conditions following DTaP-IPV vaccine have been reported [3], to the best of our knowledge, we present the first case of optic neuritis.

Case presentation

A 27-year-old Hispanic man with no significant past medical history presented to an emergency department with a 5-day history of headache, pain with ocular movements, and intermittent blurred vision starting 1 day after being immunized with DTaP-IPV. Magnetic resonance imaging and a magnetic resonance venogram of his brain were unremarkable. A lumbar puncture revealed a normal opening pressure and cerebrospinal fluid studies were positive for

It is our aim with the submission of this case report to the *Journal of Medical Case Reports* to present a new association between receipt of the diphtheria, tetanus, pertussis, and inactivated poliovirus combined vaccine by our patient and his presenting with optic neuritis. It is important that we make efforts to ensure that the medical community is aware of potential central nervous system demyelinating conditions coinciding with receipt of vaccines so that they can follow the observations, treatment, and precautions in dealing with similar circumstances.

Full list of author information is available at the end of the article

myelin basic protein but negative for oligoclonal bands and neuromyelitis optica autoantibody serology.

On examination, his best corrected vision was 20/100 in his right eye and 20/70 in his left eye. Intraocular pressures, pupil examination, ocular alignment, and extraocular movements were normal. Confrontational visual fields were restricted in both eyes. Posterior segment examination showed optic nerve swelling and hyperemia in both eyes (Fig. 1) and two microaneurysms in the mid periphery of his left eye. No evidence of vitritis, retinal vasculitis, or choroiditis was seen in either eye.

Serum laboratory testing showed elevated glycated hemoglobin (A1C) at 6.9%, aspartate aminotransferase (AST), and alanine aminotransferase (ALT). Other liver tests including bilirubin, alkaline phosphatase, and hepatitis serologies were normal. Tests for infectious and inflammatory etiologies including angiotensin-converting enzyme (ACE), lysozyme, antinuclear antibody (ANA), cytoplasmic antineutrophil cytoplasmic antibodies (c-ANCA), perinuclear antineutrophil cytoplasmic antibodies (p-ANCA), lupus panel, rapid plasma reagin (RPR), fluorescent treponemal antibody absorption (FTA-ABS), chest X-ray, and QuantiFERON Gold assay, which were normal. Over the next 5 days, his vision declined to counting fingers at 30.5 cm (1 foot) in both eyes. A relative afferent pupil defect and dyschromatopsia developed on the left. Automated Humphrey visual field (HVF) testing demonstrated global depression in both eyes (Fig. 2).

He was diagnosed as having DTaP-IPV vaccination-related optic neuritis and started on intravenously administered Solu-Medrol (methylprednisolone). One week later, his headache resolved and vision improved to 20/20 in his right eye and 20/25 in his left eye with less optic nerve hyperemia and swelling. He was discharged on a prednisone taper and an orally administered diabetic medication. One month later, his vision improved to 20/20 with resolution of the optic neuritis without residual visual field deficit in both eyes.

Discussion

In 2008, the DTaP-IPV vaccine was licensed and indicated for use in children of 4–6 years in age. From 2009 to 2012, a large-scale trial monitoring for adverse events found no significant increased risk of meningitis or encephalitis following DTaP-IPV [1]. Although the overall risk of developing a demyelinating CNS syndrome after vaccination is relatively low

(estimated to be 0.1%), it is not negligible [3]. Molecular mimicry from the viral proteins or the adjuvants used in the preparation of the vaccine have been suspected in the development of demyelinating disease following vaccination [3, 4]. Molecular mimicry occurs when similarities exist between proteins of viruses used in vaccinations and the components of CNS myelin which may disrupt self-tolerance and cause production of autoantibodies resulting in CNS inflammation including optic neuritis [3, 5]. Our case is consistent with other cases of post-vaccination optic neuritis, most of which develop 1–3 weeks after vaccination, typical of an immune-triggered mechanism [3].

In most cases, symptoms of optic neuritis were mostly resolved after treatment with steroids such as intravenously administered methylprednisolone followed by tapered oral prednisolone for several weeks [3, 5]. Early recognition of ocular signs and symptoms of optic neuritis following DTaP-IPV vaccination may lead to prompt treatment and preserved vision.

Conclusions

Although the association between immunizations and the onset of CNS demyelinating conditions is well documented, this report, to the best of our knowledge, is the first case of optic neuritis following DTaP-IPV vaccination. Inclusion of this case report in the medical community will allow for broader understanding of possible conditions that may present shortly after receipt of vaccination.

Optic neuritis in pregnancy after Tdap vaccination: Report of two cases.

Cabrera-Maqueda JM[1], Hernández-Clares R[2], Baidez-Guerrero AE[1], Pío-Rendón JIB[3], Fernández JJM[1].

Author information

Abstract

Two pregnant women developed one-eye blurring vision within three weeks after Tdap vaccination. Neurophtalmologic and MR examination confirmed an unilateral optic neuritis without evidence of underlying disease. Both patients had a full recovery, one after intravenous metilprednisolone. This is the first report of optic neuritis related with Tdap vaccination in pregnancy.

Abstract

Though rare, neurological serious adverse events following measles immunization are well documented in scientific literature. However, we could retrieve only 7 published reports of optic neuritis following measles/measles containing vaccines. We report a case of bilateral optic neuritis that developed within 24 h of administration of monovalent measles vaccine in an eight-year-old male child during special measles immunization campaign in India.

Adverse neurologic reactions after both doses of pandemic H1N1 influenza vaccine with optic neuritis and demyelination.

Lapphra K[1], Huh L, Scheifele DW.

Author information

Abstract

When a neurologic condition develops after vaccination of a patient, the causal relationship is difficult to determine. We report an unusual case in which neurologic signs occurred in a previously healthy child after both doses of H1N1 2009 influenza vaccine, culminating in bilateral optic neuritis and disseminated encephalomyelitis. A causal association is more likely with repeated injury following influenza vaccination.

The role of infection and vaccination in the genesis of optic neuritis and multiple sclerosis in children.

Riikonen R[1].

Author information

Abstract

This article describes the association between previous infection and/or vaccination and the development of optic neuritis (ON) in 18 children. Ten of these children subsequently developed clinically definite multiple sclerosis (MS), while in 8 patients a clinically definite etiology could not be confirmed. Vaccination preceded the first ON attack in 6 patients, all but one of whom subsequently developed MS. It also preceded subsequent demyelinating events in 6 patients. Ten of the patients had a bacterial or viral infection within the 2 weeks prior to the first symptoms of ON. Intrathecal antibody synthesis against 2 or more viruses could be shown in 5 out of 8 patients studied; 5 out of 6 patients had oligoclonal antibodies in CSF and 12 out of 16 patients a high IgG index. Neither intrathecal antibody synthesis against 2 or more viruses nor elevated IgG indexes could be found in the control patients. Measles and mumps occurred at a significantly later age in the children who subsequently developed MS than in the control children, and these patients had significantly more events that might have impaired the blood-brain barrier than the controls. These results indicate that immunological events leading to MS may be triggered during childhood. Vaccination and infection often precede ON in childhood. Intrathecal viral antibody production can occur already in childhood at the time of the first symptoms of MS.

Infant mortality rates regressed against number of vaccine doses routinely given: Is there a biochemical or synergistic toxicity?

Neil Z Miller and Gary S Goldman

Abstract

The infant mortality rate (IMR) is one of the most important indicators of the socio-economic well-being and public health conditions of a country. The US childhood immunization schedule specifies 26 vaccine doses for infants aged less than 1 year—the most in the world—yet 33 nations have lower IMRs. Using linear regression, the immunization schedules of these 34 nations were examined and a correlation coefficient of $r = 0.70$ ($p < 0.0001$) was found between IMRs and the number of vaccine doses routinely given to infants. Nations were also grouped into five different vaccine dose ranges: 12–14, 15–17, 18–20, 21–23, and 24–26. The mean IMRs of all nations within each group were then calculated. Linear regression analysis of unweighted mean IMRs showed a high statistically significant correlation between increasing number of vaccine doses and increasing infant mortality rates, with $r = 0.992$ ($p = 0.0009$). Using the Tukey-Kramer test, statistically significant differences in mean IMRs were found between nations giving 12–14 vaccine doses and those giving 21–23, and 24–26 doses. A closer inspection of correlations between vaccine doses, biochemical or synergistic toxicity, and IMRs is essential.

Introduction

The infant mortality rate (IMR) is one of the most important measures of child health and overall development in countries. Clean water, increased nutritional measures, better sanitation, and easy access to health care contribute the most to improving infant mortality rates in unclean, undernourished, and impoverished regions of the world.[1–3] In developing nations, IMRs are high because these basic necessities for infant survival are lacking or unevenly distributed. Infectious and communicable diseases are more common in developing countries as well, though sound sanitary practices and proper nutrition would do much to prevent them.[1]

The World Health Organization (WHO) attributes 7 out of 10 childhood deaths in developing countries to five main causes: pneumonia, diarrhea, measles, malaria, and malnutrition—the latter greatly affecting all the others.[1] Malnutrition has been associated with a decrease in immune function. An impaired immune function often leads to an increased susceptibility to infection.[2] It is well established that infections, no matter how mild, have adverse effects on nutritional status. Conversely, almost any nutritional deficiency will diminish resistance to disease.[3]

Despite the United States spending more per capita on health care than any other country,[4] 33 nations have better IMRs. Some countries have IMRs that are less than half the US rate: Singapore, Sweden, and Japan are below 2.80. According to the Centers for Disease Control and Prevention (CDC), "The relative position of the United States in comparison to countries with the lowest infant mortality rates appears to be worsening."[5]

CIA. Country comparison: infant mortality rate (2009). *The World Factbook*. www.cia.gov (Data last updated 13 April 2010).[8]

There are many factors that affect the IMR of any given country. For example, premature births in the United States have increased by more than 20% between 1990 and 2006. Preterm babies have a higher risk of complications that could lead to death within the first year of life.[6] However, this does not fully explain why the United States has seen little improvement in its IMR since 2000.[7]

Nations differ in their immunization requirements for infants aged less than 1 year. In 2009, five of the 34 nations with the best IMRs required 12 vaccine doses, the least amount, while the United States required 26 vaccine doses, the most of any nation. To explore the correlation between vaccine doses that nations routinely give to their infants and their infant mortality rates, a linear regression analysis was performed.

Methods and design

Infant mortality

The infant mortality rate is expressed as the number of infant deaths per 1000 live births. According to the US Central Intelligence Agency (CIA), which keeps accurate, up-to-date infant mortality statistics throughout the world, in 2009 there were 33 nations with better infant mortality rates than the United States (Table 1).[8] The US infant mortality rate of 6.22 infant deaths per 1000 live births ranked 34th.

Immunization schedules and vaccine doses

A literature review was conducted to determine the immunization schedules for the United States and all 33 nations with better IMRs than the United States.[9,10] The total number of vaccine doses specified for infants aged less than 1 year was then determined for each country (Table 2). A vaccine dose is an exact amount of medicine or drug to be administered. The number of doses a child receives should not be confused with the number of 'vaccines' or 'injections' given. For example, DTaP is given as a single injection but contains three separate vaccines (for diphtheria, tetanus, and pertussis) totaling three vaccine doses.

Nations organized into data pairs

The 34 nations were organized into data pairs consisting of total number of vaccine doses specified for their infants and IMRs. Consistent with biostatistical conventions, four nations—Andorra, Liechenstein, Monaco, and San Marino—were excluded from the dataset because they each had fewer than five infant deaths, producing extremely wide confidence intervals and IMR instability. The remaining 30 (88%) of the data pairs were then available for analysis.

Nations organized into groups

Nations were placed into the following five groups based on the number of vaccine doses they routinely give their infants: 12–14, 15–17, 18–20, 21–23, and 24–26 vaccine doses. The unweighted IMR means of all nations as a function of the number of vaccine

Table 2. Summary of International Immunization Schedules: vaccines recommended/required prior to one year of age in 34 nations

Nation	Vaccines prior to one year of age	Total[b] doses	Group (range of doses)
Sweden	DTaP (2), Polio (2), Hib (2), Pneumo (2)	12	1 (12–14)

Ireland	DTaP (3), Polio (3), Hib (3), HepB (3), Pneumo (2), MenC (2), BCG	23	
Greece	DTaP (3), Polio (3), Hib (3), HepB (3), Pneumo (3), MenC (2)	23	
Monaco[a]	DTaP (3), Polio (3), Hib (3), HepB (3), Pneumo (3), HepA, BCG	23	
Netherlands	DTaP (4), Polio (4), Hib (4), Pneumo (4)	24	5 (24–26)
Canada	DTaP (3), Polio (3), Hib (3), HepB (3), Pneumo (3), MenC (2), Flu	24	
Australia	DTaP (3), Polio (3), Hib (3), HepB (4), Pneumo (3), Rota (2)	24	
United States	DTaP (3), Polio (3), Hib (3), HepB (3), Pneumo (3), Rota (3), Flu (2)	26	

[a] These four nations were excluded from the analysis because they had fewer than five infant deaths.
[b] DTaP is administered as a single shot but contains three separate vaccines (for diphtheria, tetanus, and pertussis). Thus, DTaP given three times in infancy is equivalent to nine vaccine doses.
Immunization schedules are for 2008–2009.[9,10]

doses were analyzed using linear regression. The Pearson correlation coefficient (r) and coefficient of determination (r^2) were calculated using GraphPad Prism, version 5.03 (GraphPad Software, San Diego, CA, USA, www.graphpad.com). Additionally, the F statistic and corresponding p values were computed to test if the best fit slope was statistically significantly non-zero. The Tukey-Kramer test was used to determine whether or not the mean IMR differences between the groups were statistically significant. Following the one-way ANOVA (analysis of variance) results from the Tukey-Kramer test, a post test for the overall linear trend was performed.

Results

Nations organized into data pairs

A scatter plot of each of the 30 nation's IMR versus vaccine doses yielded a linear relationship with a correlation coefficient of 0.70 (95% CI, 0.46–0.85) and $p < 0.0001$ providing evidence of a positive correlation: IMR and vaccine doses tend to increase together.

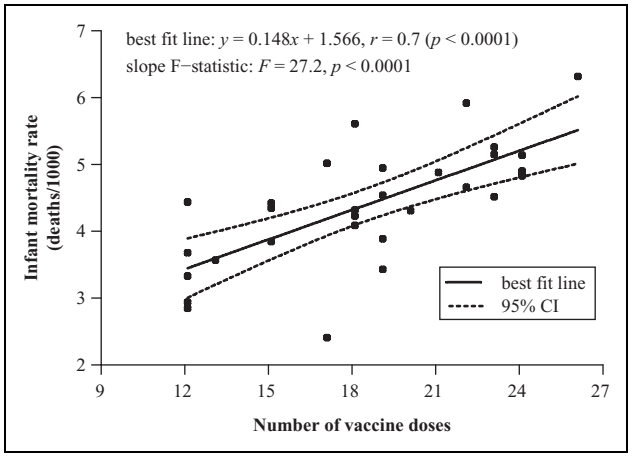

Figure 1. 2009 Infant mortality rates and number of vaccine doses for 30 nations.

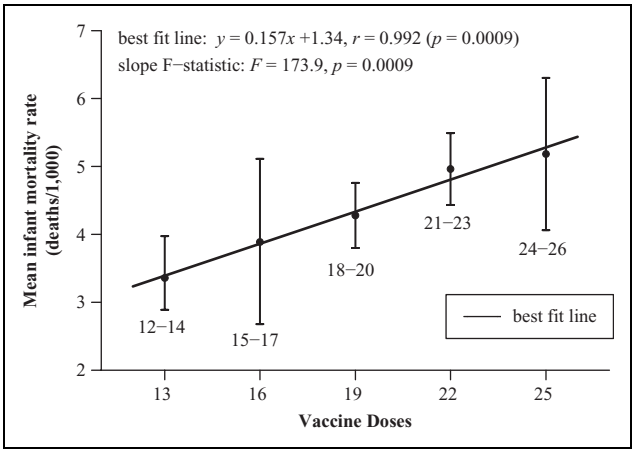

Figure 2. 2009 Mean infant mortality rates and mean number of vaccine doses (five categories).

The F statistic applied to the slope [0.148 (95% CI, 0.090–0.206)] is significantly non-zero, with $F = 27.2$ ($p < 0.0001$; Figure 1).

Nations organized into groups

The unweighted mean IMR of each category was computed by simply summing the IMRs of each nation comprising a group and dividing by the number of nations in that group. The IMRs were as follows: 3.36 (95% CI, 2.74–3.98) for nations specifying 12–14 doses (mean 13 doses); 3.89 (95% CI, 2.68–5.12) for 15–17 doses (mean 16 doses); 4.28 (95% CI, 3.80–4.76) for 18–20 doses (mean 19 doses); 4.97 (95% CI, 4.44–5.49) for 21–23 doses (mean 22 doses); 5.19 (95% CI, 4.06–6.31) for 24-26 doses (mean 25 doses; Figure 2). Linear regression analysis yielded an equation of the best fit line, $y = 0.157x + 1.34$ with $r = 0.992$ ($p = 0.0009$) and $r^2 = 0.983$. Thus, 98.3% of the variation in mean IMRs is explained by the linear model. Again, the F statistic yielded a significantly non-zero slope, with $F = 173.9$ ($p = 0.0009$).

The one-way ANOVA using the Tukey-Kramer test yielded $F = 650$ with $p = 0.001$, indicating the five mean IMRs corresponding to the five defined dose categories are significantly different ($r^2 = 0.510$). Tukey's multiple comparison test found statistical significance in the differences between the mean IMRs of those nations giving 12–14 vaccine doses and (a) those giving 21–23 doses (1.61, 95% CI, 0.457–2.75) and (b) those giving 24–26 doses (1.83, 95% CI, 0.542–3.11).

Discussion

Basic necessities for infant survival

It is instructive to note that many developing nations require their infants to receive multiple vaccine doses and have national vaccine coverage rates (a percentage of the target population that has been vaccinated) of 90% or better, yet their IMRs are poor. For example, Gambia requires its infants to receive 22 vaccine doses during infancy and has a 91%–97% national vaccine coverage rate, yet its IMR is 68.8. Mongolia requires 22 vaccine doses during infancy, has a 95%–98% coverage rate, and an IMR of 39.9.[8,9] These examples appear to confirm that IMRs will remain high in nations that cannot provide clean water, proper nutrition, improved sanitation, and better access to health care. *As developing nations improve in all of these areas a critical threshold will eventually be reached where further reductions of the infant mortality rate will be difficult to achieve because most of the susceptible infants that could have been saved from these causes would have been saved.* Further reductions of the IMR must then be achieved in areas outside of these domains. As developing nations ascend to higher socio-economic living standards, a closer inspection of all factors contributing to infant deaths must be made.

Crossing the socio-economic threshold

It appears that at a certain stage in nations' movement up the socio-economic scale—after the basic necessities for infant survival (proper nutrition, sanitation, clean water, and access to health care) have been met—a counter-intuitive relationship occurs between

the number of vaccines given to infants and infant mortality rates: nations with higher (worse) infant mortality rates give their infants, on average, more vaccine doses. This positive correlation, derived from the data and demonstrated in Figures 1 and 2, elicits an important inquiry: are some infant deaths associated with over-vaccination?

A closer inspection of infant deaths

Many nations adhere to an agreed upon International Classification of Diseases (ICD) for grouping infant deaths into 130 categories.[11–13] Among the 34 nations analyzed, those that require the most vaccines tend to have the worst IMRs. Thus, we must ask important questions: is it possible that some nations are requiring too many vaccines for their infants and the additional vaccines are a toxic burden on their health? Are some deaths that are listed within the 130 infant mortality death categories really deaths that are associated with over-vaccination? Are some vaccine-related deaths hidden within the death tables?

Sudden infant death syndrome (SIDS)

Prior to contemporary vaccination programs, 'Crib death' was so infrequent that it was not mentioned in infant mortality statistics. In the United States, national immunization campaigns were initiated in the 1960s when several new vaccines were introduced and actively recommended. For the first time in history, most US infants were required to receive several doses of DPT, polio, measles, mumps, and rubella vaccines.[14] Shortly thereafter, in 1969, medical certifiers presented a new medical term—sudden infant death syndrome.[15,16] In 1973, the National Center for Health Statistics added a new cause-of-death category—for SIDS—to the ICD. SIDS is defined as the sudden and unexpected death of an infant which remains unexplained after a thorough investigation. Although there are no specific symptoms associated with SIDS, an autopsy often reveals congestion and edema of the lungs and inflammatory changes in the respiratory system.[17] By 1980, SIDS had become the leading cause of postneonatal mortality (deaths of infants from 28 days to one year old) in the United States.[18]

In 1992, to address the unacceptable SIDS rate, the American Academy of Pediatrics initiated a 'Back to Sleep' campaign, convincing parents to place their infants supine, rather than prone, during sleep. From 1992 to 2001, the postneonatal SIDS rate dropped by an average annual rate of 8.6%. However, other causes of sudden unexpected infant death (SUID) increased. For example, the postneonatal mortality rate from 'suffocation in bed' (ICD-9 code E913.0) increased during this same period at an average annual rate of 11.2%. The postneonatal mortality rate from 'suffocation-other' (ICD-9 code E913.1-E913.9), 'unknown and unspecified causes' (ICD-9 code 799.9), and due to 'intent unknown' in the External Causes of Injury section (ICD-9 code E980-E989), all increased during this period as well.[18] (In Australia, Mitchell et al. observed that when the SIDS rate decreased, deaths attributed to asphyxia increased.[19] Overpeck et al. and others, reported similar observations.)[20,21]

A closer inspection of the more recent period from 1999 to 2001 reveals that the US postneonatal SIDS rate continued to decline, but *there was no significant change in the total postneonatal mortality rate.* During this period, the number of deaths attributed to 'suffocation in bed' and 'unknown causes,' increased significantly. According to Malloy and MacDorman, "If death-certifier preference has shifted such that previously classified SIDS deaths are now classified as 'suffocation,' the inclusion of these suffocation deaths and unknown or unspecified deaths with SIDS deaths then accounts for about 90 percent of the decline in the SIDS rate observed between 1999 and 2001 and results in a non-significant decline in SIDS"[18] (Figure 3).

Is there evidence linking SIDS to vaccines?

Although some studies were unable to find correlations between SIDS and vaccines,[22–24] there is some evidence that a subset of infants may be more susceptible to SIDS shortly after being vaccinated. For example, Torch found that two-thirds of babies who had died from SIDS had been vaccinated against DPT (diphtheria–pertussis–tetanus toxoid) prior to death. Of these, 6.5% died within 12 hours of vaccination; 13% within 24 hours; 26% within 3 days; and 37%, 61%, and 70% within 1, 2, and 3 weeks, respectively. Torch also found that unvaccinated babies who died of SIDS did so most often in the fall or winter while vaccinated babies died most often at 2 and 4 months—the same ages when initial doses of DPT were given to infants. He concluded that DPT "may be a generally unrecognized major cause of sudden infant and early childhood death, and that the risks of immunization may outweigh its potential benefits. A need for re-evaluation and possible modification of

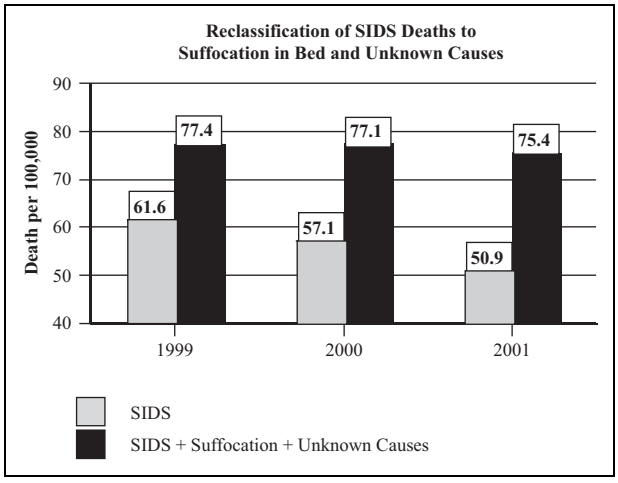

Figure 3. Reclassification of sudden infant death syndrome (SIDS) deaths to suffocation in bed and unknown causes. The postneonatal SIDS rate appears to have declined from 61.6 deaths (per 100,000 live births) in 1999 to 50.9 in 2001. However, during this period there was a significant increase in postneonatal deaths attributed to suffocation in bed and due to unknown causes. When these sudden unexpected infant deaths (SUIDs) are combined with SIDS deaths, the total SIDS rate remains relatively stable, resulting in a non-significant decline.

current vaccination procedures is indicated by this study."[25] Walker et al. found "the SIDS mortality rate in the period zero to three days following DPT to be 7.3 times that in the period beginning 30 days after immunization."[26] Fine and Chen reported that babies died at a rate nearly eight times greater than normal within 3 days after getting a DPT vaccination.[27]

Ottaviani et al. documented the case of a 3-month-old infant who died suddenly and unexpectedly shortly after being given six vaccines in a single shot: "Examination of the brainstem on serial sections revealed bilateral hypoplasia of the arcuate nucleus. The cardiac conduction system presented persistent fetal dispersion and resorptive degeneration. This case offers a unique insight into the possible role of hexavalent vaccine in triggering a lethal outcome in a vulnerable baby." Without a full necropsy study in the case of sudden, unexpected infant death, at least some cases linked to vaccination are likely to go undetected.[28]

Reclassified infant deaths

It appears as though some infant deaths attributed to SIDS may be vaccine related, perhaps associated with biochemical or synergistic toxicity due to over-vaccination. Some infants' deaths categorized as 'suffocation' or due to 'unknown and unspecified causes' may also be cases of SIDS reclassified within the ICD. Some of these infant deaths may be vaccine related as well. This trend toward reclassifying ICD data is a great concern of the CDC "because inaccurate or inconsistent cause-of-death determination and reporting hamper the ability to monitor national trends, ascertain risk factors, and design and evaluate programs to prevent these deaths."[29] If some infant deaths are vaccine related and concealed within the various ICD categories for SUIDs, is it possible that other vaccine-related infant deaths have also been reclassified?

Of the 34 nations that have crossed the socio-economic threshold and are able to provide the basic necessities for infant survival—clean water, nutrition, sanitation, and health care—several require their infants to receive a relatively high number of vaccine doses and have relatively high infant mortality rates. These nations should take a closer look at their infant death tables to determine if some fatalities are possibly related to vaccines though reclassified as other causes. Of course, all SUID categories should be re-inspected. Other ICD categories may be related to vaccines as well. For example, a new live-virus orally administered vaccine against rotavirus-induced diarrhea—Rotarix®—was licensed by the European Medicine Agency in 2006 and approved by the US Food and Drug Administration (FDA) in 2008. However, in a clinical study that evaluated the safety of the Rotarix vaccine, *vaccinated babies died at a higher rate than non-vaccinated babies*—mainly due to a statistically significant increase in pneumonia-related fatalities.[30] (One biologically plausible explanation is that natural rotavirus infection might have a protective effect against respiratory infection.)[31] Although these fatalities appear to be vaccine related and raise a nation's infant mortality rate, medical certifiers are likely to misclassify these deaths as pneumonia.

Several additional ICD categories are possible candidates for incorrect infant death classifications: unspecified viral diseases, diseases of the blood, septicemia, diseases of the nervous system, anoxic brain damage, other diseases of the nervous system, diseases of the respiratory system, influenza, and unspecified diseases of the respiratory system. All of these selected causes may be repositories of vaccine-related infant deaths reclassified as common fatalities. All nations—rich and poor, industrialized and developing—have an obligation to determine whether their immunization schedules are achieving

their desired goals. Progress on reducing infant mortality rates should include monitoring vaccine schedules and medical certification practices to ascertain whether vaccine-related infant deaths are being reclassified as ordinary mortality in the ICD.

How many infants can be saved with an improved IMR?

Slight improvements in IMRs can make a substantial difference. In 2009, there were approximately 4.5 million live births and 28,000 infant deaths in the United States, resulting in an infant mortality rate of 6.22/1000. If health authorities can find a way to reduce the rate by 1/1000 (16%), the United States would rise in international rank from 34th to 31st and about 4500 infants would be saved.

Limitations of study and potential confounding factors

This analysis did not adjust for vaccine composition, national vaccine coverage rates, variations in the infant mortality rates among minority races, preterm births, differences in how some nations report live births, or the potential for ecological bias. A few comments about each of these factors are included below.

Vaccine composition

This analysis calculated the total number of vaccine doses received by children but did not differentiate between the substances, or quantities of those substances, in each dose. Common vaccine substances include antigens (attenuated viruses, bacteria, toxoids), preservatives (thimerosal, benzethonium chloride, 2-phenoxyethanol, phenol), adjuvants (aluminum salts), additives (ammonium sulfate, glycerin, sodium borate, polysorbate 80, hydrochloric acid, sodium hydroxide, potassium chloride), stabilizers (fetal bovine serum, monosodium glutamate, human serum albumin, porcine gelatin), antibiotics (neomycin, streptomycin, polymyxin B), and inactivating chemicals (formalin, glutaraldehyde, polyoxyethylene). For the purposes of this study, all vaccine doses were equally weighted.

Vaccine coverage rates

No adjustment was made for national vaccine coverage rates—a percentage of the target population that received the recommended vaccines. However, most of the nations in this study had coverage rates in the 90%–99% range for the most commonly recommended vaccines—DTaP, polio, hepatitis B, and Hib (when these vaccines were included in the schedule). Therefore, this factor is unlikely to have impacted the analyses.[9]

Minority races

It has been argued that the US IMR is poor in comparison to many other nations because African–American infants are at greater risk of dying relative to White infants, perhaps due to genetic factors or disparities in living standards. However, in 2006 the US IMR for infants of all races was 6.69 and the IMR for White infants was 5.56.[13] In 2009, this improved rate would have moved the United States up by just one rank internationally, from 34th place to 33rd place.[8] In addition, the IMRs for Hispanics of Mexican descent and Asian–Americans in the United States are significantly lower than the IMR for Whites.[6] Thus, diverse IMRs among different races in the Unites States exert only a modest influence over the United States' international infant mortality rank.

Preterm births

Preterm birth rates in the United States have steadily increased since the early 1980s. (This rise has been tied to a greater reliance on caesarian deliveries, induced labor, and more births to older mothers.) Preterm babies are more likely than full-term babies to die within the first year of life. About 12.4% of US births are preterm. In Europe, the prevalence rate of premature birth ranges from 5.5% in Ireland to 11.4% in Austria. Preventing preterm births is essential to lower infant mortality rates. However, it is important to note that some nations such as Ireland and Greece, which have very low preterm birth rates (5.5% and 6%, respectively) compared to the United States, require their infants to receive a relatively high number of vaccine doses (23) and have correspondingly high IMRs. Therefore, reducing preterm birth rates is only part of the solution to reduce IMRs.[6,32]

Differences in reporting live births

Infant mortality rates in most countries are reported using WHO standards, which do not include any reference to the duration of pregnancy or weight of the infant, but do define a 'live birth' as a baby born with any signs of life for any length of time.[12] However,

four nations in the dataset—France, the Czech Republic, the Netherlands, and Ireland—do not report live births entirely consistent with WHO standards. These countries add an additional requirement that live babies must also be at least 22 weeks of gestation or weigh at least 500 grams. If babies do not meet this requirement and die shortly after birth, they are reported as stillbirths. This inconsistency in reporting live births artificially lowers the IMRs of these nations.[32,33] According to the CDC, "There are some differences among countries in the reporting of very small infants who may die soon after birth. However, it appears unlikely that differences in reporting are the primary explanation for the United States' relatively low international ranking."[32] Nevertheless, when the IMRs of France, the Czech Republic, the Netherlands, and Ireland were adjusted for known underreporting of live births and the 30 data pairs retested for significance, the correlation coefficient improved from 0.70 to 0.74 (95% CI, 0.52–0.87).

Ecological bias

Ecological bias occurs when relationships among individuals are inferred from similar relationships observed among groups (or nations). Although most of the nations in this study had 90%–99% of their infants fully vaccinated, without additional data we do not know whether it is the vaccinated or unvaccinated infants who are dying in infancy at higher rates. However, respiratory disturbances have been documented in close proximity to infant vaccinations, and lethal changes in the brainstem of a recently vaccinated baby have been observed. Since some infants may be more susceptible to SIDS shortly after being vaccinated, and babies vaccinated against diarrhea died from pneumonia at a statistically higher rate than non-vaccinated babies, there is plausible biologic and causal evidence that the observed correlation between IMRs and the number of vaccine doses routinely given to infants should not be dismissed as ecological bias.

Conclusion

The US childhood immunization schedule requires 26 vaccine doses for infants aged less than 1 year, the most in the world, yet 33 nations have better IMRs. Using linear regression, the immunization schedules of these 34 nations were examined and a correlation coefficient of 0.70 ($p < 0.0001$) was found between IMRs and the number of vaccine doses routinely given to infants. When nations were grouped into five different vaccine dose ranges (12–14, 15–17, 18–20, 21–23, and 24–26), 98.3% of the total variance in IMR was explained by the unweighted linear regression model. These findings demonstrate a counter-intuitive relationship: *nations that require more vaccine doses tend to have higher infant mortality rates*.

Efforts to reduce the relatively high US IMR have been elusive. Finding ways to lower preterm birth rates should be a high priority. However, preventing premature births is just a partial solution to reduce infant deaths. A closer inspection of correlations between vaccine doses, biochemical or synergistic toxicity, and IMRs, is essential. All nations—rich and poor, advanced and developing—have an obligation to determine whether their immunization schedules are achieving their desired goals.

Simultaneous sudden infant death syndrome.

Balci Y[1], Tok M, Kocaturk BK, Yenilmez C, Yirulmaz C.

Author information

Abstract

The simultaneous sudden deaths of twins rarely occur and therefore it has received limited attention in the medical literature. When the deaths of the twins meet the defined criteria for sudden infant death syndrome (SIDS) independently and take place within the same 24 h range it can be called as simultaneous SIDS (SSIDS). The case(s): Twin girls (3.5-month-old) were found dead by their mother in their crib, both in supine position. The infants were identical twins and delivered at a hospital by cesarean section. Both infants were healthy and did not have any serious medical history. Two days prior to the incident, the twins had received the second dose of oral polio, DPT and the first dose of hepatitis B vaccines and they had fever on the first day of the vaccination and been given teaspoonful of acetaminophen. Death scene investigation, judicial investigation, parental assessment, macroscopic and microscopic autopsy findings and the toxicological analysis did not yield any specific cause of death. The case(s) were referred to a supreme board composed of multidisciplinary medical professionals at the Institute of Forensic Medicine, Ministry of Justice, in Istanbul. The Board decided that the available data was consistent with SIDS. These SIDS case(s) are presented because twin SIDS are rare and this is the first time that a simultaneous twin SIDS have been reported in Turkey. Simultaneous SIDS cases have many implications regarding definition, diagnosis and medico-legal approach.

OFFICE OF SPECIAL MASTERS

Filed: July 10, 2017

CHASE BOATMON & MAURINA CUPID, *parents of* J.B., *deceased,*	*	PUBLISHED DECISION
	*	No. 13-611V
Petitioners,	*	Special Master Gowen
v.	*	Entitlement Decision; Diphtheria-Tetanus-acellular Pertussis (DTaP) Vaccine; Inactivated Polio Vaccine (IPV); Haemophilus Influenzae (HiB) Vaccine; Pneumococcal Conjugate (PCV) Vaccine; Rotavirus Vaccine; Sudden Infant Death Syndrome (SIDS).
SECRETARY OF HEALTH AND HUMAN SERVICES,	*	
Respondent.	*	

Ronald C. Homer & Joseph M. Pepper, Conway, Homer P.C., Boston, MA, for petitioners. Lara A. Englund & Ryan M. Pyles, United States Department of Justice, Washington, DC, for respondent.[1]

RULING ON ENTITLEMENT[2]

On August 27, 2013, Chase Boatmon and Maurina Cupid ("petitioners"), as the representatives of the estate of their deceased minor child, J.B., filed a petition under the National Vaccine Injury Compensation Program ("Vaccine Act" or the "Program"),[3] 42 U.S.C. § 300aa-10 *et. seq.* (2012). Petitioners allege that as a result of receiving vaccinations for

[1] Mr. Homer is petitioners' attorney of record, while his colleague Mr. Pepper appeared at the entitlement hearing. Similarly, for respondent, Ms. Englund has always been the attorney of record, but Mr. Pyles appeared at the entitlement hearing.

[2] Because this decision contains a reasoned explanation for the action in this case, the undersigned intends to post it on the website of the United States Court of Federal Claims, pursuant to the E-Government Act of 2002, *see* 44 U.S.C. § 3501 note (2012). The court's website is at http://www.uscfc.uscourts.gov/aggregator/sources/7. Before the decision is posted on the court's website, each party has 14 days to file a motion requesting redaction "of any information furnished by that party: (1) that is a trade secret or commercial or financial in substance and is privileged or confidential; or (2) that includes medical files or similar files, the disclosure of which would constitute a clearly unwarranted invasion of privacy." Vaccine Rule 18(b). "An objecting party must provide the court with a proposed redacted version of the decision." *Id.* If neither party files a motion for redaction within 14 days, the decision will be posted on the court's website. *Id.*

[3] The National Vaccine Injury Compensation Program is set forth in Part 2 of the National Childhood Vaccine Injury Act of 1986, Pub. L. No. 99-660, 100 Stat. 3705, codified as amended, 42 U.S.C. §§ 300aa-1 to -34 (2012). All citations in this decision to individual sections of the Vaccine Act are to 42 U.S.C. § 300aa.

Diphtheria-Tetanus-acellular Pertussis ("DTaP"), inactivated polio ("IPV"), haemophilus influenzae ("HiB"), Pneumococcal Conjugate ("PCV"), and Rotavirus vaccinations on September 2, 2011, J.B. passed away from Sudden Infant Death Syndrome ("SIDS") on September 3, 2011. *See* Petition (ECF No. 1); Amended Petition (ECF No. 15).

After carefully analyzing and weighing all of the evidence and testimony presented in this case in accordance with the applicable legal standards, the undersigned finds that petitioners have met their legal burden. Petitioners have put forth preponderant evidence that the vaccines J.B. received on September 2, 2011 actually caused or substantially contributed to his death from Sudden Infant Death Syndrome. Furthermore, respondent has failed to put forth preponderant evidence that J.B.'s death was in fact caused by factors unrelated to the vaccines. Accordingly, petitioners are entitled to compensation.

I. BACKGROUND

A. Procedural History

Petitioners filed a petition for compensation pursuant to the Vaccine Act on behalf of their deceased minor son, J.B., on August 27, 2013. Petition (ECF No. 1). They filed an amended petition on February 6, 2014. Amended Petition (ECF No. 15). Petitioners filed the expert report of Dr. Douglas C. Miller, a neuropathologist, along with the medical literature referenced in his report, on May 20, 2014. Exhibit 13, 14 (ECF No. 21).[4]

On September 9, 2014, respondent filed a Rule 4(c) report advising against compensation. Rule 4(c) Report (ECF No. 28). That same day, he filed an expert report and medical literature referenced therein from Dr. Brent Harris, a pathologist. Exhibit A (ECF No. 29). Respondent also filed an expert report and medical literature from Dr. Christine T. McCusker. Exhibit C (ECF Nos. 30-32). Petitioners filed a supplemental report from Dr. Miller on November 10, 2014. Exhibit 16 (ECF No. 35). Extensive and detailed medical literature was submitted in support of all of the expert reports.[5]

At numerous stages of this case, the undersigned encouraged the parties to pursue the possibility of an informal resolution and/or to consider mediation. *See, e.g.*, Order filed December 9, 2014 (ECF No. 37). The parties ultimately did not settle the case. An entitlement hearing was held on Thursday, August 6, and Friday, August 7, 2015, in Washington, D.C. Dr. Miller testified on behalf of petitioners, and Dr. Harris and Dr. McCusker testified for respondent. The case was well tried and involved detailed expert testimony from both sides. *See*

[4] On October 14, 2014, petitioners refiled the medical literature cited in Dr. Miller's report, highlighting the specific portions being relied upon to support causation. Petitioners' Notice of Refiling Documents (ECF No. 34).

[5] I have read and digested all of the literature submitted in this case and will reference numerous but not all articles in the course of this opinion. However, all articles have been considered in coming to a conclusion in this case. More recent articles, particularly those by the same authors or groups, are referenced more frequently because they incorporate, build upon, and update the earlier literature. Petitioners and Dr. Miller filed Exhibits 13-A through 13-V and Exhibits 14 through 21. Respondent and Dr. Harris filed Exhibits A-1 through A-6. Respondent and Dr. McCusker submitted Exhibits C-1 through C-20 and Exhibits D through G.

Transcript filed on September 9, 2015 (ECF Nos. 50, 52). Petitioners filed their post-hearing brief on December 7, 2015. (ECF No. 61). Respondent filed his post-hearing brief on March 7, 2016. (ECF No. 63). Petitioners filed their reply to respondent's post-hearing brief on March 28, 2016. (ECF No. 64). This matter is now ripe for adjudication.

B. Standards for Adjudication

The Vaccine Act established the Program to compensate vaccine-related injuries and deaths. § 300aa-10(a). "Congress designed the Vaccine Program to supplement the state law civil tort system as a simple, fair and expeditious means for compensating vaccine-related injured persons. The Program was established to award 'vaccine-injured persons quickly, easily, and with certainty and generosity.'" *Rooks v. Sec'y of Health & Human Servs.*, 35 Fed. Cl. 1, 7 (1996) (quoting H.R. Rep. No. 908 at 3, reprinted in 1986 U.S.C.C.A.N. at 6287, 6344).

There are two avenues to compensation under the Program. The first is to demonstrate a "Table injury," that is, a specified injury within a specified period of time following administration of a vaccine listed on the Vaccine Injury Table. § 300aa-14(a). A Table injury creates a presumption of causation, which is only defeated if respondent shows that the injury was caused by a factor or factors unrelated to the vaccine. In the present case, petitioners allege that J.B. died suddenly of a cause that remained unexplained after a site investigation and autopsy, often referred to as SIDS, shortly after receiving various vaccines listed on the Table. The Table does not list SIDS occurring in any period of time after any vaccine.

Therefore, petitioners must take the second avenue towards compensation: they must establish an "off-Table injury," meaning that the vaccine(s) were the cause in fact of the vaccinee's injuries. In *Althen*, the Federal Circuit established a three-prong test: petitioners must establish (1) a medical theory causally connecting the vaccination and the injury; (2) a logical sequence of cause and effect showing that the vaccination was the reason for the injury; and (3) a proximate temporal relationship between vaccination and injury. *Althen v. Sec'y of Health & Human Servs.*, 418 F.3d 1274, 1278 (Fed. Cir. 2005).

The legal standard is by a preponderance of the evidence." §300aa-13(a)(1)(a). This does not require "conclusive scientific evidence" or "certainty." *Moberly v. Sec'y of Health & Human Servs.*, 592 F.3d 1315, 1322 (Fed. Cir. 2010). Instead, the standard has been interpreted to mean that a fact is more likely than not. *Id.* at 1322 n.2. The Federal Circuit has observed that this preponderance standard enables "the finding of causation in a field bereft of complete and direct proof of how the vaccines affect the human body." *Althen*, 418 F.3d at 1280. Petitioners must establish each *Althen* prong by the preponderance of the evidence. *Caves v. Sec'y of Health & Human Servs.,* 100 Fed. Cl. 119, 132 (2011), *aff. per curiam*, 463 Fed. Appx. 932 (Fed. Cir. 2012).

Each *Althen* prong may be satisfied by medical records or a medical opinion. *Althen*, 418 F.3d at 1279; *see also Capizzano v. Sec'y of Health & Human Servs.*, 440 F.3d 1317, 1326 (Fed. Cir. 2006) (noting that the same piece of evidence can support several *Althen* prongs). Petitioners are not required to provide "objective confirmation" by way of "medical

documentation." *Id.* at 1278. Such a requirement would "contravene the plain language of the statute." *Id.* at 1281.

In determining whether a petitioner is entitled to compensation, a special master must consider the entire record and is not bound by any particular piece of evidence. § 13(b)(1) (stating that a special master is not bound by any "diagnosis, conclusion, judgment, test result, report, or summary" contained in the record). Thus, a special master must weigh and evaluate opposing expert opinions, medical and scientific evidence, and the evidentiary record in deciding whether petitioners have met their burden of proof.

Epidemiological studies, or the lack thereof, are not dispositive of the causation in fact determination. *Grant v. Sec'y of Health & Human Servs.*, 956 F.2d 1144, 1149 (Fed. Cir. 1992). Indeed, petitioners are not required to present medical literature or epidemiological evidence to establish any *Althen* prong. *Andreu v. Sec'y of Health & Human Servs.*, 569 F.3d 1367, 1380 (Fed. Cir. 2009). However, the special master can consider [epidemiological evidence] in reaching an informed judgment as to whether a particular vaccination likely caused a particular injury…. Medical literature and epidemiological evidence must be viewed… not through the lens of the laboratorian, but instead from the vantage point of the Vaccine Act's preponderant evidence standard." *Andreu*, 569 F.3d at 1380.

Under the second *Althen* prong, petitioners need to show that the vaccine(s) was "not only a but-for cause of the injury but also a substantial factor in bringing about the injury." *Shyface v. Sec'y of Health & Human Servs.*, 165 F.3d 1344, 1352-53 (Fed. Cir. 1999). They do not need to show that the vaccine(s) was the "sole" or even the "predominant" cause. *Id.* at 1352. For example, in *Shyface*, the Federal Circuit affirmed that petitioners were entitled to compensation, based on their expert's testimony that the vaccine together with a bacterial infection caused the child's high fever and death (although the expert could not testify that the vaccine was the "sole" or "predominant" cause. 165 F.3d at 1353.

Showing a logical sequence of cause and effect between the vaccine(s) and the injury will tend to show that the injury was not caused by an alternative cause. However, a petitioner is not required to eliminate all possible alternative causes of the injury. *See Walter v. Sec'y of Health & Human Servs.*, 485 F.3d 1146, 1150 (Fed. Cir. 2007) ("the Vaccine Act does not require the petitioner to bear the burden of eliminating alternative causes where the other evidence on causation is sufficient to establish a *prima facie* case"). This standard permits the use of "circumstantial evidence" and accomplishes Congress's goal that "close calls regarding causation are resolved in favor of injured claimants." *Althen*, 165 F.3d at 1280.

Once a petitioner fulfills the *Althen* test, the burden of persuasion shifts to respondent to show that the alleged injury was caused by a factor unrelated to the vaccination. *Knudsen*, 35 F.3d 543 at 548; § 13(a)(1)(B). Respondent has the burden of demonstrating that "a factor unrelated to the vaccination is the more likely or principal cause of the injury alleged. Such a showing establishes that the factor unrelated, not the vaccination, was 'principally responsible' for the injury." *Deribeaux v. Sec'y of Health & Human Servs.,* 717 F.3d 1363, 1369 (Fed. Cir. 2013). Section 13(a)(2) specifies that factors unrelated "[do]not include any idiopathic, unexplained, unknown, hypothetical, or undocumented causal factor, injury, illness, or

condition." Close calls regarding causation must be resolved in favor of the petitioner. *Althen*, 418 F.3d at 1280; *Knudsen*, 35 F.3d at 551 ("If the evidence (on alternative cause) is seen in equipoise, then the government has failed in its burden of persuasion and compensation must be awarded.

C. Summary of Relevant Facts

J.B. was born on April 7, 2011, when his mother became pre-eclamptic and underwent a Caesarean section. Exhibit 1 at 10. J.B. was born 4 weeks prematurely at 36 weeks gestation. Exhibit 2 at 3. The mother's medical records report no history of tobacco, alcohol, or illicit drugs. Exhibit 1 at 3. At birth, J.B. was noted to be "well appearing, non-dysmorphic[,] alert and in no acute distress." Exhibit 2 at 9. His Apgar scores[6] were 8 at 1 minute and 9 at 5 minutes. Exhibit 2 at 9. J.B. and his mother are both noted to be African-American. Exhibit 2 at 3, 25.

On April 14, 2011, one week after birth, J.B. received his first Hep B vaccination. Exhibit 2 at 82.[7] At his two-week well baby visit on April 21, 2011, J.B. was "well appearing, alert . . . a healthy appearing 2 [week] old with normal growth and development." *Id.* at 79-81. On June 7, 2011, J.B. – exhibiting a cough and a runny nose – was brought to the emergency room. *Id.* at 73. He underwent a chest x-ray that revealed "no radiographic evidence of acute cardiopulmonary disease." *Id.*

J.B.'s subsequent well-baby visits were scheduled to account for the fact of his being born 4 weeks prematurely. On July 22, 2011, more than three months after J.B.'s birth, he had a two-month well baby visit with his pediatrician, Laura Wright, M.D. Exhibit 3 at 8-10. Dr. Wright's evaluation was thorough and well documented. *Id.* J.B. had no feeding difficulties, slept best at night, slept in his own room, and slept on his back. *Id.* at 8. He was noted to be a "well child, almost 4 months but behind on [vaccinations]" with "normal growth and development." *Id.* at 10. J.B. received DTaP, IPV, PCV, rotavirus, and Hep B vaccinations at this visit. *Id.* at 2, 8.

On September 2, 2011, almost five months after J.B.'s birth, he had his four-month well baby visit with Dr. Wright. Exhibit 3 at 5-7. He was nearly five months post-delivery, although his gestational age was about four months given his early delivery. J.B. was sleeping up to seven hours at a time, on his back, in a crib in his own room. *Id.* at 5. He was described as "healthy appearing and cooperative . . . well-nourished and well developed." *Id.* His chest and lungs were normal with no adventitious[8] sounds. *Id.* at 6.

---

[6] Apgar score is defined as "a numerical expression of the condition of a newborn infant, usually determined at 60 seconds after birth, being the sum of points gained on assessment of the heart rate, respiratory effort, muscle tone, reflex irritability, and color." *Dorland's Illustrated Medical Dictionary* (32d ed. 2012) ("*Dorland's*") at 1682.

[7] Petitioners' expert, Dr. Miller, stated that normally an infant receives the first Hep B vaccination a day after delivery or just before going home. Exhibit 13 at 3. Dr. Miller characterized J.B. receiving the first Hep B vaccination one week after delivery as "a little unusual [but…] likely inconsequential." *Id.*

[8] Adventitious is defined as "accidental or acquired; not natural or hereditary." *Dorland's* at 34.

J.B.'s heart rate was regular with normal heart sounds and no pericardial friction rubs. *Id.* His reflexes were all 2/2 and his red reflex was normal. *Id.* His weight was 16 pounds, 8 ounces. *Id.* at 5. For infants of his age, his weight was stable at the 50th percentile, his height was up at the 50th percentile, and his head circumference was at the 75th percentile. *Id.* Nasal mucosa was normal, turbinates[9] were normal, and nares[10] were patent. Oropharynx was normal. *Id.* at 6. He was recorded as not having a fever, nasal congestion, or cough and history of wheezing. *Id.* at 5. He met numerous 4-month developmental milestones, including "head up 45 degrees, head up 90 degrees, sits – head steady." *Id.* During this visit, J.B. received DTaP, IPV, PCV, rotavirus, and Hep B vaccinations. *Id.* at 6; Exhibit 4 at 1. Dr. Wright completed her records from this visit on September 2, 2011, at 10:45 a.m., suggesting that the appointment had concluded by that time. Exhibit 3 at 7.

J.B.'s father attested that during the well-baby visit, J.B. was "smiling and cooing like normal." Exhibit 11 at 1. However, later that day after J.B. received the vaccinations, he "was not laughing or cooing like he normally did[,] he was not moving as much[, and] he seemed quiet and withdrawn." *Id.* That night, J.B. had a fever and he did not sleep well. *Id.* [11]

J.B.'s mother and father stated that on September 3, 2011, at 4:00 a.m., they gave J.B. Advil,[12] after which he went to bed in a supine position (on his back). Exhibit 8 at 2. When J.B. woke up a few hours later, he was distant, very quiet, and would not eat. Exhibit 11 at 2. He began running a fever again and was given another dose of Advil at approximately 8:00 a.m. *Id.*;

---

[9] Turbinate is defined as "any of the nasal conchae.*" *Dorland's* at 1991.

[10] Nares is defined as "the external orifices of the nose; [also known as] nostrils." *Dorland's* at 1232.

[11] The following factual summary draws from:

- Exhibit 5 – Suffolk, Virginia Department of Fire & Rescue records of responding to the home on September 2, 2011.
- Exhibit 7 – Suffolk, Virginia Police Department records. This includes notes from the police's response to the home on September 3, 2011, and the police department's formal report on their response and a handwritten statement from J.B.'s mother, both completed on September 8, 2011.
- Exhibit 8 – Office of the Chief Medical Examiner, Tidewater District, Norfolk, Virginia, Records. This exhibit contains a summary of a child death reenactment with a doll, performed with J.B.'s parents in their home on September 8, 2011. Exhibit 8 at 3. The autopsy report was completed on November 2, 2011. Exhibit 8 at 1-2; 4-9.
- Exhibit 9 – Suffolk, Virginia Police Department records – photos of a bottle of Advil, taken on September 8, 2011; J.B. following the autopsy, undated; and the crib, bedroom, and exterior of the home, taken on September 3, 2011.

J.B.'s mother and father were not present to testify at the entitlement hearing.

[12] A bottle of children's Advil was taken into evidence. Exhibit 7 at 47. *But see* Exhibit 6 at 2, 5 ("aspirin"); Exhibit 8 at 2 ("infant Tylenol"); Exhibit 8 at 4-6 ("over-the-counter acetaminophen"). To the extent that it makes any difference it would seem most likely that it was the Advil that was given and the other notations were made subsequently without that same attention to this detail that the site investigation utilized.

Exhibit 7 at 11. J.B.'s mother said that J.B. sat up and played with her nephews during the morning. Exhibit 7 at 16.

In the early afternoon, J.B. became fussy and his father put him down for a nap in his bedroom, on the second floor of the house. Exhibit 7 at 3, 16; Exhibit 8 at 2. His father attested that he placed J.B. supine with his head to the right. Exhibit 7 at 5; Exhibit 8 at 3. J.B. seems to have had a pacifier in his mouth. Exhibit 7 at 16. He was placed in the middle of his crib, with a blanket across his midsection. Exhibit 8 at 3. The crib also contained a "little crib pillow – very flat," but no clutter or toys. Exhibit 7 at 5; Exhibit 8 at 3. J.B.'s mother attested that the air conditioning was always set at 76 degrees Fahrenheit. Exhibit 7 at 4. She indicated that J.B. slept on his back and that he could roll over on his own, lift his head, and pull or push himself up. Exhibit 7 at 5.

After putting J.B. down for his nap, his father left the home to get lunch. Exhibit 11 at 2. His mother remained in the home, but "heard [J.B.] fussing in crib" while she was cleaning and on the phone. Exhibit 7 at 16. After some period of time, J.B.'s mother went upstairs and put the pacifier in J.B.'s mouth. *Id.* (noting that J.B. "tend[ed] to cry when he spit the pacifier out"). When she returned, she found J.B. on his right side, with his head turned slightly, and unresponsive. Exhibit 7 at 17; Exhibit 8 at 2-3. She called J.B.'s father and said that J.B. was not breathing. Exhibit 7 at 17; Exhibit 11 at 2. The father told her to call 911 and he headed home. Exhibit 11 at 2.

J.B.'s mother said that "approximately 50 minutes passed" between his father placing J.B. down for a nap and when she found J.B. unresponsive. Exhibit 8 at 2. There was a "10-minute window" between when his mother checked on J.B. and replaced his pacifier, and when she returned to find him unresponsive. Exhibit 5 at 2. She informed the police that his nose and mouth were not covered. Pet. Ex 7 p 5.

J.B.'s mother called 911 at 2:39 p.m. Exhibit 7 at 35. She then attempted CPR. Exhibit 5 at 2; Exhibit 7 at 17. It appears that she removed him from the crib and placed him on his back on the floor. Exhibit 7 at 9-10. Officer Anderson was the first to arrive, at 2:42 p.m. – just 3 minutes and 21 seconds after the call. Exhibit 7 at 7, 9, 11, 35. Upon entering the home and going upstairs, the officer found J.B. lying on the bedroom floor, perpendicular to his crib. *Id.* at 9. J.B. was face up, with his eyes closed, and unresponsive. *Id.* He was still warm, but had no pulse or breath. *Id.* J.B.'s mother was kneeling over him. *Id.* The officer performed chest compressions until EMS arrived. *Id.*

The first responders left with J.B. at 3:02 p.m. and arrived at the emergency department of Harborview Medical Center at 3:08 p.m. Exhibit 7 at 36. J.B. was given oxygen under pressure during transport, but PEA (pulseless electrical activity) was noted on the monitor. Exhibit 5 at 1-2. Efforts at resuscitation were unsuccessful and J.B. was pronounced dead at the hospital, on September 3, 2011, at 4:01 p.m. Exhibit 7 at 10.

On September 5, 2011, a medical examiner, Dr. Jeffrey Gofton, completed an autopsy report for J.B. Exhibit 8 at 4-6. The medical examiner noted that the scene reenactment indicated that J.B. was placed to sleep on his back and was later found on his right side. *Id.* at 6. Scene photographs indicated a crib with soft blankets and a flat soft pillow, but no clutter or toys in the bed. *Id.* It was further noted that J.B. had no known medical problems, with regular infant care and immunizations. *Id.* He had a well-baby check-up on the day prior to his death, during which he received multiple vaccinations. *Id.* He had reportedly been fussy and had an intermittent temperature that seemed to be controlled with Tylenol. *Id.* J.B. was reportedly placed to sleep on his back and later found on his right side. *Id.* The medical examiner stated that J.B.'s lungs exhibited congestion and pulmonary edema.[13] *Id.* However, J.B. had no traumatic injury, congenital abnormalities, or viruses such as influenza. *Id.* Both a cerebral spinal fluid culture and a nasopharyngeal swab for viruses were negative. *Id.* J.B.'s brain weighed 876 grams (normal is 620 plus or minus 71 grams). *Id.* There was no evidence of epidural, subdural, or subarachnoid hemorrhage. *Id.* Serial sectioning showed normal configuration and infantile myelination of the cerebrum. *Id.* The brainstem was normally formed with no focal lesions. *Id.* at 5. Extensive drug testing was performed and was negative. *Id* at 6. The medical examiner, based on the "absence of findings and the reported sleeping position in a child with no anatomic or microscopic significant findings," stated that "the cause of death was SIDS and the manner was "natural." *Id.* The parties agree that the characterization of J.B.'s cause of death as SIDS is appropriate. Joint Prehearing Submission at 2.

The parties' experts in neuropathology – Dr. Miller for petitioners and Dr. Harris for respondent – reviewed 21 slides from J.B.'s autopsy, including two of J.B.'s brain. Exhibit 13 at 4-5; Exhibit A at 5. The first brain slide is a cross-section of pons at the level of the locus coeruleus (the upper pons), and the second slide is of two cingulate gyri with a portion of the adjacent corpus callosum. Exhibit 13 at 5. These brain sections demonstrated no abnormalities. *Id.* However, the medical examiner did not make slides from other parts of the brain, such as the medulla or hippocampus. *Id.* Furthermore, he did not take any photographs of the internal examination. *Id.* The parties' experts agreed that the medical examiner did not collect all of the data necessary to definitively analyze whether J.B. fit the Triple Risk Model of SIDS, introduced in the following section. Tr. 42-43 (testimony of Dr. Miller); Tr. 334 (testimony of Dr. Harris). The experts agreed that they would section considerably more of the brain in a possible SIDS autopsy than the two frontal lobes and one area of the pons that were sectioned in this case. Dr. Harris indicated that usually a SIDS autopsy should include samples of at least ten areas, including the medulla and hippocampus, which can help to show hypoxic ischemic changes as well as epilepsy related changes. Tr. 334. Both experts agreed, however, that in many SIDS cases, brains are not examined with the precision that they would recommend or that Dr. Kinney's group at Harvard did in their studies (introduced in the following section). Tr. 346.

[13] Dr. Miller and Dr. Harris agreed that congestion in the brain and lungs and other organs is a very common and non-specific finding at autopsy from which they would not draw any conclusion. Tr. 103 (Miller); Tr. 332-33 (Harris).

II. SUMMARY OF THE EVIDENCE

A. Medical Literature

The parties submitted voluminous literature to explain what is understood about sudden infant death syndrome ("SIDS"), the potential role of inflammatory cytokines generated by vaccines in acting as a necessary trigger, and the epidemiology of SIDS. Both parties submitted various studies from Hannah C. Kinney, M.D., a neuropathologist at Harvard, and others on her team which leads the research and current understanding of SIDS. The later articles tend to build upon and incorporate the earlier articles. Studies by other authors on SIDS and related subjects served to supplement and generally confirm that by Kinney et al.

A review of the literature is critical to the determination of whether petitioners have satisfied the *Althen* prongs (a reliable theory of how vaccines *can* cause death from SIDS, that the vaccines did in J.B.'s particular case, and that there was a medically acceptable temporal relationship between the vaccinations and J.B.'s death). This review is also necessary to determine whether respondent has sufficiently rebutted petitioners' theory by demonstrating that J.B.'s death was caused by factors unrelated to the vaccine.

SIDS is defined as "the sudden death of an infant under one year of age which remains unexplained after a thorough case investigation, including performance of a complete autopsy, death scene investigation, and review of the clinical history."[14] "Epidemiological studies link SIDS with sleep periods, leading to the premise that SIDS occurs during sleep or transitions between sleep and waking." *Id.*

SIDS is the leading cause of infant mortality in the United States, with an incidence of 0.53 per 1,000 infants.[15] Research has revealed that infants put to sleep in the prone position, i.e., with their heads facing downward, are twice as likely to experience SIDS. *Id.* Other risk factors for SIDS related to the "sleeping environment" have been recognized, including "[being] found face-down, head covered, sleeping on an adult mattress, couch or playpen, soft bedding, [and] bed-sharing." *Id.*

In 1994, Dr. Hannah C. Kinney, Dr. James Filiano, and their colleagues synthesized many neuropathological studies into their proposed Triple Risk Model.[16] This model posits that SIDS occurs when: (1) an infant in a critical development period; (2) possessing an underlying vulnerability; (3) encounters an exogenous stressor. *Id.* The following Venn diagram has been used to illustrate the Triple Risk Model:

---

[14] Filiano, J.J. & H.C. Kinney, *Arcuate Nucleus Hypoplasia in the Sudden Infant Death Syndrome*, 51 J. Neuropathol. Exp. Neurol. 394 (1992), Exhibit 13-A at 394.

[15] Trachtenberg F.L., E.A. Haas, H.C. Kinney, C. Stanley & H.F. Krous, *Risk Factor Changes for Sudden Infant Death Syndrome After Initiation of Back-to-Sleep Campaign*, 129 Pediatrics 630 (2012), Exhibit C-11 at 631.

[16] Filiano, J.J. & H.C. Kinney, *A Perspective on Neuropathologic Findings in Victims of the Sudden Infant Death Syndrome*, 65 Biol. Neonate 194 (1994), Exhibit 13-B at 195 [also filed as Exhibit A-2].

Id. at 3, Figure 1. This model emphasizes the intersection of multiple factors in the pathogenesis of SIDS. According to this model, SIDS occurs only when components of all three factors are present simultaneously, which explains why all infants who are placed prone to sleep or who bed share do not die of SIDS.[17]

1. First Risk Factor: Critical Development Period

The first factor in the Triple Risk Model of SIDS is the critical development period, which Kinney et al. initially defined as the first year of life.[18] However, their more recent literature tends to define it as the first six months of life.[19] The peak incidence of SIDS deaths has historically occurred between two and four months of age. A study by Trachtenberg, Kinney, and others published in 2012 found slightly more younger and older infants succumbing to SIDS than had been seen in earlier studies. In the groups studied, the percentage of SIDS babies who were five months or more rose from 11.8% in the pre-Back-to-Sleep[20] era, to 17.6% in the 1996-2008 post-Back-to-Sleep era.[21] Kinney and Thach wrote, "Given the wide array of homeostatic functions modulated by the medullary 5-hydroxytrptamine system, sudden death may result from a convergence of defects in protective response to homeostatic stressors during sleep that are modulated by 5-hydroxytrptamine, probably in conjunction with related neurotransmitters."[22]

---

[17] Kinney, H.C. et al., *The Brainstem and Serotonin in the Sudden Infant Death Syndrome*, 4 Annu. Rev. Pathol. Mech. Dis. 517 (2009), Exhibit 13-H at 521.

[18] Filiano & Kinney (1992), Exhibit 13-A at 394.

[19] *See, e.g.*, Kinney et al. (2009), Exhibit 13-H at 521.

[20] The "Back to Sleep" campaign refers to a major public health effort to encourage parents to place their infants on their backs to sleep, particularly during the first year of life as a means of reducing the incidence of SIDS.

[21] Trachtenberg, Kinney, et al. (2012), Exhibit C-11 at 634.

[22] Kinney, H.C. & B. Thach, *The Sudden Infant Death Syndrome*, 361 New England J. of Med. 795 (2009), Exhibit A-4 at 6.

2. Second Risk Factor: Vulnerable Infant

After Kinney et al. formulated the Triple Risk Model, the initial research was focused on determining why particular infants were "vulnerable", possibly because of environmental or genetic factors. Exhibit 13-H at 5. Intrinsic risk factors include "male gender, African-American race, poverty, adverse prenatal factors such as maternal smoking or alcohol use during pregnancy, and genetic polymorphisms." *Id.* It was also hypothesized as early as 1987 that most likely SIDS was related to a brainstem abnormality in the neuroregulation of cardiorespiratory control.[23] These intrinsic factors when combined with the vulnerable developmental period of the infant and a critical exogenous factor resulted in sudden infant death. As research progressed over the following decades, the above intrinsic risk factors remained but a significant emphasis was placed on the brainstem hypothesis, based upon the research of Dr. Kinney and others. In 2009, Dr. Kinney explained: "To date the most robust evidence for a neurochemical abnormality comes from research on the medullary 5-HT system,[24] in that approximately 50-70% of infants with SIDS appear to have abnormalities in this system. The medullary 5-HT system, which is considered critical for the modulation and integration of diverse homeostatic functions, is involved in ventilation and gasping, thermoregulation, autonomic control, response to carbon dioxide and oxygen, arousal from sleep, and hypoxia-induced plasticity.[25]

The 5-HT system refers to the serotonin system. "The caudal serotonergic (5-HT) system is a critical component of a medullary "homeostatic network" that regulates protective response to metabolic stressors such as hypoxia, hypercapnia and hyperthermia."[26] "Homeostasis refers to the ability of an organism to maintain a constant internal environment, thereby allowing survival over a wide range of external environmental conditions. It becomes self-sufficient at the moment of birth as the fetus takes the first breath in the extra-uterine world and begins to adjust instantaneously and independently to the myriad of changing metabolic demands. ... Receptor systems that sense deviations in any internal milieu (e.g., oxygen and carbon dioxide, glucose, and temperature levels) have been defined as well as the effector systems that are the final common pathway in mediating adjustments. Major focus has been placed upon the brain as the 'control center' which sets the range at which a particular parameter namely CO2 is maintained, and determines the protective response to deviations from this range namely hypercarbia."[27,28]

---

[23] Kinney et al. (2009), Exhibit 13-H at 519.

[24] 5-HT (5-hydroxytryptamine), also called serotonin, is defined as "a monoamine vasoconstrictor, synthesized in the intestinal chromaffin cells or in central or peripheral neurons and found in high concentrations in many body tissues, including the intestinal mucosa, pineal body, and central nervous system." *Dorland's* at 1699.

[25] Kinney & Thach (2009), Exhibit A-4 at 6.

[26] Kinney, H.C. et al., *The Serotonergic Anatomy of the Developing Human Medulla Oblongata: Implications for Pediatric Disorders of Homeostasis*, 41 J. Chem. Neuroanat. 12 (2011), Exhibit 13-F at 182.

[27] Hypercarbia, also called hypercapnia, is defined as "excess of carbon dioxide in the blood." *Dorland's* at 887.

[28] Kinney et al. (2009), Exhibit 13-F at 183.

The serotonergic system, primarily concentrated in the medulla oblongata, which is called the caudal 5-HT system or the medullary 5-HT system, is now recognized as a key component of the brain's control system of homeostasis. *Id.* Dr. Kinney proposed that deficits in the caudal 5-HT system will lead to imbalances in respiratory, cardiovascular, and/or metabolic regulation – including in response to stress – in the pediatric age range, particularly in the first days and months following birth. *Id.* As noted by the Kinney group in a 2011 article on the serotonergic anatomy, "extensive experimental data implicate the caudal 5-HT system in homeostasis and respiratory and autonomic regulation, including upper airway control, respiration (including via modulation of the pre-Botzinger complex, the putative central rhythm generator of respiration), autoresuscitation, central chemoreceptor responses to hypercapnia and hypoxia, cardiovascular control, pain, motor function, and thermoregulation." *Id.* The article also notes that the medullary 5-HT system "interfaces with the cytokine system which is critical to homeostasis in its mediation of 'protective sickness' behaviors and cellular defenses against tissue damage." *Id.*

Dr. Kinney's team's research on the brainstem focused on a collection of neurons in the ventral medullary surface known as the arcuate nucleus "based upon cytological and positional homologies between the respiratory chemosensitive fields on the ventral medullary surface in cats. Structural underdevelopment of the arcuate nucleus was subsequently observed in SIDS cases."[29] As the research advanced, it was recognized that the "arcuate anomaly was similar to that reported in infants with clinical insensitivity to CO2 and sleep related sudden death." *Id.* By 2009, Dr. Kinney reported, "*Serotonergic neurons at the medullary ventral surface and in the midline (raphe) are now known to be preferentially chemosensitive to CO2* and although they are not the only central chemosensitive neurons they appear to play a critical potentially modulatory role…A small but important population of 5-HT neurons is embedded within the human arcuate nucleus suggesting that the putative dysfunction in chemosensitivity related to the arcuate anomaly specifically involved these embedded 5-HT neurons." *Id.* (emphasis added).

"Serotonergic neurons are well-suited to a role as central respiratory chemo-receptors, as they are closely associated with the basilar artery and its largest branches near the ventral surface of the medulla namely they are in a position to directly monitor arterial PCO_2.... 5-HT neurons respond intrinsically to increased PCO_2[30] with large increases in firing rate; this response is due to a decrease in intracellular pH induced by hypercapnia. On average these neurons increase their firing rate threefold in response to a decrease in pH of 7.4 to 7.2. Chemosensitivity increases during postnatal development, with a blunted response to pH before postnatal date 12 in rats. Physiological delay in chemosensitivity is potentially relevant to SIDS because it indicates that 5-HT neurons may be immature during the critical developmental period, throughout which all infants are susceptible to hypercapnia."[31] Harper and Kinney state the data now suggest that SIDS is associated with a brainstem (medullary) 5-HT deficiency rather than 5-

[29] Kinney et al. (2009), Exhibit 13-H at 522. Kinney defines chemosensitivity as "the ventilator response to a change in carbon dioxide/pH as sensed by tissue chemoreceptors, which are composed of neurons and/or astrocytes." *Id.*

[30] PCO_2 is defined as "the partial pressure of carbon dioxide." *Dorland's* at 2120.

[31] Kinney et al. (2009), Exhibit 13-H at 530.

HT overproduction.[32] Of note, the medullary 5-HT profile differed between infants dying of SIDS and those dying with known chronic oxygenation disorders, suggesting that chronic hypoxia does not necessarily play a major role in the pathogenesis of the impairments in the 5-HT tissue markers. *Id.*

Harper & Kinney explained that the insufficient function of the 5-HT system, which is necessary for breathing, leaves an infant vulnerable to a variety of crisis situations. These include external airway obstruction, upper airway obstruction resulting from loss of tone in the upper airway musculature in association with diaphragmatic movements, or importantly of central apnea, which has occupied a central focus of attention. These are also proposed mechanisms underlying the fatal event in SIDS. This failure can result from several components of the breathing process, including impaired sensory transduction or integration of either carbon dioxide or oxygen, or non-recruitment of gasping mechanisms, the final restorative mechanism to low oxygen. In SIDS, a principal concern is the "loss of the wakefulness drive to breathe." *Id.* at 5. The waking state activates processes which maintain breathing, while during sleep those influences are suppressed or not recruited. Thus, impaired central chemosensitivity to excess carbon dioxide or inadequate oxygen contributed to by defects in the medullary serotonin system, in addition to the normal reduction of the function of the 5-HT system during sleep, may play a central role in SIDS, which occurs primarily during sleep. *Id.* at 4-5.

Despite the emphasis on brainstem abnormality or underdevelopment, the other intrinsic risk factors are thought to continue to play an important role in the multi-factorial analysis of SIDS causation. Some of these factors may be related to the medullary 5-HT deficits described above. Several intrinsic risk factors are apparent in J.B.'s case. First, prematurity is defined as less than 37 weeks at birth[33] and J.B. was born at 36 weeks. Male gender, as boys exceed girls in SIDS deaths by a two-to-one ratio, and African-American race have also been called intrinsic risk factors because they are over-represented among SIDS victims.[34] Importantly, maternal smoking and alcohol consumption during pregnancy are considered important risk factors but are not relevant in this case, as J.B.'s mother did not smoke or drink during or after her pregnancy.

Dr. Kinney has hypothesized that males may predominate among SIDS deaths because males tend to be less responsive to the accumulation of carbon dioxide, and in the situation with a defective medullary 5-HT system may be particularly impaired from responding to excess carbon dioxide during sleep. *Id. T*he predominance of males in the occurrence of SIDS appears to be potentially related to the reduction of 5-HT binding in the medullary raphe compared to females dying of SIDS, as well as the report that plasma levels of testosterone, but not estradiol, are significantly higher in both male and female SIDS infants compared to age-matched controls. Several studies in knockout mice and piglets also "underscore gender differences in brainstem-mediated 5-HT function, with females' brains apparently relying less on 5-HT neurons in chemoreception and adapting more readily to the loss of 5-HT function. *Id.*

[34] Kinney et al. (2009), Exhibit 13-H at 532.

The role of African-American race in SIDS is less defined, other than statistically. Most authors speculate that the statistical predominance of African-American children may represent lower socioeconomic status resulting in inadequate medical care. If that be the case however, J.B.'s race should not be an increased risk factor as he was receiving regular medical care with comprehensive and well-documented well baby visits occurring in July and September. His first set of vaccinations was somewhat late, but the second dose, those received on September 2, 2011, brought him up to date. His growth and functional milestones appeared to be normal. It is also reported that 75% of white infants are placed to sleep in the supine position, while only 53% of black infants are, and that there is greater incidence of bed sharing among black infants than in other groups.[35] J.B. was placed on his back and was in his own crib.

3. Third Risk Factor: Exogenous Stressor(s)

The third and last factor is referred to as exogenous stressor[s] present at the time of death.[36] These stressors identified in the literature include "prone sleep position, face-down position, covered face in the supine position, soft bedding, bed sharing, over-bundling, elevated room temperature, and minor infection at the time of death."[37] Virtually every SIDS case includes one or more exogenous stressors, implying that they act as "triggers" for SIDS.[38] Studies also show that often multiple risk factors are present in a given SIDS case. Trachtenberg et al. found that "at least 2 extrinsic risk factors" were present in a majority of 568 cases reviewed. *Id.* at 632.

Dr. Kinney has hypothesized that exogenous stressors "lead to asphyxia, hypoxia, hypercapnia, or thermal imbalance requiring intact brainstem defense systems to protect against lethal consequences."[39] Non-vulnerable infants are generally able to recover from these conditions, but vulnerable infants are less able to recover and succumb to SIDS. *Id.* at 521.

As a result of their research, Dr. Kinney and her team proposed the Triple Risk Model to explain the occurrence of SIDS. Dr. Kinney's group then proposed the "Back to Sleep Campaign" in the early 1990s in which they recommended that babies always be put to sleep on their backs (supine) on a firm mattress, without pillows, blankets, toys, bumpers or other items that could potentially obstruct breathing. The prone or face-down sleeping position was considered to make an infant particularly vulnerable because an infant in the first six months of life with one or more intrinsic defects may re-breathe excess carbon dioxide and lack the corrective arousal mechanisms during sleep that would prevent a fatal outcome. Generally, the accumulation of excess carbon dioxide in the body causes signaling to breathe, thereby exhaling

carbon dioxide and inhaling room air containing oxygen. During sleep it is thought that excess carbon dioxide normally causes a person to turn the head toward fresh air and become aroused from sleep. When those mechanisms fail, the gasp reflex is triggered, which brings in oxygen and resets the rhythm of breathing. In SIDS, the dominant theory is that all of these mechanisms fail, leading to death.

The Back to Sleep Campaign has succeeded remarkably in reducing the number of SIDS deaths in the United States by approximately 50%.[40] In the U.S., the rate was reduced from more than 1 per 1,000 infants to 0.53 per 1,000, the current rate where it has plateaued. *Id.* However, SIDS remains the leading cause of post neo-natal infant death in the United States, raising some of the questions at issue in this case. *Id.* The emphasis has continued to be on the cardiorespiratory failure explanation of SIDS. Research has indicated that prone sleeping position increases the risk twofold or more. *Id.* They concluded that those not found prone sleeping were subject to alternative SIDS risk factors. *Id.* at 635.

The Trachtenberg article concluded that virtually all SIDS infants have at least one risk factor, and the majority have at least one intrinsic risk factor and two extrinsic factors. *Id.* The article also notes that the American Academy of Pediatrics risk reduction guidelines also include recommendations against side-sleeping and bed-sharing, and suggest a separate but proximate sleeping environment and pacifier use. *Id.* at 636. The data from the Trachtenberg study found a decline in prone position sleeping from 84% in the pre-Back-to-Sleep era to 48.5% in the post-era, but it also found that in the post-era 17.3% of SIDS infants were found on their sides while 22.6% were initially placed on their sides. *Id.* at 634, Table 2. Interestingly, 29% of the SIDS babies in that study were found supine while 41.7% were placed on their backs, suggesting that SIDS is not exclusively caused by prone sleeping. *Id.* at 632.

The Trachtenberg and Kinney articles emphasize the belief in the medical community that SIDS is multifactorial. As Trachtenberg noted, they were only able to evaluate which SIDS risk factors are most common, not which factors raise the odds of SIDS most significantly. *Id.* at 635. The authors suggest that the number of risks is probably underestimated and that "the majority of SIDS infants were subject to at least two extrinsic risk factors, suggesting that SIDS occurs from the simultaneous occurrence of multiple factors, rarely just one." *Id.* Additionally, Dr. Kinney has noted that under the Triple Risk Model, only infants with an underlying brainstem disease process die of SIDS, which explains why all infants who are placed prone to sleep or who bed share do not die of SIDS.[41] She states that SIDS essentially represents the occurrence of "the biologic version of the perfect storm in which the chance combination of multiple events is far more powerful than each individual event alone." *Id.* at 539. She suggests a possible scenario in which a child with the underlying brainstem deficit, during the critical developmental period, is exposed to excess carbon dioxide while he is sleeping. This may be based upon his sleeping position or he may have an issue with the laryngeal chemoreflex stimulated by reflux of gastric contents *or may have a mild infection with fever* causing the laryngeal chemoreflex induced apnea to be inordinately prolonged by mild hyperthermia" *Id.*

[40] Trachtenberg, Kinney, et al. (2012), Exhibit C-11 at 631.

[41] Kinney et al. (2009), Exhibit 13-H at 521.

(emphasis added). In this scenario, "if the infant's ventilator response to the progressive hypoxia and hypercapnia during the apnea is depressed, and if the hypoxic gasping and/or arousal mechanism is abnormal, oxygen lack from uninterrupted apnea results. Ultimately, death occurs *within minutes to hours*." *Id.* (emphasis added).

Respondent filed the article by Trachtenberg et al., which emphasized that they could find no positive correlations between risk factors or risk clusters but it appeared that any combination of risks together increased the odds of SIDS. The fact that most infants have at least two extrinsic risk factors suggests that SIDS occurs as a result of the occurrence of multiple factors and rarely just one.[42] The Kashiwagi article[43] filed by petitioners suggests that vaccines provoke an inflammatory cytokine response similar to that provoked by a mild infection. Petitioners theorize that these cytokines travel to the brainstem and further suppress the function of the already impaired medullary 5-HT system in a subset of SIDS infants.

a. Cytokines, Mild Infection and Vaccines

Relevant to this case, in a 2009 article in the New England Journal of Medicine, Kinney and Thach stated, "A causal role for mild infection in sudden infant death is suggested by reports that in approximately half of SIDS cases, the infants have a seemingly trivial infection around the time of death, as well as mild tracheobronchial inflammation, altered serum immunoglobulin or cytokine levels and the presence of microbial isolates at autopsy. In infants who die unexpectedly of infection, the given organism may precipitate a lethal cytokine cascade or toxic response."[44] The question arises as to whether the cytokine response stimulated by vaccination can have the same effect as a mild or trivial infection in a baby who presumably has a defect in the medullary 5-HT system.

The role of cytokines stimulated by either mild infection or by vaccination is central to petitioners' theory in this case. Approximately 50% of SIDS babies have been found in multiple studies to have had mild or even "trivial" infections, primarily of the upper respiratory tract at the time of death. In this case, J.B. was documented the prior day as being healthy with patent nares, normal turbinates, and clear chest, but during the 28 hours after the vaccine he was reported to have a fever, which is generated by cytokine signaling. He also was distant, quiet, and would not eat, according to his parents. The case raises the issue of whether inflammatory cytokines stimulated by the innate response to the vaccines triggered the fever and his fussiness, and ultimately suppressed his 5HT system sufficiently so that he could not process the carbon dioxide in his system. The question of whether inflammatory cytokines stimulated by the innate response to the vaccine could have been the trigger that led to his death was central to the testimony and much of the literature submitted by the parties particularly in light of the clear medical evaluation on the day of the vaccination and a fever within hours afterward.

[44] Kinney & Thach (2009), Exhibit A-4 at 2.

As Dr. Kinney and her colleagues explained in 2011: "Cytokines orchestrate immune responses to microbial invasion and other insults and coordinate these responses with those of other physiological systems, including the autonomic nervous system, in the protection of the organism against tissue injury. They also mediate sickness behavior, including fever, anorexia, excessive sleepiness, blunted arousal, deep rest respiration, and lowered heart rate, which is thought to protect the organism during systemic illness by dampening excessive metabolic demands and thereby speeding repair and recovery - a form of homeostasis."[45] "Cytokines determine this sickness behavior by binding to endogenous cytokine receptors on neuronal populations in the hypothalamus and/or brainstem that mediate respiration, autonomic function, satiety, sleep, and arousal." *Id.* at 190. The cytokines which act within the brain in response to tissue injury are produced by astrocytes, and endothelial cells, microglia, *and/or peripheral immune cells* which enter the brain in response to binaural signals of tissue damage." *Id.* (emphasis added). During infection, peripherally produced IL-6 may cross the blood brain barrier and bind to IL-6 receptors on 5 HT neurons that mediate homeostasis in response to the infectious stressor and potentially mediate sickness behavior. *Id*. at 191. The role of pro-inflammatory cytokines in the pathology of SIDS is thought by multiple authors to be a potentially critical factor in tipping the molecular balance in the underdeveloped brainstem leading to death in infants in the vulnerable time period. IL-1β, IL-2, and IL-6 are pro-inflammatory cytokines that have been studied in connection with SIDS leading to theories about their potentially neuro-modulatory role in SIDS babies.

Kadhim et al. described a distinct cytokine profile in a SIDS brain in a study comparing SIDS brains with non-SIDS brains. The non-SIDS brains were from infants who died of known causes, including AIDS, cirrhosis of the liver, mononucleosis, purulent meningitis, and congenital heart disease with post-operative acidosis-shock. He found an over-expression of interleukin 1β in arcuate and dorsal vagal nuclei in all SIDS victims. In arcuate nuclei, high levels of interleukin 1β were detected in 17/17 SIDS brains vs. only 1 of 6 non-SIDS brains.[46] In dorsal vagal nuclei, interleukin 1β was also detected in high levels in 17 of 17 SIDS brains vs. only 2 of 7 non-SIDS brains. *Id.* Kadhim found a "region-specific pattern of cytokine expression in [the arcuate and dorsal vagal nuclei] of SIDS brains compared to non-SIDS brains." *Id.* at 1259. Kadhim theorized: "cytokines could exert neuromodulatory effects. Infectious inflammatory conditions and injury to the brain could up regulate pro inflammatory cytokines and produce functional alteration ... Cytokine/neurotransmitter interactions could therefore modify vital CNS functions." *Id.* Kadhim et al. further concluded that IL-1 causes prolonged apnea and depresses respiration, and that the brain appears to be less effective than the peripheral nervous system in inducing IL-1 antagonists to control IL-1 action.

[45] Kinney et al. (2011), Exhibit 13-F at 189.

[46] Kadhim, H. et al., *Distinct Cytokine Profile in SIDS Brain: A Common Denominator in a Multifactorial Syndrome?*, 61 Neurol. 1256 (2003), Exhibit 13-L at 1256.

In a second study from 2010, Kadhim focused on the expression of IL-2 in 28 autopsied infants who died at less than one year of age.[47] He described IL-2 as major immune-related cytokine that was originally thought to be a T-lymphocyte growth factor but is now recognized to have a wider spectrum of functions, targets and sources. *Id.* The study compared 18 SIDS brains to those of infants who died of diverse severe pathological conditions including infectious, hemodynamic, metabolic or other serious genetic conditions. In the severely ill children (non-SIDS), they found that IL-2 was preferentially expressed in specific neuronal centers within the brainstem (SNT-solitary nucleus tractus and TSNT-spinal trigeminal nucleus/tractus) in 10 of 10 cases of the fatally sick (non-SIDS) children and in the arcuate and dorsal vagal nuclei in 8 of 10. "Examination of the brainstem in the SIDS group showed a topographically similar profile with an equally intense immune reactivity within the very same neuronal circuits; precisely the strongly expressed cytokine labeling of IL-2 in SNTT and/or TSNT was observed in 17 out of 18 cases that constituted the 2nd study group (SIDS). IL-2 was also notable in the arcuate nucleus and dorsal vagus nucleus in 17 cases. These brainstem neuronal centers are known to be intricately implicated in autonomic control of vital homeostatic functions namely cardiorespiratory control mechanisms."[48] The authors concluded that it was not surprising to see the intense IL-2 expression in the infants who were severely ill before they died, but the SIDS victims are generally free from apparent potentially fatal conditions. "The SIDS victims often have preceding mild infectious/inflammatory conditions (like coryza[49]/mild upper respiratory infections, soft stools mild gastroenteritis, *postvaccinal fever*, etc.). Such trivial infections were found to induce a hypertuned immune/inflammatory response including high levels of immune inflammatory cytokines." *Id.* at 122. (emphasis added). Kadhim reviewed the Triple Risk Model, placing his study findings with regard to inflammatory cytokines in that framework; "Such mild infectious inflammatory conditions (extrinsic environmental stressors), if contracted in a vulnerable infant (intrinsic factors including prematurity and gene polymorphisms) during a critical developmental period whereby brainstem command centers undergo rapid maturation could provoke exaggerated immune responses with over expression of cytokines. We believe that this hypertuned immune response is behind the high IL-2 immune-reactivity we detected in situ in the brainstem of these victims." *Id.* at 125. Kadhim also noted that while pro-inflammatory cytokines have immune function, it is noteworthy here that cytokines have *neuro-modulatory effects* whereby they can modify neurotransmission. *Id.*

The role of mild infection was further discussed in an article by Rognum et al.[50] The Rognum group compared three groups of deceased infants. The group of 25 SIDS cases was selected from those subjects in whom no explanation for death was found. A second group died from known infectious causes and the third control group died primarily from violent causes

such as drowning, suffocation or strangulation. *Id.* at 522. The IL-6 levels were significantly higher in SIDS subjects than in controls. The IL-6 levels in SIDS infants with minor infection were comparable to those infants who succumbed to severe infection. *Id.* at 520.

Rognum et al. wrote: "We previously showed that IL-6 is elevated in the cerebrospinal fluid of SIDS infants and that this elevation may be induced by a peripheral immune reaction. Approximately one half of the SIDS cases we have studied show signs of a mild infection, but IL-6 levels are comparable to those of infants succumbing to severe infection, suggesting an overreaction to the slight infection." *Id.*

According to Rognum: "In addition to its pro-inflammatory properties, IL-6 exerts effects outside the immune system. Non-immune cells including neurons can produce and secrete IL-6 and express its receptor. Of critical relevance to the premise that cytokines interact with central neurons to affect their function, IL-6 is shown to be important in neuronal development in the modulation of neuronal signaling." *Id.* "A major site of 5-HT cell bodies in the human infant brainstem is in the arcuate nucleus, the putative site for central carbon dioxide (CO2) sensitivity in humans and animal models. In this regard the synergistic effect of prone sleeping and infection on SIDS risks may be a set up for CO2 accumulation, as both rebreathing in the face down prone position and increased metabolism due to infection may increase CO2 levels. Death may be triggered if CO2 sensing regions in the brainstem, such as the arcuate nucleus, are compromised and cannot mount an arousal response to protect the infant from the dangerous situation. The arcuate nucleus is of particular interest in the study due to the previous finding by others of high neuronal IL-1β immunoreactivity at this site in SIDS cases compared to controls." *Id.*

Rognum et al. did identify one particular confounder to this theory in that they found that the mean IL-6R (receptor) intensity grade in the arcuate nucleus was significantly higher in the SIDS group than in the control group but the gp130 transducer was significantly higher in the infection group but less so in SIDS relative to the controls. While Rognum et al. acknowledged difficulty in grading the immunosensitivity of IL-6R and gp130 in this study due to its small size as a major limitation in the study, the result led the authors to hypothesize that the increased expression of IL-6R in the arcuate nucleus may be a compensatory mechanism as defective arcuate neurons may require excessive IL-6 stimulation in order to respond to altered carbon dioxide levels and there may be an inability in the SIDS babies to upregulate gp130 to mount an effective response.[51] *Id.* at 528. Nevertheless, the study concluded that abnormal IL-6R expression was found in the arcuate nucleus of SIDS babies 44% of whom had mild infections prior to death and thereby "provides evidence for aberrant interactions in SIDS infants between Il-6 and the arcuate nucleus, a key medullary 5-HT related region involved in protective responses to hypercapnia, potentially induced by the combined effect of prone position and mild infection." *Id.* at 529.

[51] Dr. Miller explained that gp130 is a second messenger in the cell that takes the message that the receptor has bound something and does something with it to take (tell) the cell to do something else. This is a very common mechanism in membrane signaling, that there's a second messenger system that then tells the cell to do something. Tr. p 32.

Rognum et al. concluded: "The key finding in this study is abnormal IL-6R expression in the arcuate nucleus in the SIDS cases, 44% of whom had signs of mild infection immediately prior to death. *Id.* at 528. Rognum further noted that the arcuate nucleus contains 5-HT and glutamatergic neurons that have been shown in animals to be critical to chemosensitivity. It is also the site for several neurotransmitter abnormalities in SIDS, including in 5-HT, muscarinic and kainite receptor binding. It is well documented that CO2 levels are elevated during severe neonatal infection and, interestingly, even mild upper respiratory infection may increase CO2 levels in infants over 3 months of age. Animal studies indicate that the *CO2 elevation can be attributed to a hyper metabolic state induced by proinflammatory cytokines*." *Id.* at 527-28 (emphasis added).

Kashiwagi studied the production of cytokines after vaccination in 61 vaccine recipients with fever and 18 without fever within 24 hours of vaccination. Blood samples were taken within 48 hours of vaccination in both groups. He reviewed the role of the innate immune system in responding to vaccination noting that the activation of the innate immune system including the enhanced production of inflammatory cytokines is indispensable for immunogenicity and these cytokines may be related to the occurrence of adverse events.[52] This group found that cytokine production began about 6 hours after the stimulation by a single or combination of vaccines and *increased for 24 hours, showing the same level afterward. Id.* at 679. They found that higher levels of IL-1β, IL-6, G-CSF[53] and TNF-α were produced with the concurrent stimulation by multiple vaccines than with the single vaccine in PBMC cultures (peripheral blood mononuclear cells - obtained from young infants in this study). *Id.* at 679. Higher levels of IL-6, IL-10, IL 12, G-CSF, IFNγ and TNFα in both the febrile and non-febrile groups were found after vaccination and G-CSF was significantly higher in the febrile group. *Id.* at 680. He noted that innate immune systems are not fully functional at the time of birth. Kashiwagi's group found that TLR (Toll-Like Receptors) stimulated the production of pro-inflammatory cytokines (specifically IL-β, IL-6, and IL-8) which was markedly higher in neonates than in adults. He also found that higher levels of IL-1β were produced in PBMC cultures stimulated with PCV7 than with DPT or Hib. Hib induced higher levels of IL-6 and TNF-α. IL-1β increased in PBMCs stimulated concurrently with Hib/PCV7 and DPT/Hib/PCV7 with similar patterns of TNF-α and G-CSF. However, when blood was drawn 48 hours post-vaccination, IL-1β was not found. *Id.* Dr. Miller theorized that IL-1β rises rapidly and then disappears by 48 hours whereas the other inflammatory cytokines have a longer half-life. Tr. 47

Kashiwagi noted: "All effective vaccines induce the production of cytokines or chemokines, which modulate immunogenicity and are also involved in inducing adverse events, such as systemic febrile illness and immunotoxicity. In this standpoint, IL-6, IL-10, IL-12, G-CSF, IFN-γ, and TNF-α were detected in both febrile and non-febrile groups after vaccination in comparison with those in normal subjects." *Id.* at 683. Inflammatory cytokine profiles after vaccination were similar to the outpatient group infected with the influenza virus. *Id.*

[52] Kashiwagi, et al. (2014), Exhibit 17 at 678.

[53] G-CSF is granulocyte colony stimulating factor *Dorlands* at 767- It is now classified as another cytokine. Tr. 47.

Vege and Rognum reviewed the literature and their own work and noted that "in 1995 they found that half of the SIDS victims had elevated levels of interleukin-6 (IL-6) in their cerebrospinal fluid (csf). The concentrations of IL-6 in SIDS infants were comparable to those we found in infants dying from infectious diseases like meningitis and septicaemia." They concluded that there were two groups of SIDS infants—one with IL-6 levels similar to infants dying of severe infections and another having low levels similar to those dying violent deaths. They hypothesized that one group of SIDS deaths may be attributable to sleep position and another to an uncontrolled inflammatory response to infection, predominantly occurring at night when cortisol levels, another mechanism for controlling inflammatory responses, are low.[54]

Others have studied cytokine expression in animals. Brambilla demonstrated in animal studies that Interleukin 1 (IL-1) inhibited firing of excitatory or wakefulness producing neurons in the dorsal raphe nucleus and enhanced activity of GABAergic or inhibitory neurons and, as such, induces enhancement of NREM sleep.[55]

Respondent submitted an article by Siljehav, Hofstetter et al. which sheds additional light on the possible mechanism involved with apnea in infants occurring in response to infection. These authors wrote: "Our data suggest that PGE2[56] induced by IL-1β as well as hypoxia selectively modulates respiration-related neurons in the rostral ventrolateral medulla, including the preBotzinger Complex via EP3R. Other neuromodulators, including PGE1, have been shown to inhibit preBotC neurons and slow respiration-related rhythm and preBotC lesions may disrupt anoxic gasping and evoke central apneas and ataxic breathing. Moreover, these respiration-related neurons were recently shown to be critical for adequate response to hypoxia, maintaining brainstem homeostasis with gasping and autoresuscitation and thus restoring oxygen levels. PGE2-induced depression of this vital brainstem neuronal network, e.g., during an infectious response, could result in gasping and autoresuscitation failure and ultimately death."[57] The model of the IL-1β induced respiratory depression and autoresuscitation failure via a PGE2 –mediated pathway was described. "During a systemic immune response, the proinflammatory cytokine IL-1ß is released into the peripheral blood stream. It binds to its receptor (IL-1R) located on endothelial cells of the blood brain barrier. Activation of IL-1R induces the synthesis of PGH2 from arachidonic acid via COX-2 and the synthesis of PGE2 from PGH2 via the rate limiting enzyme mPGES-1. PGE2 is released into the brain parenchyma and binds to the EP3R located in respiratory control regions of the brainstem, e.g., nucleus tractus solitarius and rostral ventrolateral medulla. This results in depression of central respiration-related neurons and

breathing, which may fatally decrease the ability to gasp and autoresuscitation during hypoxic events." *Id.* at 9898.

Stoltenberg[58] experimented on piglets and concluded IL-1 stimulates the release of beta endorphin and indicated that his group had shown that the level of beta-endorphin in cerebral spinal fluid correlates strongly with the duration of apnea. Furthermore IL-1β stimulates GABA transmission and hence increases the inhibitory postsynaptic function by opening of chloride delective channels, and this will reduce the activity in the central respiratory neurons and may produce hypoxia. He concluded that intravenous and intrathecal injections of interleukin 1β in piglets' prolonged apnea and modified autoresuscitation. Such a mechanism may play a role in depressing respiration in some infants dying of sudden infant death syndrome. *Id.* at 427.

In a study looking at the role of vaccination in producing apnea, bradycardia and oxygen desaturations in pre-term infants who received first DPT (whether whole cell or acellular pertussis, inactivated polio and Haemophilus influenza B), Lee found elevations in apnea, bradycardia and desaturations defined as cessation of respiration for 20 seconds, with a heart rate less than 100 and oxygen saturation less than 85%. Almost half had adverse cardiorespiratory events in the 72 hours post-vaccination which was statistically significantly higher than the control group which did not receive a vaccination in the prior 72 hours.[59]

Schulzke also studied apnea and bradycardia in pre-term infants, not on oxygen or respiratory support but in the NICU when they received pentavalent or hexavalent vaccines. Rate of increased apnea and bradycardia (defined the same as by Lee) was 13% in otherwise stable infants. Infants received ventilatory support and recovered. Events occurred between 8 and 24 hours after vaccination with onset of fever between 6 and 24 hours post immunization. [60]

B. SIDS Epidemiology

Although epidemiology is not required to demonstrate entitlement to compensation in the Vaccine Program, the parties submitted multiple articles, primarily from European studies, which looked at the question of the possible relationship between vaccination and the incidence of SIDS, as well as several articles that reported on cases. Articles by Venneman[61], Jonville Bera, Traversa, VonKries, Goldman, and Kuhnert studied the question of vaccine causation in SIDS by various methodologies all of which described their own limitations. Others by Ottaviani and

Zinka discussed individual cases of unexplained deaths occurring in close temporal proximity to receipt of vaccinations.

Goldman looked at VAERS data from 1990 to 2010 for hospitalizations and deaths after vaccinations and found a statistically significant positive correlation between mortality and receipt of five to eight vaccines compared to one to four.[62] (J.B. received 7 counting DTaP as three as the study did). Traversa conducted a large study using data from the Italian health system where vaccines are offered for free and the belief is that 95% of children are vaccinated. The study found a statistically significant relative risk for death in the first seven days after vaccination for the first hexavalent vaccine (six vaccines) but not after subsequent doses.[63]

Kuhnert did a review of studies from Germany, England, and New Zealand and critiqued the case control methodology through the use of the self-controlled case series method (SCCS). It concluded that the re-analysis using the latter method showed that the risk of SIDS was neither increased or decreased in SIDS cases or controls during the early post-vaccination periods but did "provide more detailed insights into the methodological pitfalls of such analyses using conventional case control methods."[64] Dr. McCusker testified that the Kuhnert study looked at three different studies and applied 39 statistical tests to them. She read the study as concluding that despite the application of multiple statistical post hoc tests, they still did not see anything. Tr. 236.

Other papers submitted in evidence included Zinka[65] reporting on six deaths in Germany within 48 hours of receipt of hexavalent vaccines. Kries[66] reported on a slight elevation in day one in the first year of life after one particular hexavalent vaccine but a significant increase in deaths in the second year of life after receipt of that vaccine. Ottaviani[67] did a detailed case study of one young child who died three hours after receipt of a hexavalent vaccine at 3 months of age. He did a detailed autopsy identifying bilateral hypoplasia of the arcuate nucleus. He concluded that this death could be consistent with the Triple Risk Model or be one of the SIDS

[67] Ottoviani, G. et al., *Sudden Infant Death Syndrome (SIDS) Shortly After Hexavalent Vaccination: Another Pathology in Suspected SIDS?*, 448 Virchows Arch. 100 (2006), Exhibit 13-T at 4.

"grey zone" cases in which it is difficult to establish if the pathological findings were sufficient to cause death.

Each of the studies contained considerable acknowledgment of its own methodological deficiencies that may have affected the results. In different papers, these included inclusion without autopsies, small samples, comparing SIDS victims to living children rather than vaccinated SIDS to unvaccinated SIDS, as well as having no control group or having potential underreporting as in VAERS. The Kuhnert paper which analyzed three other case control studies including Venneman, said, "The small number of cases is a problem with the three case control studies, particularly in view of the short time periods under investigation. This problem is illustrated by the very broad confidence intervals of estimates that are only related to the events of the first few days."[68]

Dr. Miller criticized several of the studies for failing to use cases that were verified by autopsy, that the Vennemann study compared a new hexavalent vaccine to older vaccines rather than asking the question as to whether vaccines regardless of new or old could be associated with SIDS, and used data based on the number of vaccines sold rather than administered. Tr. 70-74. He noted that the IOM concluded that the evidence that it reviewed was insufficient to accept or reject causation. Tr. 387. In his report, Dr. Miller explained why it is difficult to do reliable epidemiological studies of SIDS. He said, "[I]f the risk for SIDS is present only in those infants who are already vulnerable because of a pre-existing brainstem abnormality, then no retrospective (or prospective) epidemiological study not grounded in a thorough neuropathological examination of all of the supposed SIDS cases would be likely to identify that putative causal relationship." Exhibit 13 at 5. He observed that J.B. would be one of those not counted as he did not have a complete neuropathological autopsy. *Id.* at 6.

Dr. McCusker criticized some studies as case reports or having no control group. She looked to Kuhnert which incorporated Vennemann to argue that there was no significant finding that SIDS occurred more often than chance. Tr. 228.

The Vaccine Program does not require epidemiological evidence and the studies presented contained multiple methodological flaws, and did not tend to shed much light on the question at issue, that is, whether the death of the child in this case was caused or triggered by the vaccinations received the day before. Thus the studies were read and considered and credited to show that vaccines are generally safe, but were specifically unpersuasive as to whether they are on rare occasions the exogenous factor resulting in the perfect storm in a child with a defective arcuate nucleus or other 5HT structure during the vulnerable period of life. They were also unpersuasive to reject causation as they frequently showed some temporal correlation to the receipt of vaccines even if those correlations were not found to be statistically significant.

C. Expert Opinions

1. Petitioners' Expert Douglas C. Miller

Dr. Douglas C. Miller earned his bachelor's degree from Williams College and his medical degree from the University of Miami School of Medicine in 1978.[69] He received a Ph.D. in Physiology and Biophysics from the University of Miami in 1980. *Id.* Dr. Miller was a resident at Massachusetts General Hospital from 1980-1984, focusing in the areas of anatomic pathology and neuropathology. *Id.* He currently serves as a clinical professor of pathology and anatomical sciences, as well as the program director of pathology residency, at the University of Missouri School of Medicine. *Id.* at 3. He also serves as an associate medical examiner for Boone, Callaway, and Greene Counties in Missouri. *Id.*; Tr. 10. Dr. Miller has been a full-time faculty member at the medical schools at Robert Wood Johnson in New Jersey, New York University, and the University of Missouri. He has published over 150 articles in medical journals and is the author of a textbook on neuropathology.

i. *Althen* Prong One: Medical Theory

Dr. Miller, consistent with the dominant literature in the field, proposed the Triple Risk Model of SIDS as the framework for his theory of causation.[70] Tr. 19. As explained above, this model first provides that SIDS can occur only when an infant is in a critical developmental period (the first year of life). Tr. 20. Second, SIDS can occur only to an infant who is inherently vulnerable in some way. *Id.* Third, the infant must encounter an exogenous stressor. *Id.*

Dr. Miller explained the normal physiological process for handling carbon dioxide and stimulating breathing. He said if the carbon dioxide levels rise above a normal threshold to an abnormal threshold, a normal brainstem's response – in this age group – is mediated by the arcuate nuclei alone. The excess carbon dioxide stimulates other neuronal systems to alert the cervical spinal cord motor neurons to tell the diaphragm and other muscles of respiration to contract, at the same time signaling up through other mechanisms in the basal forebrain, underneath the lower part of the frontal lobes, to wake up. In general, there is arousal and there is deeper breathing to blow off the carbon dioxide, and if it is position-related, the infant would also move so that homeostasis is restored. Tr. 29. He explained that this process is dependent on serotonin, an excitatory neurotransmitter, which stimulates the cells to which it signals to fire more rapidly to increase breathing or arousal. Tr. 28. That is in contrast to GABA, which is inhibitory and balances the excitatory effect of serotonin. *Id.*

Dr. Miller explained that the majority opinion in the medical community is based principally but not exclusively on work done by Dr. Hannah C. Kinney, in a series of papers that stretch back more than 25 or 30 years and has been verified by other people. She has shown that "the medulla, the lowest part of the brainstem, in infants who have died of SIDS and have been autopsied and have had the appropriate examinations is defective. In particular, it has a defect in

[69] Curriculum Vitae of Dr. Douglas C. Miller, Exhibit 14 at 1.
[70] Kinney, H.C. et al., *Medullary Serotonergic Network Deficiency in the Sudden Infant Death Syndrome: Review of a 15-Year Study of a Single Dataset*, 60 J. Neuropathol. Exp. Neurol. 228 (2001), Exhibit 13-C.

a set of nuclei [or] groups of neurons, which use, as a neuro-transmitter a molecule called serotonin … which is also known as 5-hydroxytryptophan and which is abbreviated as 5-HT." Tr. 19. He further explained that Dr. Kinney and others have shown various deficits in infants, but the ones who die of SIDS have in common deficits in either the number of 5-HT neurons or in receptors for serotonin on those neurons or various other associated abnormalities. All of these suggest that the infants who die of SIDS usually die in their sleep and usually after an episode of apnea – that is, the cessation of breathing with elevated carbon dioxide in the blood to which they fail to respond normally. They fail to respond because the 5-HT system is the system which, in that age group, allows for arousal and increased breathing to respond to that kind of a danger. Since they fail to respond, they do not wake up, they do not breathe, and they die. Tr. 20.

Dr. Miller theorized, consistently with the research of Dr. Kinney and others, that many SIDS infants have "abnormalities of the medullary serotonergic synaptic systems governing respiration and arousal from apnea." *Id.* at 6. He said that "we have data that at least 70 percent of infants who ultimately die of SIDS have a defective 5-HT system which is way over half and thus statistically likely that [J.B.] was one of those." Tr. 62. Dr. Miller said, "It's really a neurochemical question. These molecules (cytokines) are provoked by an immune response, an innate immune response, originally in the periphery, but their effect in terms of SIDS is a neurochemical effect, affecting synaptic transmission and neuronal activity of the 5-HT system and maybe the GABA system in the medulla, and that's a neurochemical synaptic effect." Tr. 61. He stressed that the role of the cytokines in SIDS was in their capacity to modify normal neurologic function rather than being purely immune in nature. He assumed that J.B. was an immunologically normal child, who when given a vaccination would have had an appropriate immune response, including the production of cytokines such as the ones identified by Kashiwagi et al. Therefore, he would expect the level of cytokines to be transiently increased after vaccination. Tr. 62. "These cytokines would have been circulating in his body after vaccination and we have direct evidence that there was some cytokine-central nervous system interaction in that he had fever. Then there is a logical chain of events that says cytokines depressed the 5-HT system in a defective medulla leading to SIDS during sleep." Tr. 62-63.

Dr. Miller stated that research is still identifying all of the exogenous stressors for SIDS. Tr. 44. He opined that one very well-recognized exogenous stressor for SIDS is mild infection. Tr. 45. Some of the estimates indicate that 40 - 50% of SIDS victims have had a very recent or current mild upper respiratory infection (URI) at the time of death. Tr. 45. He said that it is explicit in the literature from Dr. Kinney's laboratory and others that what happens with mild infections is that the response to the infection involves the production of certain cytokines and that those cytokines can act on the central nervous system. He presented a theory: that a mild upper respiratory infection can act as a neurochemical stressor by prompting the upregulation of cytokines, which he theorizes are detrimental in two ways. He said that an infection could cause fever, an extrinsic risk factor, and can cause elevated IL-1β levels, which would further depress a defective medullary 5-HT system. The system would then be incapable of responding to excess carbon dioxide, resulting in death. Tr. 46.

Dr. Miller cited several studies, including ones discussed above by Rognum, Kashiwagi, Kadhim, Brambilla, Stoltenberg, and Froen, that addressed the issue of cytokine stimulation and the function of cytokines entering the central nervous system. From these studies, Dr. Miller concluded that either mild URIs or vaccinations upregulate the production of cytokines, and these inflammatory cytokines, can "shut down" a structurally vulnerable 5-HT system and completely prevent it from restoring an infant's normal breathing. Tr. 35. In other words, the cytokines and the structural defect in the serotonin system acting in concert during a vulnerable period have the cumulative effect of causing SIDS by making the baby incapable of responding to excess carbon dioxide.

Dr. Miller noted that Kashiwagi found similar cytokine profiles in the recently-vaccinated population and those suffering from influenza, and further that the cytokine profiles were similar in post-vaccination babies whether they had a fever or not. Tr. 49. He explained that cells that are injured by infection initially produce an innate immune response. The cells of the innate immune system release cytokines which signal further activation of the adaptive immune system to respond to the foreign antigen. He said that there is a wide range of things that the cytokines produce, but the initial production is certainly peripheral where there is infection. Tr. 50. He testified that there is a whole lot of evidence that cytokines, produced peripherally, interact with the central nervous system and the easiest one to understand is the way fever is produced. He explained that fever is mediated by the central nervous system and specifically by the hypothalamus in the brain. The hypothalamus sets our body temperatures. It causes us to shiver if we are in the cold and need to warm up, or to sweat when we are overheated. Tr. 50-51. He further explained that if the fever was generated in response to an infection outside of the brain, such as in the case of a URI, there would be no inflammation in the brain as the brain is not infected, but there is still an interaction with the hypothalamus in the brain caused by cytokine signaling that causes fever in response to an infection outside of the brain. Tr. 51-52. Dr. Miller stated that he was not aware of any literature describing URI as a *mechanical* exogenous stressor and that in his professional experience conducting autopsies, he had never seen a URI "obstruction of the airway" that would be sufficient on its own to cause death. Tr. 46.

Dr. Miller stated that vaccinations can be an extrinsic risk factor in SIDS, as they prompt the upregulation of cytokines that, among other things, produce fever. Tr. 62-63. He testified that, based on the literature, there is a scientifically-plausible mechanism for vaccinations acting as the extrinsic risk factor in SIDS in much the same way as a mild infection. He explained that when you get a vaccination or a whole group of them at once, as J.B. did, it evokes a response which includes the production of cytokines, and that among those cytokines are IL-6, TNFα, and IL-1β. The physiological studies have shown that these can raise body temperature by producing fever, which is a risk factor, and they can inhibit the activity of 5-HT neurons in the medulla causing prolonged apneas and interference with autoresuscitation. Tr. 54, 62-63. When the vaccines are administered in the presence of the defects in the medulla, during the critical developmental period, they are likely to have a similar effect as mild infection that may cause a failure of the medullary response system and ultimately a death. Tr. 54.

Dr. Miller stated that mild upper respiratory tract infection is widely recognized to be an exogenous stressor under the Triple Risk Model. However, he acknowledged that there is not wide recognition, or a generally accepted theory, that vaccinations are an exogenous stressor. He stated that the Institute of Medicine concluded "the evidence is insufficient to say that there is an effect or there isn't an effect." Tr. 55. The Kinney research team has not studied the relationship between vaccination and SIDS. Tr. 60. Dr. Miller pointed to "multiple reports of similar cases of SIDS following various neonatal or infant vaccinations, mostly stressing the close temporal relationships between vaccination, increased cytokine production, and death from apparent SIDS as seen with this case."[71] He said that these individual cases and small case series show a "suspicious association between the timing of vaccination and the timing of SIDS deaths." Tr. at 55.

Summarizing his theory and review of the literature, Dr, Miller testified that the papers cited, including Kadhim, Kashiwagi, Rognum, Stoltenberg, and Froen, "verify the importance of the 5-HT system and its interactions with the GABA system in the medulla in terms of response to apnea or other respiratory-related insults." Tr. 34. Second, "they showed that there's an altered cytokine profile in SIDS cases versus non-SIDS cases, dying of other things, like drowning or trauma." *Id.* Third is the specific information on IL-1β, in that it inhibits the 5-HT system. *Id.* Therefore, in the context of SIDS, this suggests that if there is an elevated level of IL-1β to which the 5-HT neurons are exposed in an infant who already has too little 5-HT activity because of a defective brainstem, this additional cytokine effect would shut down the system such that it would not respond to other external stressors such as prone sleeping, nicotine, infection or fever. Tr. 34-35.

Dr. Miller addressed this analysis in terms of the cytokine reaction generated by vaccines. He said that we know that when a child gets a vaccine or a whole group of vaccines all at once, as occurred in this case, it evokes a response which includes the production of cytokines; that among those cytokines are IL-6, TNFα, and IL-1β. Those levels go up in the blood. We know that IL-1β can inhibit the activity of the 5-HT neurons in the medulla. If you take an infant who has a defective medulla with a defective 5-HT system already, you put in a stress situation with elevated carbon dioxide or low oxygen, and there is a vaccination which further shuts down the 5-HT system, and you can get a complete failure of response and therefore a death. He concluded that the mechanism is plausible. Tr. 54.

ii. *Althen* Prong Two: Logical Sequence of Cause and Effect

Dr. Miller then applied his theory to J.B.'s specific case. As an initial matter, he agreed with the decision to classify J.B.'s death as SIDS. Exhibit 13 at 1. Under the Triple Risk Model, Dr. Miller opined that J.B. was in the critical developmental period. Tr. 44. Statistically, he was inherently vulnerable. Dr. Miller opined that Kinney et al. have found that a significant proportion – up to 70% – of SIDS infants have abnormalities in the arcuate nuclei and other sections of the medulla. Exhibit 13 at 3. Dr. Miller said that there is also a Japanese study in

[71] Vege & Rognum (2004), Exhibit 13-Q; Kries et al. (2005), Exhibit 13-R; Zinka et al. (2006), Exhibit 13-S; Ottoviani et al. (2006), Exhibit 13-T; Traversa et al. (2011), Exhibit 13-U; Institute of Medicine, *Adverse Effects of Pertussis and Rubella Vaccines* (1991), Exhibit 13-V.

which that number went as high as 90 percent. Tr. 38. He testified that it is statistically most likely that J.B. also had this medullary 5 HT defect based on the Kinney data and other studies, even though it was not confirmed because the medical examiner did not sample that section of the brain. Exhibit 13 at 4-6; Tr. 37-38. Dr. McCusker agreed that "according to the Triple Risk theory, the brain problem must exist [in J.B.'s case]." Tr. 206.

A great many autopsies of SIDS infants outside of the research context do not section all of the necessary areas of the brain or view them histopathologically, which is typical of medical examiner autopsies. Tr. 16. Respondent's expert pathologist, Dr. Harris, acknowledged that based on Dr. Kinney's research, the majority of SIDS babies and up to 70% in some of her studies had an abnormality of the 5-HT system. Tr. 346. However, "[d]etection of these abnormalities requires special immune-histochemical research techniques not generally available for a 'routine' autopsy." *Id.* Dr. Miller testified that even in some autopsies where no structural abnormality was found in Dr. Kinney's research, when the full histochemistry was performed, there were still receptor binding deficits, such as in the IL-6 and gp130 studies. Tr. 41-42. Unfortunately, the types of tools she used including autoradiography and immunohistochemistry are not generally available for autopsies. Tr. 42-43.

Dr. Miller discussed the logical sequence of cause and effect between vaccines administered on September 2, and J.B.'s death on September 3. He opined that the vaccines acted as a critical external stressor in this case. He noted that J.B. was a "healthy infant… developing normally." Exhibit 13 at 4. He was "immunologically normal." Tr. 62. Therefore, after receiving vaccinations, his body mounted an innate immune response including the production of cytokines. Exhibit 13 at 6; Exhibit 16 at 1; Tr. 63. Those cytokines circulated in J.B.'s body, specifically into the central nervous system. Exhibit 13 at 6; Tr. 63. These peripheral cytokines interacted with the hypothalamus to provoke fever the night after the vaccinations, and the following day (before J.B.'s death). Exhibit 13 at 6; Exhibit 16 at 1; Tr. 62-64. "Those cytokines then acted in the brainstem which was already deficient in serotoninergic drive for respiratory effort, leading to an apneic episode from which he did not recover, i.e., SIDS." Exhibit 13 at 6; *see also* Tr. 62 (the cytokines "depress[ed the] 5-HT system in a defective medulla, leading to SIDS during sleep").

He opined that there was "no other demonstrable inciting event" for J.B.'s death. Exhibit 13 at 1. There was no evidence of the fever being related to anything other than J.B.'s vaccinations. Tr. 66. The autopsy did not identify any other infectious processes. Tr. 66.[72]

Dr. Miller was asked whether the pillow in J.B.'s crib increased the risk of SIDS. Tr. 87. Dr. Miller was not sure whether J.B.'s head was on the pillow. *Id.* He said, "If the pillow was by his feet, I don't think it's a risk factor." *Id.* A review of the investigation files indicates that there was no evidence as to whether or not his head was on the pillow. The only relevant evidence was that it was "a little crib pillow-very flat" and that his mother told the police that his nose or mouth were not covered when she found him about ten minutes after replacing his pacifier. Exhibit 7 at 5.

[72] Dr. Miller noted that there was bacterial growth and food particles in J.B.'s lungs and epithelial cells in the upper airways. He opined that this was not evidence of a separate infectious process. He agreed with the medical examiner that these were terminal or resuscitative events. Tr. 17-18; 66; 352-53.

On cross-examination, Dr. Miller stated that J.B. was placed on his back but was found on his side, which demonstrates that he was able to "move around." Tr. 92. However, J.B. did not pass away until "something else intervened." Tr. 85. Based on his theory and the temporal association, Dr. Miller opined that the vaccines were the intervening factor that caused J.B.'s death. Tr. 85; Exhibit 7 at 5. He said that he looks at SIDS cases individually and that it was his diagnosis that the vaccines contributed substantially to the death of J.B. in this case. Tr. 106-08.

iii. *Althen* Prong Three: Timing

With regard to timing, Dr. Miller stated several reports "have noted an elevated risk for SIDS within the first 48 hours following immunization, although this is not statistically significant." Exhibit 13 at 5. He stated that J.B. died within this 48-hour "window of elevated risk" following vaccination. *Id.*

Dr. Miller also stated that the available evidence is that foreign antigens, like those contained in vaccinations, activate the production of cytokines "within hours" and that production "peaks within 2 to at most 4 days." Exhibit 16 at 1. Thus, a vulnerable infant who receives vaccinations is most likely to suffer a fatal event if one is to occur "within the first 48 hours to at most 4 days." *Id.* Dr. Miller opined that J.B.'s death was "well within this vulnerable period." *Id.*

2. Respondent's Expert Dr. Christine McCusker

Dr. Christine McCusker earned a Masters in Molecular Virology in 1988, followed by an M.D. in 1993, at McMaster University, in Hamilton, Ontario. Exhibit D at 1. Her residency training was in pediatrics, at Montreal Children's Hospital, McGill University, from 1993-1996. *Id.* at 2. She was then a clinical fellow in allergy and immunology at McGill University from 1996-1999. *Id.* Dr. McCusker is board certified in pediatrics. *Id.* She is currently the division director of pediatric allergy, immunology, and dermatology at the Montreal Children's Hospital at McGill University Health Center and is the director of the Clinical Immunology Lab. Tr. 122. She has a wet lab that studies developmental immunology, which has peer-reviewed funding. *Id.* She also runs a clinical research program that uses databases to follow patients with primary immunodeficiency. *Id.* In addition, she sees pediatric patients at McGill Children's emergency room and at several allergy, immunology, and general pediatrics clinics. Tr. 124. Dr. McCusker also teaches medical students in the areas of immunology, dermatology, and malignant hematology. *Id.*

i. *Althen* Prong One: Response to Petitioners' Medical Theory

Like petitioners' expert Dr. Miller, Dr. McCusker accepted Dr. Kinney's formulation of the Triple Risk Model. Dr. McCusker agreed with Dr. Miller on the critical development period, and that an infant may be "vulnerable" because of a brain defect, premature birth, male gender, and/ or African American race. Dr. McCusker disagreed with Dr. Miller's opinion that upper respiratory infection, and by extension, vaccines, act as *neurochemical* exogenous stressors within the Triple Risk Model.

Dr. McCusker spent considerable time explaining why upper respiratory infection and other exogenous stressors, such as "being placed or found in a prone/ side-sleep position, found face down, head covered, sleeping on an adult mattress, couch, or playpen, soft bedding, bed-sharing, and signs of upper respiratory tract infection," are *mechanical*. Specifically, each one impedes an infant's ability to exhale carbon dioxide and inhale fresh oxygen, thereby increasing the risk of SIDS. Tr. 127-28.[73]

She opined that the prone sleep position is more widely recognized as an exogenous stressor for SIDS, but that the side-sleep position poses just as much risk. Tr. 131. She stated that breathing depends on "drop[ping] the diaphragm down and creat[ing] a negative airspace, [in which] the air comes rushing in." Tr. 130. An infant's body is not fully developed, so it uses "more than just the diaphragm" and "a lot of abdominal muscle to breathe." *Id.* An infant lying supine with the head back breathes most easily. *Id.* In contrast, an infant in either the prone or side-sleep position has more difficulty dropping the diaphragm and exhaling carbon dioxide. *Id.* Dr. McCusker also opined that the side-sleep position compresses "at least half your rib cage." Tr. 132. She stated that an infant's rib cage is "soft" and "very pliable." Therefore, it does not take much to influence the infant's ability to exchange air. *Id.* She also noted that an infant's breath is much more shallow and rapid than an adult's, and therefore the diffusion of exhaled carbon dioxide is less than in adults and rebreathing is more likely. *Id.* Theoretically, this means that an infant is at greater risk of re-inhaling expelled carbon dioxide. *Id.* Dr. McCusker acknowledged that the Back to Sleep Campaign previously advised parents to avoid all risk factors for SIDS, and that early research emphasized avoiding prone sleeping. *Id.* at 132-33. However, she said more recent studies looking "a little bit more closely" indicate that "prone and side-sleeping have equal risk." Tr. 134. She also stated that an infant learns to roll from the supine position to the side or prone position, but "usually not until somewhere between four and six months." Tr. 134-35. She did acknowledge, however, that the American Academy of Pediatrics does say that once a child is able to roll from his back to his side or to prone, then the parent should not disturb them. They should just have nothing else in the crib that could obstruct breathing. Tr. 135.

She also stated that gastroesophageal reflux is an exogenous stressor. Tr. 137. Specifically, an infant's airway and esophagus are linked at the back of the throat. *Id.* An infant may regurgitate and inhale at the same time, and therefore stop breathing momentarily. *Id.* at 138. If the infant neither swallows nor expels the food, his breathing will become obstructed and he will not recover. *Id.*

Dr. McCusker stated that bundling is an exogenous stressor and suggested several possible reasons why. *Id.* at 135. First, she opined that bundling decreases an infant's arousal, which helps the infant go back to sleep, but may increase the incidence of SIDS. *Id.* at 136. Second, a bundled infant may be less able to roll out of the prone or side-sleeping position. *Id.* Third, bundling may be an exogenous risk factor by leading to hyperthermia. *Id.* It should be noted that there is no evidence of bundling in this case, as J.B.'s father said he placed him on his back with a blanket across the midsection, but there was no indication that he was wrapped or bundled.

[73] Trachtenberg, Kinney, et al. (2012), Exhibit C-11.

Dr. Miller stated that hyperthermia was a term encompassing both high ambient temperature and fever. But Dr. McCusker disagreed. She testified that hyperthermia was high ambient temperature, and *hyperpyrexia* was fever. She stated that older literature listed both hyperthermia and hyperpyrexia as exogenous risk factors for SIDS. Tr. at 201, 287. However, she opined that newer literature, such as an article by Trachtenberg, lists hyperthermia as a risk factor for SIDS, but not fever. Tr. at 201, 287, 290. She agreed with this distinction. She reasoned that an infant experiencing hyperthermia tries to cool himself down. Tr. 289. To do so, the infant takes short, shallow breaths, which increase CO2 levels, which trigger the pathway to SIDS. Tr. 288, 295. She cited an article by Harper and Kinney, which provides that "vasodilation associated with overheating makes compensation for low blood pressure more difficult."[74] Dr. McCusker opined that fever is *not* a risk factor for SIDS. Specifically, she said in fever the body fasciculates or shivers – it makes small muscle movements that create friction, which generates heat inside the body. *Id.* at 184. The body cannot make these movements during deep REM sleep. Therefore, it stays in NREM sleep. *Id.* at 184-85. She opined that an infant generating or maintaining a fever, who does not descend into REM sleep, is less susceptible to SIDS. *Id.* at 202. It should be noted that nowhere in the submitted literature was an explicit distinction made between hyperthermia and hyperpyrexia, including in Trachtenberg or the Harper & Kinney article. Dr. McCusker is correct that in a 1992 article by Dr. Kinney, she mentioned "infection, fever and hyperthermia" as exogenous stressors.[75] Later articles generally reference hyperthermia and overheating. However, in a 2009 article, Dr. Kinney described a SIDS scenario in which in part she describes "an infant may be slightly febrile due to an otherwise trivial upper respiratory tract infection (3) as a consequence, the apnea component of the LCR is inordinately prolonged by mild hyperthermia,"[76] This reference would appear to suggest that the term hyperthermia may be more broadly inclusive.

Unlike Dr. Miller, Dr. McCusker characterized mild upper respiratory infection as a purely mechanical extrinsic risk factor for SIDS. Tr. at 127-28. She opined that an infant is accustomed to breathing through the nose, which enables uninterrupted bottle or breast-feeding. *Id.* at 138-39. When the nose is congested, she said, the infant still exerts significant effort to breathe through the nose, which elevates carbon dioxide. *Id.* at 139. If and when the infant finally resorts to breathing through the mouth, that is less effective and also increases the risk of respiratory distress. *Id.* at 140-43.

Dr. McCusker then spoke about cytokines. She asserted that cytokines serve a variety of positive functions in the healthy human brain. *Id.* at 145-58.[77] Researchers initially theorized that cytokines found in the brain, including IL-6, IL-1β, and tumor necrosis factor-alpha (TNF-alpha), had traveled there through the cerebrospinal fluid, to respond to inflammation in the brain. *Id.* at 151-52. However, research beginning in the late 1990s indicates that the brain itself

[74] Harper & Kinney (2010), Exhibit C-12 at 3.

[77] Besedovsky, H.O. and A. del Ray, *Central and Peripheral Cytokines Mediate Immune-Brain Connectivity*, 36 Neurochem Res. 1 (2011), Exhibit C-3.

produces cytokines. *Id.* at 152. Dr. McCusker cited articles reporting that inflammatory cytokines such as IL-6 and IL-1β regulate pain sensitivity, memory consolidation, stress, fever, and sleep. *Id.* at 152-56.[78] Ron-Harel wrote, "Pro-inflammatory cytokines are abundantly expressed in healthy brain and are involved in the regulation of many physiological functions such as pain sensitivity, memory consolidation and neural plasticity. Elevation in brain cytokine levels is considered part of the adaptive response to external stimuli. Exposure to acute psychological stressors by induction of adrenalin, noradrenalin and dopamine induces an increase in brain proinflammatory cytokines which modulate the neuroendocrine and behavioral response to the stressor. *Id.* at 3. She also cited an article by Moidunny et al. suggesting that cytokines including IL-6 may play a neuroprotective role in the brain after stroke or head trauma. *Id.* at 157.[79] Moidunny was studying the role of IL-6 in reducing glutamate excitotoxicity in stroke and head trauma with the goal of further research to identify additional pharmacological protection with IL-6 from glutamate neurotoxicity in these patients. Moidunny does not discuss SIDS or the role of peripheral cytokines in this article.

Dr. McCusker also cited to an article by Chen Miller, which discusses the role of Tryptophan Hydroxylase 2 which is a rate limiting enzyme in 5-HT biosynthesis. The article discusses advances in understanding Tryptophan Hydroxylase TPH and TPH2 which are critical for the initiation of the synthesis of 5-HT (serotonin) which modulates the stress response by interacting with the hormonal hypothalamic pituitary adrenal axis and neuronal sympathetic nervous system. The TPH2 mRNA expression is abundant in the raphe nuclei or regions containing raphe nuclei such as the pons and medulla, while it is detectable in a number of other regions including the cortex, hypothalamus, thalamus, hippocampus, amygdala and cerebellum. TPH2 gene expression is sensitive to stressful events including hemorrhage and hypoxia and involves neuronal and hormonal mechanisms. The article hypothesizes about the role of TPH2 and serotonin in response to stimulating events such as hypotensive hemorrhage, hypoxia and adverse events experienced in early life or as an adult, and a possible role in such conditions as PTSD but it was not clear how this paper directly addresses the issue of respiratory depression in SIDS. [80]

Dr. McCusker argued that the various animal studies cited by Dr. Miller were not relevant to cytokines' effect in infant brains *in vivo*. *Id.* at 162-87. First, she stated that the Brambilla article,[81] which showed that IL-1β depressed serotonin in rats' brain tissue, was not

relevant to sleeping infants. *Id.* at 185. Specifically, the Brambilla study submerged rats' brain tissue in "super-physiologic doses" of IL-1β for an extended period of time; and kept it isolated in petri dishes, which would not reflect what happens to a vulnerable infant in a "crisis situation." *Id.* at 186-87.

Similarly, Dr. McCusker opined that the Stoltenberg and Froen articles,[82] which reported that very young piglets did not recover from apnea as quickly when they received super-physiological doses of cytokines, had limited significance. *Id.* at 162-63. The articles reported this effect only in piglets younger than fifteen days old; in a previous study, cytokines did not have any effect on older piglets. *Id.* at 163. Dr. McCusker opined that pigs' and infants' respiratory systems develop at similar paces; therefore, piglets younger than fifteen days old could be compared only to infants under one month old. *Id.* at 164. Furthermore, she argued that Froen induced extremely high cytokine levels that would not occur naturally in infants. *Id.* at 171. On rebuttal, Dr. Miller responded to this criticism, by saying that pigs' *brains* are very different from human brains. Pigs are born with much more myelin than adult brains; they are much more mature than our brains. The piglets are walking and do things early in piglet life that humans take up to a year or more to do. Thus, this model is not an irrelevant model for a 4-month-old in terms of brain development. He noted correctly that what Stoltenberg and Froen were looking at was *brain physiolog*y or pathophysiology. They were not looking at respiratory development in terms of pulmonary or bronchial development or vascular or cardiac development. They were looking at the responsive neurons in the brain. Tr. 358.

Dr. McCusker also argued that studies of cytokine levels in human brains were only observational, and did not support Dr. Miller's theory. She stated that the Rognum article[83] found similar IL-6 levels in SIDS infants *with* and *without* minor infections. She argued that if infection upregulates cytokine levels, the data between these two groups should be different. *Id.* at 173-74.

Dr. McCusker opined that cytokines play a protective role. Specifically, they maintain homeostasis in the body. She stated that cytokines carry messages (e.g., that an infant's breathing is disrupted) to receptor cells, which contain gp130 molecules, which are supposed to respond to those messages (e.g., by prompting the infant to arouse or gasp). *Id.* at 174-77. Dr. McCusker noted that the Rognum article reported that SIDS brains showed increased binding of IL-6 to neurons in the arcuate nucleus, but no corresponding increase in expression of gp130 (a "signal transducer" for the 5-HT system).[84] She said that if the lack of a corresponding increase in gp130 is physiologically important, which "is a big if," it would imply that the increased IL-6 would not be doing anything. Tr. 175

[82] Stoltenberg et al. (1994), Exhibit 13-J; Froen, J.F. et al., *Adverse Effects of Nicotine and Interleukin-1β on Autoresuscitation After Apnea in Piglets: Implications for Sudden Infant Death Syndrome*, Pediatrics (April 2000), Exhibit 13-K.

[83] Rognum, Kinney et al. (2009), Exhibit 13-N; Kadhim et al. (2010), Exhibit 13-O.

[84] Rognum, Kinney et al. (2009), Exhibit 13-N.

As Dr. Miller mentioned, Rognum suggested that IL-6 may have "aberrant interactions" with the arcuate nucleus, leading to SIDS. However, Rognum also suggested another theory: that the "increased expression of the IL-6R in the arcuate nucleus *may be a compensatory mechanism* as defective arcuate neurons may require excessive IL-6 stimulation in order to respond to altered CO2 levels." *Id.* at 528 (emphasis added). Kinney cited this theory, writing: "The expression of IL-6 is elevated in the arcuate nucleus in SIDS infants, which may reflect a compensatory mechanism whereby defective arcuate 5-HT neurons require excessive cytokine stimulation to respond to infection-induced hypercapnia."[85] Dr. McCusker adopted and elaborated on this theory suggesting that IL-6 mounts a protective response. Tr. 157. She cited an article by Moidunny, which states that some IL-6 cytokines have "neuroprotective properties" and that IL-6 requires gp130 receptor subunits to be activated for signaling.[86] When a stressor – such as inadequate oxygen or hypoxia - occurs, the cytokines bind to the 5-HT system, which expresses gp130 molecules to prompt a response – such as prompting the body to turn over or gasp. Tr. 155-56, 161, 175-77, 241. Dr. McCusker opined that these responses can be "quite rapid, within hours or days." Tr. 180-81. Based on these findings, Dr. McCusker suggested that SIDS infants have potentially protective IL-6 molecules in the brain, but in SIDS infants hey fail to prompt the upregulation of gp130 molecules. Thus the IL-6 is ineffective. Tr. 176

Dr. McCusker stated that neither the Kinney team nor the AAP lists vaccinations as a risk factor for SIDS. *Id.* at 144. Dr. Miller testified to a conversation that he had with Dr. Kinney who told him that she did not want to study vaccines because she did not want to testify and did not want to be involved in vaccine controversies. Tr. 60. Dr. McCusker acknowledged that medical literature has reported a temporal association between vaccination and infant death in certain cases. Specifically, the Ottaviani study reported that a three-month-old white female infant received a hexavalent vaccine, lost consciousness one hour later, did not recover upon resuscitation, and passed away a few hours later.[87] Dr. McCusker highlighted that Ottaviani suggested the case might fall into a "SIDS 'gray zone'" because it was "difficult to establish whether the pathological findings [were] sufficiently severe to have caused the death." *Id.* Dr. McCusker noted that Ottaviani published another study of five infants displaying those same pathological abnormalities; however, that study did not mention vaccinations.[88] Therefore, she suggested that the vaccination in the first Ottaviani case was temporally associated with, but did not cause, that infant's death despite the fact that the author stated that in this case the sudden death in a child with arcuate hypoplasia could have been triggered by the hexavalent vaccine or could have been a gray zone case where it is difficult to determine if the pathological findings were sufficient to cause the death. Tr. at 103. It should be noted that the gray zone study focused on the neuropathology and histopathology of five specific SIDS victims to identify the possible brainstem abnormalities. The victims were chosen for study with no reference to vaccines or other specific causal pattern. The case report involving the child who died three

[85] Kinney et al. (2011), Exhibit 13-F at 195.

[88] Ottoviani G. et al., *Sudden Infant Death Syndrome "Gray Zone" Disclosed Only by a Study of the Brainstem on Serial Sections*, 33 J. Perinat. Med. 165 (2005), Exhibit C-16 at 6.

hours after receipt of the hexavalent vaccine was published subsequently to the gray zone study and mentions it as the group's prior work. It does hypothesize that the death could have been triggered by the vaccination or fall into the gray zone category.[89]

Dr. McCusker's comments in her report about the literature submitted by petitioners caused some concern, in that they could be read as misleading. Exhibit C at 7-8. Dr. McCusker stated that in the study by Rognum et al., "although [in SIDS infants] there was increased intensity staining for IL-6R, it was not different from those dying of infectious causes." Exhibit C at 7 (discussing Exhibit 13-N). However, Dr. McCusker did not note that at most the SIDS infants had mild infections, which would not be expected to cause elevated cytokines in the brain, while the other group had severe infections which *would* be expected to cause elevated cytokines in the brain and that "the mean IL-6R intensity grade in the arcuate nucleus was significantly higher in the SIDS group than in the control group."[90] [the control group died of "primarily violent causes."] *Id.* at 521.

Of greater concern was Dr. McCusker's characterization of the article by Kadhim et al. Exhibit C at 7-8 (discussing Exhibit 13-O). She stated: Kadhim et al. "examined IL-2 levels in SIDS versus non-SIDS brains and showed no difference in expression in IL-2 and they hypothesize that IL-2, like the cytokines IL-1β, TNFα, and IL-6, may be expressed in normally functioning brains of infants." Exhibit C at 7-8. Kadhim et al. actually stated; "SIDS victims often have preceding mild infectious/ inflammatory conditions (like coryza/ mild upper respiratory infections, soft stools/ mild gastroenteritis, post-vaccinal fever, etc.)"[91] They compared the brains of SIDS infants to those of infants who died of *severe* infectious/ inflammatory conditions. *Id.* at 123. They found that IL-2 levels were unexpectedly comparable in the two groups. *Id.* Kadhim said, "the comparable (equally intense) expression of IL-2 in SIDS infants was rather unexpected as SIDS victims have no obvious or detectable serious health conditions before death and that autopsies show no obvious cause for their demise. (as per definition). However, this high expression in SIDS would corroborate the tenet that SIDS victims experience hyperimmune reactions with 'exaggerated cytokine response to the often reported preceding mild/trivial infectious/inflammatory conditions. Upregulated cytokines exert serious effects on many biological systems including the turnover, release, and transmission of neurotransmitters; cytokines therefore act as neuro-modulators that could modify neural, neuroimmune, and neuroendocrine functions, and can modify synaptic transmissions." *Id.* at 125. The authors further concluded, "Thus various biological stressors such as infectious inflammatory, ischemic or anoxic, and hyperimmune conditions, and metabolic disorders induce IL-2 which is preferentially expressed in vital brainstem neuronal centers. IL-2 and other subsequently triggered cytokines in downstream immune inflammatory mediators interact with neurotransmitters and/or their receptors and modify their function. The resulting neuronal molecular disequilibrium tips the delicate molecular balance causing dysfunction in those vital

[89] Ottoviani et al. (2006), Exhibit 13-T at 103.

[90] Rognum, Kinney et al. (2009), Exhibit 13-N at 521.

[91] Kadhim et al. (2010), Exhibit 13-O at 122.

brainstem centers in producing disturbed homeostasis with potentially drastic effects on target organs systems and eventual death." *Id.*

Dr. McCusker reviewed the epidemiological papers submitted and noted that an article by Kuhnert found a *decreased* incidence of SIDS in days 1-3 after vaccination, then *increased* incidences of SIDS in days 4-7, 8-14, and 15-21. Tr. 229-35.[92] Furthermore, she stated that other studies did not find *any* temporal association between vaccination and SIDS. First, an article by Jonville-Bera et al. did not find a heightened risk of SIDS in French infants vaccinated at three months old.[93] Second, Toro et al. found that the incidence of SIDS in two-month-old children in Hungary decreased when that country instituted vaccinations at that age. *Id.* at 7.[94] Third, Vennemann et al. did not find an increased risk of SIDS with vaccination.[95] In Dr. McCusker's opinion, "large studies, designed to unmask rare events, have shown no link between vaccination and SIDS and have at least in some studies demonstrated a vaccine protective effect for SIDS." Exhibit C at 7.

At trial, Dr. McCusker added that the Kries study cited by petitioners did not support their case. Specifically, SIDS is defined as a syndrome that only affects children "under one year of age."[96] However, Kries et al. did not find an association between vaccination and death in children under one year old. They found an increased incidence of SIDS only in children vaccinated during the *second* year of life. *Id.* Therefore, she said this study does not support petitioners' theory about vaccination and SIDS. Tr. at 257.

ii. *Althen* Prong Two: Response to Petitioners' Opinion of a Logical Sequence of Cause and Effect

Dr. McCusker stated that there was "no evidence" that vaccinations contributed to J.B.'s death from SIDS on September 3, 2011. Exhibit C at 8; Tr. 126. She did not dispute that J.B. was in the critical development period. She agreed that "according to the triple-risk theory, the brain problem must exist" for an infant to succumb to SIDS. Tr. 206.

She agreed that vaccines "increase cytokine circulation." Tr. 195. She also stated that Kashiwagi et al. showed that 24-48 hours after vaccination, a child will have elevated cytokines, whether or not he has a fever. Tr. 199. "Cytokine elevation in this model is independent of fever." *Id.* Dr. McCusker stated that J.B. had a fever, and because he was generally healthy and had no signs of upper respiratory infection, the fever could be attributed only to his vaccinations. Tr. 204-05. The fever was "an indication that [J.B.] was responding… to the vaccine." Tr. 238.

---

[92] Kuhnert et al. (2012), Exhibit C-20.

[93] Jonville-Bera A., et al., *Sudden Unexpected Death in Infants Under 3 Months of Age and Vaccination Status – A Case Control Study*, 51 Br. J. Clin. Pharmacol. 271 (2001), Exhibit C-18.

[94] Toro K. et al., *Change in Immunization Schedule and Sudden Infant Death Syndrome in Hungary*, 42 FEMS Immunol. and Med. Microbiol. 119 (2004), Exhibit C-19.

[95] Vennemann et al. (2007), Exhibit C-17.

[96] Kries et al. (2005), Exhibit 13-R at 1.

She stated that J.B. had a fever on September 3, 2011, but after he was given Advil that morning at approximately 8:00 a.m., his fever resolved. Exhibit C at 4; Tr. 204-05, 237. She also stated that a non-steroidal would last for eight hours. Tr. 192. She stated that "if IL-1β mediated respiratory depression [occurred] in the case of J.B., the Advil he was given would have acted to counter this effect, suggesting that this mechanism was not involved in his death from SIDS." Exhibit C at 5, 8.

Her theory was that J.B. 'was put down for his nap, he rolled over, he started rebreathing, and he died of a sudden infant death due to hypercapnia… independent of any cytokines." Tr. 206. She opined that there were several recognized exogenous stressors in J.B.'s case: formula feeding, side sleeping, soft bedding, and a pillow under his head. Exhibit C at 5; *also* Tr. 128-29. In her report, Dr. McCusker stated that J.B. "was found on his side with his face down on a pillow." Exhibit C at 4 (citing Exhibit 7 at 6). (The sixth page of this exhibit is a confirmation of faxing the record.) However, the preceding page is a handwritten scene investigation form. It states that J.B.'s crib had a "little crib pillow." Exhibit 7 at 5. J.B. was found "on side with head downward." *Id.* The form also indicates that neither J.B.'s nose nor his mouth was covered. *Id.*

At the hearing, Dr. McCusker first testified that J.B.'s "face was downward according to the reports." Tr. 128. On cross-examination, she could not identify where in the record it said that his face was down on a pillow. Tr. 265. She thought "he was found with his head down. There was a pillow in the bed, which is clear from the photos. So, it would be easy to hypothesize that he was at least found face down in the general vicinity of a pillow, and one would wonder what the pillow was doing in the bed if it wasn't for under his head." Tr. 266. She noted that the photos of the crib showed a pillow on one end of the bed and diapers and wipes on the other end. Tr. 266 (discussing Exhibit 9 at 8-9). She opined that J.B.'s head would have been on the end of the bed where the pillow was. Tr. 266-67. Dr. McCusker acknowledged, however, that she did not know whether J.B. was actually found with his head on the pillow. Tr. 267. She also agreed that J.B.'s crib was taken down shortly after his death, after which law enforcement and J.B.'s parents participated in a death scene reenactment. Tr. 267-68. That reenactment does not mention the pillow or any other elements that were in the crib. Tr. 268.

The undersigned asked Dr. McCusker about the "mechanical effect" of the sleep position she assumed that J.B. was found in. Tr. 269. Dr. McCusker stated that side-sleeping, a pillow under the head, "the lack of tight bed sheets," and the "disarray" in the crib all together present "the same risk factors as prone" sleeping. Tr. 269-72. The undersigned commented that these facts were not completely clear from the record. Tr. 272.

iii. *Althen* Prong Three: Response to Petitioners' Timing Argument

Dr. McCusker stated that she understood Dr. Miller's testimony to be that "the upregulation of the serotonin through the TPH2 and 1433 system… would not be an instantaneous event and that it would take time and presumably more than 24 hours' time." Tr. 180. She stated that "the production of increasing cortisol that occurs following a stimulus and

upregulation through IL-6 is actually quite rapid, within hours, not days." Tr. 181.[97] But she also stated that Kashiwagi et al. showed that a child will have elevated cytokine levels in the blood 24-48 hours after vaccination. Tr. 198.

3. Respondent's Expert Dr. Brent Harris

Dr. Brent A. Harris earned a Masters in Biology from Hahnemann University in 1988. Exhibit A at 1. He then earned a M.D. and a Ph.D. in Pharmacology from Georgetown University in 1995. *Id.* He then obtained post-doctoral training at Stanford Medical School, where he was a resident in Anatomic Pathology from 1995-1999, chief resident from 1997-1998, and a neuropathology fellow from 1997-1999. *Id.* Dr. Harris is board certified in anatomic pathology and neuropathology and is a Fellow of the College of American Pathologists. *Id.* He is currently an Attending Pathologist, Associate Professor in Neurology and Pathology, and Director of Neuropathology at Georgetown University Medical Center. *Id.* He also serves as a Neuropathology Consultant for the Chief Medical Examiner, the National Institutes of Health, Howard University Hospital, the Washington, DC Veterans Administration Hospital, and the American International Pathology Laboratory. *Id.*

i. *Althen* Prong One: Response to Petitioners' Theory

Dr. Harris agreed with the other experts that the Triple Risk Model is a generally accepted and reliable model of SIDS. Tr. 345. He could not say whether all extrinsic risk factors are mechanical or whether some of them may be neurochemical. *Id.* at 346. However, he testified that he would want to see conclusive proof before he would list vaccines as a risk factor in a medical report that he wrote. Tr. 348. He was aware of studies finding that vaccinations induce the production of cytokines in the brain, but not of any studies finding that those cytokines have a detrimental effect. Exhibit A at 6.

ii. *Althen* Prong Two: Response to Petitioners' Opinion of a Logical Sequence of Cause and Effect

Dr. Harris agreed with the characterization of J.B.'s death as SIDS and that under the Triple Risk Model, J.B. was in the critical development period. Exhibit A at 6. It cannot be confirmed whether J.B. had a brain defect rendering him "vulnerable" because the autopsy did not sample that section of the brain. Exhibit A at 6.

Dr. Harris opined that if vaccinations are found to be an exogenous stressor, they "certainly cannot be proven in J.B.'s death." Exhibit A at 6. He stated that there were "no pathologic findings in the brain or other organs in this case that indicate a vaccine-related death." Exhibit A at 7; *see also* Tr. 328. J.B.'s brain was found to have metabolic glia, which are not fully understood. Exhibit A at 6-7. Dr. Harris also opined: Induction of cytokines after

[97] This may not be an accurate characterization of Dr. Miller's opinion. A review of the transcript did not find a clear statement from Dr. Miller about the timing of cytokine production. But in his expert report, Dr. Miller actually opined that cytokine production would *begin* "within hours" and would *peak* "within 2 to at most 4 days." *See* section above (citing Exhibit 16 at 1).

vaccination is a recognized physiological response involved in the immune process. The primary immune surveillance cells in the brain are microglia.These cells when activated by circulating molecules or direct invasion in the brain by organisms change their morphology and produce a host of cytokines in response. Over-activation of these cells in J.B.'s brain is a non-specific finding that could be related to the prior day's vaccination and/ or infection." Exhibit A at 6. Dr. Harris testified that the "circulating molecules" that activate microglia can be either lipopolysaccharides from bacteria or "circulating cytokines," although this is not completely understood. Tr. 342.

iii. *Althen* Prong Three: Response to Petitioners' Timing Argument

Dr. Harris agreed with Dr. McCusker's opinion that cytokine signaling "doesn't happen immediately but happens over a period of time." Tr. 343. He did not otherwise address the timing for the cytokine response or whether it fit the case of J.B.

III. ANALYSIS

A. Summary of the Arguments

The parties agree that the sole issue to be resolved is "whether the vaccines that J.B. received on September 2, 2011 caused or substantially contributed to his death." Joint Prehearing Submission at 2. Pursuant to *Althen,* petitioners must show by a preponderance of the evidence a reasonable theory as to how the vaccine could cause the harm at issue, a logical but not scientifically certain explanation of how it did, and show the timing was appropriate given the theory of causation. The Federal Circuit has observed that this preponderance standard enables "the finding of causation in a field bereft of complete and direct proof of how the vaccines affect the human body." *Althen v. Sec'y of Health & Human Servs.,* 418 F.3d 1274, 1280 (Fed. Cir. 2005). The standard permits the use of "circumstantial evidence" and accomplishes Congress's goal that "close calls regarding causation are resolved in favor of injured claimants." *Id.* (citing *Knudsen v. Sec'y of Health & Human Servs.*, 35 F.3d 543, 549 (Fed. Cir. 1994) ("to require identification and proof of specific biological mechanisms would be inconsistent with the purpose and nature of the vaccine compensation program")).

To address the issue in the case, several questions must be addressed. The specific questions for decision are whether inflammatory cytokines generated by a mild infection are likely the critical exogenous stressor in many cases of SIDS when mild infection is also present. The second question is whether the same cytokines are stimulated by the innate immune response to vaccines and whether they are likely to be the exogenous stressor in some SIDS cases, particularly, as in this case, when the child was thoroughly examined by a physician the day before he died and found to be completely healthy, and there was no evidence of viral infection by nasal swab at autopsy.

Petitioners' theory is essentially that a high percentage of SIDS infants, almost 50% in most studies, have no history of a serious illness in the days and weeks prior to death, but have a mild infection or fever at the time of death. In most instances, the mild infection was an upper

respiratory infection, although one author listed post-vaccinal fever among the conditions.[98] In this case, J.B., a nearly five-month-old African American boy, who had been born at 36 weeks, died of unknown causes while napping in the early afternoon one day after receiving his scheduled four-month vaccines. He had a well-documented physical examination the prior day, performed by an M.D. pediatrician who had performed a similar examination about five weeks prior. J.B. was documented to be healthy, with no signs or symptoms of illness. He had patent nasal passages and clear lungs, and he was progressing well in terms of growth and milestones. His pediatrician noted that he was able to raise his head, hold it steady and roll over. In the 28-hour period following vaccination, at 4 a.m. and again at 8 a.m., his mother noticed that he had a mild fever and gave him children's Advil. He seemed to be fine and playing normally during the morning, but was fussy and started running a fever again in the early afternoon. Exhibit 8 at 2. His father then put him in his crib for a nap. He was put in the crib on his back, with a blanket over his midsection. He was using a pacifier. There was a small, flat, crib pillow in the bed. The air conditioning in the house was set at 76 degrees. His mother checked on him and replaced his pacifier during his nap. She came back about ten minutes later, noticed that he had rolled onto his side with his head tilted slightly downward, and he was not breathing. There is no evidence that his breathing passages were in any way obstructed or that his face was down in the bed or pillow when his mother found him. She called 911. Police and emergency medical personnel responded within minutes. J.B. was transported to the hospital when he could not be revived on scene. He was pronounced dead at the hospital.

Under the first leg of the Triple Risk Model, petitioners theorize that J.B. likely had a defective or under-developed serotonin system in the arcuate nucleus or other medullary area, which unfortunately was not examined or sectioned at autopsy. He was clearly within the vulnerable risk period for SIDS in that he was between four and five months old and, given his pre-maturity, only about four months based on dates of conception. He had several intrinsic risk factors in that he was born at 36 weeks, he was male and he was African American, all of which groups are overrepresented among SIDS deaths – blacks more than whites and Hispanics, boys more than girls, and preterm babies more than term babies. As noted above, at birth, J.B. had Apgar scores of 8 at one minute and 9 at five minutes. He had grown to 16 pounds and was well within the average ranges for height, weight and head circumference. He appeared to be meeting expected milestones as documented by his pediatrician. He was receiving good medical care and did not appear to be affected by issues associated with poverty, which is often speculated to account for the overrepresentation of African American babies in the SIDS statistics. He was a boy and it has been suggested, as noted above, that boys are more dependent than girls on an effective serotonin system for sensing the accumulation of carbon dioxide and responding appropriately to clear it.

Also, J.B. was put to bed on his back. At J.B.'s two last appointments, Dr. Wright noted that he slept on his back. The available evidence indicates that he rolled onto his side but was not prone. His mother described in the police reenactment that he had turned to his right side and his head was turned slightly downward. Nothing in the notes of the reenactment indicated that the baby's mouth or nose were in or close to the bedding, and in her police interview his mother noted that his nose and mouth were not covered. His father indicated that he had a fever when he was put down for his nap.

[98] Kadhim et al. (2010), Exhibit 13-O at 122.

Thus, petitioners theorize that he did have a fever during the night, early morning and before his nap. Dr. Miller testified that the fever documents the effect of inflammatory cytokines, likely IL-1 and/or IL-6 signaling from the periphery to the hypothalamus to cause the fever. They also theorize that the fever elevates body temperature, which is another risk factor for SIDS. According to petitioners' theory, because J.B. had no evidence of illness or infection prior to vaccination, it is therefore highly likely that the fever was generated by the vaccines, which likely caused a cascade of cytokines to cross the blood brain barrier and further suppress the function of the already underdeveloped medullary serotonin system during sleep. This caused his death to occur within about 28 hours of the administration of the four-month vaccines.

Respondent disagrees, saying that J.B. was premature, an African American boy, and was side sleeping, all of which are risk factors for SIDS. Citing the principle of Occam's Razor, he argues that it is unnecessary to consider anything beside these known risk factors and that the proximate timing to the administration of the vaccines can be explained by coincidence given that the peak time period of the occurrence of SIDS deaths coincides with the timing of the two month and four month vaccine administration schedules. He further argues that there has not been epidemiology to substantiate a causal relationship between vaccines and SIDS. Dr. McCusker argued that the role of mild infection in relation to SIDS deaths is one of obstructing airways rather than one of chemosensitivity, and she discussed her experience of suctioning the noses of infants brought into the emergency room with upper respiratory infections.

Dr. Miller and Dr. Harris agreed that an ideal autopsy would have sectioned the ventral medulla and that that was not done in this case. They also agreed that the type of histological examination that was done by Dr. Kinney and others would be unlikely to be done in a standard autopsy. Tr. 339. They agreed that there is not definitive proof of defective medullary structures.

B. *Althen* Prong One

After extensive review of the literature in the field of SIDS causation and listening to the testimony of the experts in this case, I think it is clear that the Triple Risk Model is broadly accepted as the general structure for understanding SIDS, even if the lack of comprehensive autopsies do not allow the medical profession to say that SIDS always has a deficient medullary serotonin system, as demonstrated in up to 75% of the cases examined by Dr. Kinney and her group.[99] She has said that "the most compelling hypothesis is that SIDS is related to a brainstem abnormality in the neuroregulation of cardiorespiratory control."[100] She further observed, "according to the Triple Risk Model, *only* infants with an underlying brainstem disease process die of SIDS, which explains why all infants who are placed prone to sleep or who bed share do not die of SIDS. They do not have the underlying vulnerability." *Id.* at 521. Dr. Miller opined that it is likely that J.B. had this defect based on the data from these studies. Tr. 37. Dr. McCusker agreed, "according to the triple-risk theory that the brain problem must exist." Tr. 206. The "brain problem" described in the triple-risk literature is that in the respiratory control center in the medulla. As such, it is reasonable to conclude that the petitioners have shown by a

[99] Kinney & Thach (2009), Exhibit A-4 at 6.

[100] Kinney et al. (2009), Exhibit 13-H at 519.

preponderance of the evidence that an infant who has died of unknown causes, and in whom autopsy has ruled out other causes, had the inherent brainstem vulnerability. I do conclude that J.B. did.

There is also no disagreement that the Back to Sleep Campaign convincingly demonstrated the danger of prone sleeping. By persuading parents to place babies on their backs to sleep during the vulnerable risk period, the campaign brought about an approximate 50% reduction in the rate of SIDS. Side-sleeping has also been recognized as having an elevated relative risk for SIDS, but the reason for this is not entirely clear. Dr. McCusker stated at some length her understanding of the mechanics of breathing in an infant. Essentially, she explained that the diaphragm drops down creating negative pressure within the lung relative to the atmosphere, at which point air rushes in. She suggested that the stomach muscles which the baby uses to help drop the diaphragm are compressed, as are the soft ribs in infants who are prone or side-sleeping, which reduces the gas exchange. Tr. 129-32. Dr. Miller disagreed with her explanation of respiratory physiology in that he did not find persuasive the notion that side-sleeping in a four-month-old is going to inhibit the ability to have inspiratory motion in the diaphragm, which creates the negative pressure in the lungs. Rather, he said the literature in SIDS has emphasized the pocket of air and re-inhaled carbon dioxide. Tr. 354.

The policy statement by the American Academy of Pediatrics, which was repeatedly referenced by Dr. McCusker but not marked as an exhibit, says that the risk of side-sleeping is similar in magnitude to prone sleeping (2.0 vs. 2.6).[101] The statement appears to focus on the risk of turning if the infant is placed on his side. "The risk of SIDS is exceptionally high for infants who are placed on their sides and found on their stomach. The side sleep position is inherently unstable, and the probability of an infant rolling to the prone position from the side sleep position is significantly greater than rolling prone from the back." *Id.* at 7. Interestingly , the same report addresses the issue of children who are able to roll over, which it notes generally occurs at 4-to-6 months of age, and that as they age it is more likely that they will roll. The Academy recommends, "If the infant can roll from supine to prone and from prone to supine, the infant can then be allowed to remain in the sleep position that he or she assumes." *Id.* at 8.

In this case, J.B. was placed supine and he rolled to his side, but not prone. It would appear from this policy statement that the greatest concern with side sleeping is when the infant is placed on its side and can easily roll to the prone position. The fact that the Academy recommends allowing the baby to remain in the position to which he rolls after being placed supine suggests that it is likely that a baby who can roll probably also has developed the ability to raise and turn his head.

All of the experts in this case appeared to agree that at least the predominant thinking in medicine as to the cause of SIDS is explained by the Triple Risk Model. Although as Dr. Harris testified we do not know with certainty that the medullary serotonergic network deficiency is always present because a great many autopsies, such as the one in this case, are not adequate to

[101] Moon R.Y. et al., American Academy of Pediatrics – Task Force on Sudden Infant Death Syndrome, *SIDS and Other Sleep Related Infant Deaths: Expansion of Recommendations for a Safe Infant Sleeping Environment,* 128 Pediatrics 1030 (2011), available at http://pediatrics.aappublications.org/content/128/5/1030.long.

document that deficiency, it was also recognized that as Dr. Kinney stated in a 2009 paper, "only infants with an underlying brainstem disease process die of SIDS."[102] Dr. McCusker agreed that according to the triple risk theory the brain problem must exist. Tr. 206. There has also not been significant debate about the statistical relevance of the other intrinsic risk factors. The success of the Back to Sleep Campaign in educating the public about the danger of prone sleeping has been remarkable in reducing SIDS deaths by half. But the other half still occur. The question remains as to what extrinsic risk factors come to play at that "fatal intersection of vulnerability, critical period and stressor."[103] The literature strongly suggests that SIDS is likely to be multi-factorial. Some cases are likely to be caused by continued prone sleeping, but others are likely caused by other factors. Mild infections, often described as "trivial" infections, appear to be a factor as they have been reported to be present in nearly 50% of SIDS deaths, raising the question of what it is about mild, otherwise non-life threatening infections that appear to interact with the impaired medullary serotonin system during the vulnerable period to cause the "perfect storm" that results in an unexplained death of a child?

Dr. Miller, relying on multiple pieces of research described in the SIDS literature, opined that it is likely that the cytokine signaling triggered in the immune system by mild infection interacts with the underdeveloped 5-HT system in the brainstem, during sleep when the excitatory function of serotonin is reduced, to further suppress the function of the brainstem to cause a cardio-respiratory crisis. The further issue raised is whether, in the absence of a mild infection, can the multiple vaccines administered together – in this case the day before – trigger the same cytokines as does a mild infection with the same fatal result? Dr. Miller concluded that they do.

Petitioners refer to the significant number of SIDS deaths that document the co-occurrence of mild or trivial infections which appear to stimulate a cytokine response similar to that generated by severe infections with adverse or repressive effects on the 5-HT system for chemosensitive response to hypercarbia, leading to failure to arouse and failure to initiate a gasping reflex and ultimately death. Petitioners are not the first to suggest this theory. Dr. Kinney has written, "A causal role for mild infection in sudden infant death is suggested by reports that in approximately half of SIDS cases, the infants have a seemingly trivial infection around the time of death, as well as mild tracheobronchial inflammation and altered serum immunoglobulin or cytokine levels and the presence of microbial isolates at autopsy. In infants who die unexpectedly of infection, the given organism may precipitate *a lethal cytokine cascade or toxic response*."[104] Another article by her group explained the likely mechanism: "During infection, peripherally produced IL-6 may cross the blood brain barrier and bind to IL-6 receptors on 5-HT neurons that mediate homeostasis in response to the infectious stressor and potentially mediate sickness behavior. …We found ubiquitous expression of IL-6 receptors and gp130 neurons in all regions in the infant medulla, including those effector nuclei critical to respiratory and autonomic control, and those that contain 5-HT source neurons. Serotonergic

neurons in the caudal 5-HT system, including in the raphe obscurus and arcuate nucleus, express IL-6Rs on somata and processes, indicating the site of IL-6/5 HT interaction."[105]

Various authors have identified the presence of IL-1β, IL-6, and IL-2, which are all pro-inflammatory cytokines, in elevated levels in the infant medulla in SIDS. Stoltenberg studied the effects of injection of IL-1β in piglets, and theorizes that in addition to cytokines being transported to the brain by retrograde axonal transport, his findings suggested an equally important alternative route in the immune-stimulation of the brain, inducing hypoxia and sudden infant death. He said that it has been shown that IL-1β is internalized by blood brain barrier endothelial cells, which implies that this cytokine passes through the blood brain barrier at the endothelial rather than the ependymal or blood cerebrospinal fluid part of the brain barrier. He found in his experiments with piglets that IL-1 stimulates the release of β-endorphin and the level of β-endorphin in CSF correlates strongly with the duration of apnea. Further, he found that "IL-1β stimulates GABA-transmission and hence increases the inhibitory postsynaptic function by opening of chloride-delective channels, and this will reduce the activity in the central respiratory neurons and may produce hypoxia."[106] Dr. McCusker referred to an article by Besedovsky for the proposition that cytokines are produced in the brain, suggesting that cytokines active in the brain necessarily originate in the brain. However, on review of the article, Besedovsky also noted that some cytokines such as IL-1 and IL-6 are produced both peripherally and within the brain.[107] He postulated that tripartite synapses possess the cellular and molecular components to function as a "relay system" capable of receiving and integrating peripheral immune signals with central neural signals. *Id.* at 5.

One of the best understood functions of cytokines in the case of infection and vaccination is the triggering of fever. When this occurs, cytokines from the periphery at the site of the infection travel to the brain, in particular to the hypothalamus, which then causes fever. As J.B. had a fever in the day following vaccination after having a completely clear medical examination the day before, Dr. McCusker agreed with Dr. Miller that in order for fever to have occurred there had to be a hypothalamic signal, which is mediated by endogenous pyrogens, i.e. IL-6 or TNFα. Tr. 286. The literature also recognizes IL-1 and others which are known pyrogens as well. She also agreed that in the absence of an infection, the only thing we can attribute the fever to is the vaccine. Tr. 205.

After identifying a plausible mechanism for the means of activation of cytokines in the medullary brainstem from a peripheral source, the next key question is why does mild or trivial infection appear to occur in conjunction with SIDS? It is not the infection itself which causes death, as by its mild nature it is not life threatening. Whether the infection is mild or severe, it triggers the innate immune response, which in turn triggers the release of cytokines. As Dr. McCusker explained, cytokines are small molecules that are released by different cell types originally described in immune cells. They are viewed primarily as communication molecules,

because they are released by one cell and bind to another through a series of signaling steps. Tr. 145. Dr. Miller explained that cytokines are messenger molecules that have a lot of different effects which were first identified as products of the innate immune system, but are seen elsewhere as well, including the brain. IL-6 binds with 5-HT and IL-1 has been shown in animals to inhibit 5-HT firing. Tr. 30. There was no disagreement between the experts or in the literature that cytokines are released by the innate immune response to infection, whether it be mild or severe.

The Siljehav-Hofstetter article filed by respondent provides an additional theoretical basis for the role of cytokines in SIDS. The authors found that IL-1β stimulates a prostaglandin (PGE2) with receptors in the rostral ventrolateral medulla. They explained that once stimulated by IL-1β, PGE2 induced depression of this vital brainstem neuronal network, e.g., during an infectious response, that could result in gasping and autoresuscitation failure and ultimately death."[108]

Dr. Miller found further support in the work of Kadhim, who found overexpression of IL-1β in the arcuate nuclei in 17 of 17 SIDS brains studied, but only in 1 of 6 non-SIDS brains.[109] Kadhim noted that cytokines could exert neuromodulatory effects in the ascending reticular activating system, which is involved in the arousal reflex. He noted that IL-1 causes prolonged apneas and depresses respiration and the brain appears to be less effective than the periphery in inducing IL-1 antagonist to terminate IL-1β actions. He hypothesized that the particular pattern of neuronal cytokine he detected might therefore overturn a subtle equilibrium in a molecular chain involving vital brain centers, causing SIDS. *Id.* at 1259.

In a second study involving SIDS brains, Kadhim's group noted that SIDS victims often have preceding mild infections and that cytokines have neuromodulatory effects whereby they can modify neurotransmission. In this study, they compared the brainstems of SIDS victims to those of infants who died of diverse severe pathological conditions, mainly infectious, hemodynamic, metabolic, severe congenital, or other serious conditions. They found that IL-2, another inflammatory cytokine, was preferentially expressed in specific neuronal centers within the brainstem. In this study, they found equally intense immune reactivity within the arcuate and dorsal vagal nuclei in fatally sick infants, as with SIDS victims who had no obvious or detectable serious health condition before death. They hypothesized that a hyperimmune response to mild infection in the SIDS babies may result in a molecular disequilibrium which tips the delicate molecular balance, causing dysfunction in those vital brainstem centers and producing disturbed homeostasis with potentially drastic effects on target organs/systems and eventual death.[110]

[108] Siljehav (2012), Exhibit C-9 at 9897.

[109] Kadhim et al. (2003), Exhibit 13-L at 1256.

[110] Kadhim et al. (2010), Exhibit 13-O at 122-26.

Brambilla also provided some support for this theory by demonstrating in animals that IL-1 inhibited firing of neurons that promoted wakefulness in the dorsal raphe nucleus and enhanced activity of GABAergic neurons which are inhibitory and induce enhancement of NREM sleep.[111]

Rognum further compared brains of SIDS victims to those of babies who died of severe infections and to another group who died from drowning, suffocation, strangulation, or other violent causes. They found that the SIDS babies had higher cytokines in the medullary brainstem than did those who died of violent causes but their levels were not as high as those that died of infectious causes. In a small section of their study, the Rognum group found elevations of IL-6R in the arcuate nucleus in the SIDS and infection groups relative to the controls. However, they found that the gp130, which is necessary for IL-6 to function, did not rise as high above the controls as did the infection group, although it was higher than in those dying violent deaths. This caused them to speculate that the IL-6R might be reactive to an excess carbon dioxide crisis rather than its cause. Thus significant evidence has been produced to show that cytokines are abundantly present in the medullary brainstem of SIDS infants relative to those dying of other causes which strongly suggests a hyperimmune response to mild infection in these children well out of proportion to the mild or trivial infection that they had. The presence of these cytokines also appears likely to suppress the 5-HT response to the accumulate of carbon dioxide in the body and the ultimate failure of the respiratory response system.

The next important question is whether the vaccines can play the same cytokine generating role as mild infection in a child who does not have an infection. If, as his father described, the child developed symptoms such as a fever, crankiness and not being himself, signs of cytokine activation, and had no evidence of infection, could one or more of the seven vaccines he received the day before have generated a cytokine cascade that caused him to be unable to respond to elevated carbon dioxide in his system, whether it was produced by rebreathing or metabolically? Dr. Miller's thesis was that the main role for mild inflammation as a risk factor for SIDS is thought to be in elevating cytokines. He said that is explicit in multiple articles that have been submitted. Then, if vaccines produce the same cytokine responses as very mild upper respiratory infections, which is what is demonstrated by Kashiwagi, it would seem logical to impute both having the same effect on the central nervous system. Tr. 370.

Indeed, Kashiwagi conducted testing with multiple vaccines and studied the cytokine response. He found that there was a more significant response in children who received three or four vaccines at one time than in those who received fewer, and he found that higher IL-1β production was noted in young infants, but decreased at around 2 years or older.[112]

He also examined the cytokine profiles in 61 serum samples obtained from recipients who exhibited febrile illness within 24 hours of being vaccinated and 18 serum samples from recipients without febrile illness. The samples were taken within 48 hours of vaccination in both groups. These were compared to each other and to cytokine profiles of ten normal subjects

[111] Kinney et al. (2009), Exhibit 13-H.

[112] Kashiwagi et al. (2014), Exhibit 17 at 680.

without vaccination. "Higher levels of IL-6, IL-10, IL-12, G-CSF,[113] and IFN-α were detected in both the febrile and non-febrile vaccination subjects in comparison with those in normal subjects." *Id.* at 680.

The Lee and Schulzke studies of multiple vaccine administration to premature infants, referenced above, found an elevation in the rate of apnea, bradycardia, and, in the Lee study, oxygen desaturations (Schulzke did not look at desaturations). Both authors hypothesized that the adverse events may be related to the immune response to the vaccines, particularly as Lee found there was no difference in the rate of adverse events between whole cell pertussis and acellular pertussis.[114] Schulzke noted that the adverse events occurred within 6 to 24 hours of vaccination.[115] While not studying SIDS, these studies focused on premature infants in a controlled environment – a hospital – where the mechanism that is hypothesized to occur in SIDS could be rapidly recognized, addressed, and treated. It seems quite likely that the same sequence occurring post-administration of multiple vaccines may be what occurs in the uncontrolled environment of the home when the child and often the parents are sleeping, or at least not in the same room with the child when the combination of events leading to the fatal sequence occurs.

Dr. Miller's theory, consistent with many of the articles in the literature, is that SIDS is multifactorial. Multiple factors come together at the fatal moment that causes the perfect storm leading to death. He theorizes that the cytokines triggered by the vaccines in the initial innate immune response to the vaccines travel to their receptors in the arcuate nucleus and suppress the serotonin function in a child whose functionality in that area is already impaired by an underdeveloped or defective 5-HT system while he is asleep, which further reduces 5-HT function. The input of the cytokines stimulated by the vaccines causes the lack of response to elevation of carbon dioxide that converts a recoverable event to a fatal one. Whether the vaccine generated cytokines cause additional metabolic activity generating fever and additional production of carbon dioxide, or whether they caused the neurons in the brainstem to be unable to respond to rebreathed or accumulated carbon dioxide, it is probable that they played an important role in causing the death of this infant.

Dr. McCusker disagreed. She argued that the presence of the various intrinsic risk factors together with a flat pillow in the bed and side-sleeping to which the child turned after being placed supine was sufficient to explain the death. She argued that the role of mild infection was that it caused obstruction in the nasal passages in infants who are "obligate nose breathers" (Tr. 138) and mucous in the nose would obstruct the breathing of the child sufficient to cause death. She referred to infants she sees in the emergency room with upper respiratory tract infections who need to be suctioned which then brings down their carbon dioxide level. Tr. 139-40. Dr. Miller disagreed. He stated that he had never seen a SIDS autopsy where the death was

---

[113] G-CSF is an abbreviation for granulocyte colony stimulating factor. It is another cytokine which mobilizes and recruits neutrophils to the site of inflammation from the marginal pool. Kashiwagi et al. (2014), Exhibit 17 at 693.

[114] Lee, J. et al., *Frequency of Apnea, Bradycardia, and Desaturations Following First Diphtheria-Tetanus-Pertussis-Inactivated Polio-Haemophilus Influenzae Type B Immunization in Hospitalized Preterm Infants*, 6 BMC Pediatr. 20 (2006), Exhibit 20.

[115] Schulzke (2005), Exhibit 21 at 3.

attributed to nasal passage obstruction by mucous and that he had never seen any literature to support that concept. Tr. 355.

The literature certainly suggests that Dr. McCusker's interpretation of the role of mild infection was too limited in that she ignored the entire concept of brainstem chemosensitivity in response to carbon dioxide accumulation. Dr. Kinney wrote, "Serotonergic neurons at the medullary ventral surface and in the midline (raphe) are now known to be preferentially chemosensitive to CO2 and although they are not the only central chemosensitive neurons they appear to play a critical potentially modulatory role. … A small but important population of 5 HTE neurons is embedded within the human arcuate nucleus suggesting that the putative dysfunction in chemosensitivity related to the arcuate anomaly specifically involved these embedded 5 HT neurons."[116] In an article in the New England Journal of Medicine, Kinney wrote, "the arousal from sleep that is triggered by abnormal levels of carbon dioxide and oxygen is essential for the initiation of protective airway responses. … Arousal involves a progressive activation of specific subcortical to cortical brain structures and consists of ascending and descending components that mediate cortical and subcortical arousal respectively."[117] The importance of the chemosensitive role in the stimulation of breathing, arousal, and ultimately gasping in response to the accumulation of excess carbon dioxide appears critical to all of the triple risk hypotheses. A stuffy nose does not explain the inability of the neurons in the arcuate nucleus to modulate breathing rhythm and respond to excess carbon dioxide by initiating breathing, particularly when there was no evidence of mucous congestion in the nose the day before at the medical exam, in the report of the parents, or at the autopsy. The role of cytokines stimulated by vaccines administered approximately 28 hours before seems much more likely to play a critical role, similar to that of mild infection in causing the ultimate convergence of the multiple factors leading to death. The inhibition of the 5-HT response, beyond its initially impaired level with which the child had lived to that date, seems more likely to be caused by the cytokine response to the multiple vaccines than to a stuffy nose or the side-sleeping position to which he had turned, particularly when there was no evidence of nasal congestion or of the breathing passages being obstructed. Exhibit 7 at 5. In fact the evidence was to the contrary.

Dr. McCusker, citing to the Imeri article[118] on sleep in general, also testified that fever would tend to push the child out of REM sleep and into NREM, which she argued would make him more arousable. A review of the Imeri article, which discusses the immune system and sleep in general, and not specifically in infants, does indeed discuss the role of fever and the generation of shivering in NREM sleep and that during the course of most infections there is an increase in the amount of time spent in NREM sleep and a decrease in the amount of REM sleep. *Id.* However, it also discusses the role of IL-1 and the generation of GABAergic inhibitory cytokines. *Id.* at 205. Imeri also acknowledged the role of peripherally generated cytokines in the regulation of sleep. Imeri concluded that at present we know little about these mechanisms

by which cytokines inhibit REM sleep and argued that it is important because REM sleep is disrupted in many pathologies that involve altered cytokine concentrations. *Id.*

Dr. Miller hypothesized two roles for fever – overheating and travel of cytokines to the brain in the mechanism of SIDS. Dr. McCusker agreed with cytokine signaling as relevant to the production of fever but disagreed that fever was the equivalent of hyperthermia in the SIDS literature. On the witness stand she drew a sharp distinction between environmental hyperthermia and overheating secondary to fever, which she called hyperpyrexia. The literature was unclear on this point. But the significant importance of fever to this case was in demonstrating the travel of peripheral cytokines stimulated by the vaccines across the blood brain barrier to the hypothalamus. Fever is the most obvious manifestation of the signaling of cytokines from the peripheral location of the vaccinations to the brain. The SIDS literature suggests that production of inflammatory cytokines IL-6, IL-10, IL-12, and IFNγ in response to DPT, Hib, and PCV7 were detected in both febrile and non-febrile groups, with febrile illness appearing 12-16 hours post vaccination.[119] NREM sleep is also implicated in SIDS. A distinctive feature of 5-HT neurons is that they exhibit differential firing rates according to the level of arousal, with increased firing during waking, decreased firing during NREM, and almost complete absence of firing during REM. Given the relationship of the firing of raphe 5-HT neurons to arousal, the medullary 5-HT system is postulated to modulate and integrate homeostatic function according to the level of arousal.[120] Thus, particularly in the deeper levels of NREM sleep, the 5-HT system is also functioning at lower levels, potentially contributing to the multi-factorial causal picture.

After review of all of the above, I have concluded that petitioners have presented a reasonable and reliable theory of vaccine causation involving the role of inflammatory cytokines acting as an extrinsic stressor in a baby with a brainstem deficit during the vulnerable time period. It is particularly important to note that the literature indicates that SIDS is likely caused by a multi-factorial process. Dr. Kinney wrote in the New England Journal of Medicine in 2009, "Current evidence suggests that SIDS involves a convergence of stressors that probably results in the asphyxia of a vulnerable infant who has defective cardiorespiratory or arousal defense systems during a critical developmental period when immature defense mechanisms are not fully integrated. Thus our current understanding of the pathogenesis of SIDS reflects the simultaneous juxtaposition of multiple events that, when taken individually, are far less powerful than the result of their chance combination."[121] In another 2009 article she wrote; "We now conceptualize SIDS as the biologic version of the perfect storm, in which the simultaneous and chance combination of multiple events is far more powerful than any individual event alone."[122]

[121] Kinney & Thach (2009), Exhibit A-4 at 7.

[122] Kinney et al. (2009), Exhibit 13-H at 539.

I have concluded that the petitioners have demonstrated by a preponderance of the evidence that the vaccines can and likely did play a critical role in this child's death by stimulating the production of inflammatory cytokines that suppressed the respiratory response system and caused the vulnerable infant to be unable to respond in the normal way to the accumulation of carbon dioxide in his system. Accordingly, petitioners have satisfied the requirement of *Althen* Prong One by presenting a reasonable explanation of how the vaccine could cause or substantially contribute to the child's death.

C. *Althen* Prong Two

Althen Prong Two requires the demonstration of a logical cause and effect as to how the vaccine caused the harm, in this case the sudden unexplained death of J.B. Under *Althen* Prong Two, petitioners must prove that there is a "logical sequence of cause and effect showing that the vaccination was the reason for the injury." *Capizzano,* 440 F.3d at 1324 (quoting *Althen,* 418 F.3d at 1278).

Dr. Miller testified that it was his diagnosis that J.B. died of SIDS and that the vaccines were a substantial contributing factor to his death. Tr. 126. Having accepted the theory of a causal role of vaccine stimulated cytokines as an exogenous factor converging with the first two prongs of the Triple Risk Model, the question of logical cause and effect requires a review of the likely mechanism and comparing it to the operative facts of the case. Kashiwagi in particular found that cytokines began to be produced 6 hours after stimulation and increased until 24 hours, showing the same level thereafter. Higher levels of IL-1B, IL-6, G-CSF, and TNFα were produced in that study by the concurrent stimulation of three vaccines than by one alone.[123] J.B. received seven vaccines at his 4 to 5 month well baby visit with his pediatrician on September 2, 2011. He was carefully examined and documented to be in entirely good health the day before. Overnight, he developed a mild fever, consistent with cytokine signaling from the vaccination site to the brain. In the early afternoon of September 3, he died during his nap.

Dr. Miller discussed the logical sequence of cause and effect explaining how he believed the vaccines acted as an exogenous stressor which caused J.B. to succumb to SIDS. He noted that J.B. was a "healthy infant… developing normally." Exhibit 13 at 4. He was "immunologically normal." Tr. 61. Therefore, after receiving vaccinations, his body mounted an innate immune response including the production of cytokines. Exhibit 13 at 6; Exhibit 16 at 1; Tr. 62. Those cytokines circulated in J.B.'s body, going to the central nervous system. Exhibit 13 at 6; Tr. 62. These peripheral cytokines interacted with the hypothalamus to provoke fever the night after the vaccinations and during the following day (before J.B.'s death). Exhibit 13 at 6; Exhibit 16 at 1; Tr. 62-64. "Those cytokines then acted in the brainstem which was already deficient in serotoninergic drive for respiratory effort, leading to an apneic episode from which he did not recover, i.e., SIDS." Exhibit 13 at 6; *see also* Tr. 62 (the cytokines "depress[ed the] 5-HT system in a defective medulla, leading to SIDS during sleep").

[123] Exhibit 17 at 679.

He opined that there was "no other demonstrable inciting event" for J.B.'s death. Exhibit 13 at 1. There was no evidence of the fever being related to anything other than J.B.'s vaccinations. Tr. 66. The autopsy did not identify any other infectious processes. Tr. 66.[124]

On cross-examination, Dr. Miller stated that J.B. was placed on his back but was found on his side, which demonstrates that he was able to "move around." Tr. 92. However, J.B. did not pass away until "something else intervened." Tr. 85. Based on his theory and the temporal association, Dr. Miller opined that the vaccines were the intervening factor that caused J.B.'s death. Tr. 85.

An innate immune response to either mild infection or to a vaccine is likely to be fast and begins the process of immune attack of a foreign antigen. Part of that response is the triggering of cytokines to signal further response in the immune system. The triggering of the innate immune system by vaccination is necessary and fundamental to producing the adaptive response and immune memory which vaccines are designed to produce. After review and consideration of all of the testimony and the literature submitted, I have concluded that Dr. Miller has presented a reasonable and persuasive theory that the cytokine cascade triggered by the innate response to the vaccine antigens is similar to the cytokine response to a mild infection, and that the inflammatory cytokines had an immune modulatory effect on J.B.'s impaired medullary 5-HT system causing a prolonged apneic event resulting in his death. As such, the progression from vaccination to an unexplained death within approximately 28 hours is logical.

This logical progression is also consistent with reports of at least mildly elevated SIDS deaths in some studies such as Traversa, which found a 2.0 relationship in the first 7 days.[125] Goldman reported a statistically significant increase in deaths when 5 to 8 vaccines were administered simultaneously as opposed to 1 to 4.[126] Ottaviani[127] and Zinka[128] reported on SIDS deaths within 48 hours of receiving vaccinations. Other studies, such as Kuhnert[129], found neither a protective effect nor elevated risk, but Kuhnert noted that the small number of cases is a problem with the three case control studies he reviewed, particularly in view of the short time periods under investigation. According to Kuhnert, this problem was illustrated by the very broad confidence intervals of estimates that were related to the first few days. *Id.* at 2355.

---

[124] Dr. Miller noted that there were bacterial growth and food particles in J.B.'s lungs and epithelial cells in the upper airways. He opined that this was not evidence of a separate infectious process. He agreed with the medical examiner that these were terminal or resuscitative sequelae. Tr. 17-18; 66; 352-53.

[128] Zinka et al. (2006), Exhibit 13-S.

[129] Kuhnert et al. (2012), Exhibit C-20.

The statistical prevalence of boys, African Americans and premature babies among the victims of SIDS also seems to be clear and causes their inclusion as intrinsic risk factors. I think it is reasonable to question in this case whether the influence of prematurity would still be a likely factor, given that he had nearly reached the age of five months and appeared to be developing very well. It is also reasonable to question whether the statistical prevalence of African Americans should be a significant factor, as it is often speculated that this may be a function of socioeconomic status and poor medical care. This child appeared to have been living in a two-parent household, with attentive parents, was well-nourished, and was receiving good medical care. The role of his male gender may well have been important, as Dr. Kinney has reported a greater reduction in 5-HT-1A in the medullary raphe in males compared to females dying of SIDS.[130]

Given that Dr. Miller's thesis and that of much of the literature for the Triple Risk Model is that SIDS results from the convergence of multiple factors, it seems likely that his male gender may well have been a contributing intrinsic factor that may have amplified the effect of the cytokine response to the vaccines on the day that he died. But, his gender, his race, and his prematurity – all intrinsic factors – do not explain his death without the interaction with a critical extrinsic factor, which I have concluded was likely the cytokines triggered by the vaccines which depressed his 5-HT system sufficiently that he did not respond when carbon dioxide became elevated in his system.

The evidence for J.B.'s death occurring as a result of his having turned to his side without a causal input from another significant extrinsic factor such as the vaccine stimulated cytokines suppressing his response system is weak in this case. As noted above, the Academy of Pediatrics recommends leaving a child in the assumed position when he has rolled from his back presumably because it is also likely that he can push up and lift his head by the time he can roll. This capability was documented in J.B's case by his pediatrician. Although there was a flat pillow and a light blanket in the bed, J.B.'s mother told the police investigators that his head was not covered and that his head was turned downward only slightly. The scene investigation noted her report that J.B.'s mouth and nose were not covered. Exhibit 7 at 5. It was described that he had been put to sleep in the middle of the bed. Thus, there is no evidence in this case that the baby's breathing passages were obstructed or that he was breathing into an air pocket. The possibility of rebreathing carbon dioxide in that position cannot be ruled out, but seems less likely based upon this evidence derived from the extensive interviews and the site re-enactment performed by the responding police. Thus, even if the side- sleeping position did cause some rebreathing of carbon dioxide, I have concluded from the evidence that it is most likely that the cytokines stimulated by the vaccines caused suppression of the already impaired medullary serotonin system with the consequent failure to chemically sense elevated carbon dioxide, which caused the ultimate failure to arouse and to breathe normally thus substantially contributing to the death of J.B

The emphasis of the Triple Risk Model on prone sleeping has had a powerful impact in reducing SIDS deaths by approximately 50%. But there remains a significant number of SIDS deaths each year, some of which are likely related to continued prone-sleeping and some to side-sleeping. But the co-occurrence of mild infection in the statistics in nearly 50% of cases raises a

[130] Kinney et al. (2009), Exhibit 13-H at 532.

significant issue about the operative extrinsic risk factor or factors in the remaining cases, including many that are found supine. In this case, an apparently perfectly healthy child was found dead a day after vaccination, having had a mild fever in the interim without evidence of infection. He was not prone sleeping but had turned to his side, with no evidence that his breathing passages were in any way impaired. Significant literature introduced demonstrates that the triggering of inflammatory cytokines in response to vaccines is similar to that raised in response to mild infection. J.B.'s post-vaccinal fever provided confirmation of responsive cytokine activity. The cause and effect between the vaccines, the cytokines triggered by the vaccines, and their co-occurrence with other intrinsic and/or extrinsic risk factors in the presence of a defective or underdeveloped brainstem seems likely to have produced the perfect storm that resulted in J.B.'s death. Thus, I am persuaded that petitioners have proved prong two.

D. *Althen* Prong Three

Under *Althen* prong three, petitioners must provide "preponderant proof that the onset of symptoms occurred within a timeframe for which, given the understanding of the disorder's etiology, it is medically acceptable to infer causation-in-fact." *De Bazan*, 539 F.3d at 1352. The acceptable temporal association will vary according to the particular medical theory advanced in the case. *See Pafford*, 451 F.3d at 1358. A temporal relationship between a vaccine and an injury, standing alone, does not constitute preponderant evidence of vaccine causation. *See, e.g.*, *Veryzer v. Sec'y of Health & Human Servs.*, 100 Fed. Cl. 344, 356 (2011) (explaining that "a temporal relationship alone will not demonstrate the requisite causal link and that petitioner must posit a medical theory causally connecting the vaccine and injury").

Dr. Miller stated that the available evidence is that foreign antigens, like those contained in vaccinations, activate the production of cytokines "within hours" and that production "peaks within 2 to at most 4 days." Exhibit 16 at 1. Thus, a vulnerable infant who receives vaccinations is most likely to suffer a fatal event if one is to occur "within the first 48 hours to at most 4 days." Exhibit 13 at 5. Dr. Miller opined that J.B.'s death was "well within this vulnerable period." *Id.*

In this case, the timing of the innate immune response to the multiple scheduled vaccinations that J.B. received on September 2, to his death the following afternoon appears entirely appropriate for an innate immune response in the vulnerable risk period for SIDS. It is also consistent with reports of at least mildly elevated SIDS deaths in some studies and reports of deaths that occur within the first several days after the vaccination. In this case, one day post-vaccination is appropriate timing, in that inflammatory cytokines stimulated during the innate immune response to the vaccine antigens are likely to be active in close proximity to the stimulating event. As Dr. Miller stated, an adverse event that can be caused by the inflammatory cytokine response to vaccine antigens would be likely to occur within a few days of the vaccination. The cytokine response has been shown by Kashiwagi[131] to occur within 6 to 24 hours of the vaccination, and the very essence of the innate immune response is one that occurs rapidly after the invasion by a foreign antigen. As noted above, that rapid innate immune response is necessary to initiate the ultimate adaptive immune response necessary to achieve the

[131] Kashiwagi et al. (2014), Exhibit 17 at 679.

design purpose of vaccination. The close temporal relationship of the child's death to the receipt of seven vaccines is reasonable and consistent with the theory of neuro-modulation in the arcuate nucleus by the cytokine response to the vaccines. Accordingly, I am persuaded that prong three of *Althen* has been satisfied.

IV. CONCLUSION

In this case, I have concluded that petitioners have presented sufficient evidence and testimony to entitle them to compensation in the Vaccine Program. I have not concluded that vaccines present a substantial risk of SIDS. In fact, the evidence is to the contrary. The vast majority of vaccine recipients do not succumb to SIDS. Under the multi-factorial analysis of the Triple Risk Model, it is theorized that the ultimate fatal event may occur when multiple factors converge during this vulnerable period to cause death when one stressor acting alone may not have. As Dr. Kinney wrote, "Current evidence suggests that SIDS involves a convergence of stressors that probably results in the asphyxia of a vulnerable infant who has defective cardiorespiratory or arousal defense systems during a critical developmental period when immature defense mechanisms are not fully integrated. The convergence of these factors appears to be far more powerful than any one taken individually."[132] Thus, even if J.B. were rebreathing some carbon dioxide on this occasion, it was likely the combination with the cytokines that caused depression of the 5-HT system that caused his death by blunting the normal chemosensitive response to excess carbon dioxide. The multi-factorial analysis, including vaccines as an extrinsic risk factor, meets the *Shyface* standard that the vaccine need not be the sole or even predominant factor but must be a "but for cause" and a substantial factor in causing the death. *Shyface*, 165 F.3d at 1352. In this case, I have concluded, after review of the evidence, that it is more likely than not that the vaccines played a substantial causal role in the death of J.B. without the effect of which he would not have died. The role of inflammatory cytokines as neuro-modulators in the infant medulla has been well described and is likely the reason for a significant number of SIDS deaths occurring in conjunction with mild infection. I have concluded that it is more likely than not that the vaccine-stimulated cytokines had the same effect in this vulnerable infant during sleep.

Accordingly, petitioners are entitled to compensation. A separate damages order will issue.

IT IS SO ORDERED.

SPIDER Bites CDC

By Carey Gillam

Concerns about the inner workings of the U.S. Centers for Disease Control and Prevention (CDC) have been mounting in recent months amid disclosures of cozy corporate alliances. Now a group of more than a dozen senior scientists have reportedly lodged an ethics complaint alleging the federal agency is being influenced by corporate and political interests in ways that short-change taxpayers.

A group calling itself CDC Scientists Preserving Integrity, Diligence and Ethics in Research, or CDC SPIDER, put a list of complaints in writing in a letter to the CDC Chief of Staff and provided a copy of the letter to the public watchdog organization U.S. Right to Know (USRTK). The members of the group have elected to file the complaint anonymously for fear of retribution.

"It appears that our mission is being influenced and shaped by outside parties and rogue interests... and Congressional intent for our agency is being circumvented by some of our leaders. What concerns us most, is that it is becoming the norm and not the rare exception," the letter states. "These questionable and unethical practices threaten to undermine our credibility and reputation as a trusted leader in public health."

The complaint cites among other things a "cover up" of the poor performance of a women's health program called the Well-Integrated Screening and Evaluation for Woman Across the Nation, or WISEWOMAN. The program provides standard preventive services to help 40- to 64-year-old women reduce their risks for heart disease, and promote healthy lifestyles. CDC currently funds 21 WISEWOMAN programs through states and tribal organizations. The complaint alleges there was a coordinated effort within the CDC to misrepresent data given to Congress so that it appeared the program was involving more women than it actually was.

"Definitions were changed and data 'cooked' to make the results look better than they were," the complaint states. "An 'internal review' that involved staff across CDC occurred and its findings were essentially suppressed so media and/or Congressional staff would not become aware of the problems."
The letter mentions that Congresswoman Rosa DeLauro, a Democrat from Connecticut, who has been a proponent of the program, has made inquiries to CDC regarding the data. A spokesman for her office, confirmed as much.

The complaint also alleges that staff resources that are supposed to be dedicated to domestic programs for Americans are instead being directed to work on global health and research issues.

And the complaint cites as "troubling" the ties between soft drink giant Coca-Cola Co., an advocacy group backed by Coca-Cola, and two high-ranking CDC officials - Dr. Barbara Bowman who directed the CDC's Division for Heart Disease and Stroke Prevention until retiring in June, and Dr. Michael Pratt, senior Advisor for Global Health in the National Center for Chronic Disease Prevention and Health Promotion (NCCDPHP) at the CDC.

Bowman, retired after revelations of what the complaint called an "irregular" relationship with Coca-Cola and the nonprofit corporate interest group set up by Coca-Cola called the International Life Sciences Institute (ILSI). Email communications obtained through Freedom of Information Act (FOIA) requests by USRTK revealed that in her CDC role, Bowman had been communicating regularly with - and offering guidance to - a leading Coca-Cola advocate seeking to influence world health authorities on sugar and beverage policy matters.

Emails also suggested that Pratt has a history of promoting and helping lead research funded by Coca-Cola while being employed by the CDC. Pratt also has been working closely with ILSI, which advocates for the agenda of beverage and food industries, emails obtained through FOIA showed. Several research papers co-written by Pratt were at least partly funded by Coca-Cola, and Pratt has received industry funding to attend industry-sponsored events and conferences.

Last month, Pratt took a position as Director of the University of California San Diego Institute for Public Health. Next month, ILSI is partnering with the UCSD to hold a forum related to "energy balance behavior," planned for November 30 to December 1 of this year. One of the moderators is another CDC scientist, Janet Fulton, Chief of the CDC's Physical Activity and Health Branch. Pratt is on annual leave from the CDC during his stint in San Diego, according to the CDC.

The forum fits into the messaging of "energy balance" that Coca-Cola has been pushing. Consumption of sugar-laden foods and beverages is not to blame for obesity or other health problems; a lack of exercise is the primary culprit, the theory goes.

Experts in the nutrition arena have said that the relationships are troubling because the mission of the CDC is protecting public health, and yet certain CDC officials appear to be close with an industry that, studies say, is linked to about 180,000 deaths per year worldwide, including 25,000 in the United States. The CDC is supposed to be addressing rising obesity rates among children, not advancing beverage industry interests.

CDC spokeswoman Kathy Harben would not address what the agency might be doing, if anything, in response to the SPIDER complaint, but she said the agency makes use of a "full range of federal ethics statutes, regulations, and policies" that apply to all federal employees."

"CDC takes seriously its responsibility to comply with the ethics rules, inform employees about them, and take steps to make it right any time we learn that employees aren't in compliance," Harben said. "We provide regular training to and communicate with staff on how to comply with ethics requirements and avoid violations."

The SPIDER group complaint ends with a plea for CDC management to address the allegations; to "do the right thing."

Let's hope someone is listening.

THE HILL

The CDC is being influenced by corporate and political interests

BY CAREY GILLAM, CONTRIBUTOR - 10/17/16 06:00 PM EDT

Concerns about the inner workings of the U.S. Centers for Disease Control and Prevention (CDC) have been mounting in recent months amid disclosures of cozy corporate alliances. Now a group of more than a dozen senior scientists have reportedly lodged an ethics complaint alleging the federal agency is being influenced by corporate and political interests in ways that shortchange taxpayers.

A group calling itself CDC Scientists Preserving Integrity, Diligence and Ethics in Research, or (CDC SPIDER), put a list of complaints in writing in a letter to CDC Chief of Staff and provided a copy of the letter to the public watchdog organization U.S. Right to Know (USRTK). The members of the group have elected to file the complaint anonymously for fear of retribution.

"It appears that our mission is being influenced and shaped by outside parties and rogue interests... and Congressional intent for our agency is being circumvented by some of our leaders. What concerns us most, is that it is becoming the norm and not the rare exception," the letter states. "These questionable and unethical practices threaten to undermine our credibility and reputation as a trusted leader in public health."

The complaint cites among other things a "cover up" of the poor performance of a women's health program called the Well-Integrated Screening and Evaluation for Woman Across the Nation, or WISEWOMAN. The program provides standard preventive services to help 40- to 64-year-old women reduce their risks for heart disease, and promote healthy lifestyles. CDC currently funds 21 WISEWOMAN programs through states and tribal organizations. The complaint says there was a coordinated effort within the CDC to misrepresent data given to Congress so that it appeared the program was involving more women than it actually was.

"Definitions were changed and data 'cooked' to make the results look better than they were," the complaint states. "An 'internal review' that involved staff across CDC occurred and its findings were essentially suppressed so media and/or Congressional staff would not become aware of the problems."

The letter mentions that Congresswoman Rosa DeLauro, a Democrat from Connecticut, who has been a proponent of the program, has made inquiries to CDC regarding the data. A spokesman for her office, confirmed as much.

The complaint also alleges that staff resources that are supposed to be dedicated to domestic programs for Americans are instead being directed to work on global health and research issues.

And the complaint cites as "troubling" the ties between soft drink giant Coca-Cola Co., an advocacy group backed by Coca-Cola, and two high-ranking CDC officials - Dr. Barbara Bowman who directed the CDC's

Division for Heart Disease and Stroke Prevention until retiring in June, and Dr. Michael Pratt, senior Advisor for Global Health in the National Center for Chronic Disease Prevention and Health Promotion (NCCDPHP) at the CDC.

Bowman, retired after revelations of what the complaint called an "irregular" relationship with Coca-Cola and the nonprofit corporate interest group set up by Coca-Cola called the International Life Sciences Institute (ILSI). Email communications obtained through Freedom of Information Act (FOIA) requests by USRTK revealed that in her CDC role, Bowman had been communicating regularly with - and offering guidance to - a leading Coca-Cola advocate seeking to influence world health authorities on sugar and beverage policy matters.

Emails also suggested that Pratt has a history of promoting and helping lead research funded by Coca-Cola while being employed by the CDC. Pratt also has been working closely with ILSI, which advocates for the agenda of beverage and food industries, emails obtained through FOIA showed. Several research papers co-written by Pratt were at least partly funded by Coca-Cola, and Pratt has received industry funding to attend industry-sponsored events and conferences. Last month, Pratt took a position as Director of the University of California San Diego Institute for Public Health. Next month, ILSI is partnering with the UCSD to hold a forum related to "energy balance behavior," planned for November 30 to December 1 of this year. One of the moderators is another CDC scientist, Janet Fulton, Chief of the CDC's Physical Activity and Health Branch. Pratt is on annual leave from the CDC during his stint in San Diego, according to the CDC.

The forum fits into the messaging of "energy balance" that Coca-Cola has been pushing. Consumption of sugar-laden foods and beverages is not to blame for obesity or other health problems; a lack of exercise is the primary culprit, the theory goes.

Experts in the nutrition arena have said that the relationships are troubling because the mission of the CDC is protecting public health, and yet certain CDC officials appear to be close with an industry that, studies say, is linked to about 180,000 deaths per year worldwide, including 25,000 in the United States. How many scientists fabricate and falsify research? A systematic review and meta-analysis of survey data.

Fanelli D[1].

Author information

Abstract

The frequency with which scientists fabricate and falsify data, or commit other forms of scientific misconduct is a matter of controversy. Many surveys have asked scientists directly whether they have committed or know of a colleague who committed research misconduct, but their results appeared difficult to compare and synthesize. This is the first meta-analysis of these surveys. To standardize outcomes, the number of respondents who recalled at least one incident of misconduct was calculated for each question, and the analysis was limited to behaviours that distort scientific knowledge: fabrication, falsification, "cooking" of data, etc... Survey questions on plagiarism and other forms of professional misconduct were excluded. The final sample consisted of 21 surveys that were included in the systematic review, and 18 in the meta-analysis. A pooled weighted average of 1.97% (N = 7, 95%CI: 0.86-4.45) of scientists admitted to have fabricated, falsified or modified data or results at least once--a serious form of misconduct by any standard--and up to 33.7% admitted other questionable research practices. In surveys asking about the behaviour of colleagues, admission rates were 14.12% (N = 12, 95% CI: 9.91-19.72) for falsification, and up to 72% for other questionable research practices. Meta-regression showed that self reports surveys, surveys using the words "falsification" or "fabrication", and mailed surveys yielded lower percentages of misconduct. When these factors were controlled for, misconduct was reported more frequently by medical/pharmacological researchers than others. Considering that these surveys ask sensitive questions and have other limitations, it appears likely that this is a conservative estimate of the true prevalence of scientific misconduct.

Key findings

- The Cochrane human papillomavirus (HPV) vaccine review missed nearly half of the eligible trials.
- The review was influenced by reporting bias and biased trial designs.
- Authors of Cochrane reviews should make every effort to identify all trials and the trials' limitations.

In May 2018, the Cochrane Collaboration published its review of the human papillomavirus (HPV) vaccines.[1] The review primarily assessed the vaccines' effect on precursors to cervical cancer. Cochrane has high standards for its reviews[2]; however, there were important limitations in its HPV vaccine review, which we address in this paper.

The Cochrane review missed nearly half of the eligible trials

The Cochrane review conducted trial searches up until June 2017 and included 26 randomised trials with 73 428 women.[1] In January 2018, we published an index of the study programmes of the HPV vaccines that included 206 comparative studies.[3] As of June 2017, about one-third of the 206 studies were not published and half of the completed studies listed on ClinicalTrials.gov had no results posted.[3] Although we sent our index to the Cochrane group handling the Cochrane review, the review stated that, 'nearly all end-of-study reports have been published in the peer-reviewed literature'. When we applied the Cochrane review's inclusion criteria to the 206 studies, we identified 46 completed and eligible trials. The number of randomised participants could be assessed for 42 of the 46 trials and was 121 704. With nearly half of the trials and half of the participants missing, the Cochrane authors' conclusion, 'that the risk of reporting bias may be small', was inappropriate. Fifteen of the 20 additional trials were listed on ClinicalTrials.gov; the Cochrane authors would therefore have identified more trials if they had searched ClinicalTrials.gov in more depth and searched additional trial registers (we searched 45 trial registers[3]).

The Cochrane authors stated that they 'did not include the nine-valent vaccine [Gardasil 9] ... since the randomised trials ... did not incorporate an arm with a non-HPV vaccine control'. This is not correct. The only saline placebo trial of approved HPV vaccines is a Gardasil 9 trial (V503-006; NCT01047345) that was published in 2015.[4] Its participants had previously been vaccinated with four-valent Gardasil, but according to the Cochrane review protocol,[5] this was not an exclusion criterion. Since many countries are shifting to Gardasil 9,[6] it is unfortunate that the Gardasil 9 trial was not included in the Cochrane review.

No included trial in the Cochrane review used a placebo comparator

All 26 trials included in the Cochrane review used active comparators: adjuvants (aluminium hydroxide ($Al[OH]_3$) or amorphous aluminium hydroxyphosphate sulfate [AAHS]) or hepatitis vaccines.

Adjuvants are not regulated separately from their vaccine antigens. According to the Food and Drug Administration (FDA), adjuvants are unreliable comparators.[7] One HPV vaccine manufacturer (GlaxoSmithKline that produces Cervarix) states that its aluminium-based comparator induces harms: 'higher incidences of myalgia might namely be attributable to the higher content of aluminium in the HPV vaccine (450 µg $Al[OH]_3$) than the content of aluminium in the HAV [hepatitis A] vaccine (225 µg $Al[OH]_3$)'.[8] The comparator hepatitis vaccines also used the HPV vaccines' aluminium-based adjuvant.

The Cochrane authors mistakenly used the term placebo to describe the active comparators. They acknowledged that 'The comparison of the risks of adverse events was compromised by the use of different products (adjuvants and hepatitis vaccines) administered to participants in the control group'. Nevertheless, this statement can easily be overlooked, as it comes after 7500 words about other issues in the discussion and under the heading 'Potential biases in the review process'. Active comparators was not a bias in the review process but a bias in the design of the HPV vaccine trials.

The use of active comparators probably increased the occurrence of harms in the comparator groups and thereby masked harms caused by the HPV vaccines. It is noteworthy that many women were excluded from the trials if they had received the adjuvants before or had a history of immunological or nervous system disorders; for example, in the PATRICIA trial with 18 644 women[9] and the FUTURE II trial with 12 167 women.[10] These exclusion criteria lowered the external validity of the trials and suggest that the vaccine manufacturers were worried about harms caused by the adjuvants. The criteria are not listed as warnings on the package inserts of the HPV

vaccines,[11–13] which may have led to more vaccine-related harms in clinical practice than in the trials.

The included HPV vaccine trials used composite surrogate outcomes for cervical cancer

In line with World Health Organization (WHO) recommendations,[14] the Cochrane review was based on composite surrogate outcomes: 'cervical intraepithelial neoplasia grade 2 and above [CIN2+], CIN grade 3 and above [CIN3+] and adenocarcinoma in situ [AIS]'.[1] The use of such outcomes seemed reasonable for a preliminary assessment of HPV vaccine benefits, but the outcomes can be difficult to interpret. If there were clinically important differences in the severity of the cervical lesions in the two compared groups, they may not have been apparent in the composite outcomes of CIN2+ and CIN3+. The Cochrane authors did not describe any cervical cancers in the 26 trials, although cancers did occur in the trials; for example, in the ClinicalTrials.gov entry for the VIVIANE trial, one case of 'Adenocarcinoma of the cervix' and one case of 'Cervix cancer metastatic' are listed in the HPV vaccine group (see 'Results: Serious Adverse Events').[15] Furthermore, the relationship between CIN2 and cervical cancer is not clear-cut. Most CIN2 lesions in women below age 30 regress spontaneously; an active surveillance approach has therefore been recommended for this group.[16] The Cochrane review's 26 trials mainly included women below age 30 and used frequent cervical screening (often every six months) that did not reflect real-life practice (often every three to five years[6]).

The Cochrane review incompletely assessed serious and systemic adverse events

The Cochrane authors reported that they made a 'Particular effort' to assess serious adverse events and performed a sensitivity analysis that gave them 'confidence that published and registry or website-sourced data are similar for the same study'.[1] This seems unlikely. As an example, the PATRICIA trial publication only included two thirds (1400/2028) of the serious adverse events listed on ClinicalTrials.gov. The Cochrane authors included 701 vs 699 serious adverse events (1400) from the PATRICIA trial publication (see the Cochrane reviews' 'Figure 10, Analysis 7.6.2') and 835 vs 829 serious adverse events from its ClinicalTrials.gov entry (see 'Comparison 7, Analysis 6: 7.6.2'; both analyses were called '7.6.2'). We found 1046 vs 982 serious adverse events (2028) when we summarised the data from ClinicalTrials.gov (see 'Results: Serious Adverse Events').[17]

The Cochrane authors concluded with 'high certainty' that the risk of serious adverse events was similar in the HPV vaccine groups and the comparator groups. However, the authors failed to mention that several of the included trials did not report serious adverse events for the whole trial period. For example, FUTURE I,[18] FUTURE II[10] and FUTURE III,[19] which in total included 21 441 women with up to four years follow-up, only reported serious adverse events occurring within 14 days postvaccination. Furthermore, the Cochrane authors did not explain what the serious adverse events consisted of or whether some of them were more common in the HPV vaccine groups.

The Cochrane authors found more deaths in the HPV vaccine groups than in the comparator groups. The death rate was significantly increased in women above age 25 (risk ratio [RR] 2.36, 95% confidence interval [CI] 1.10 to 5.03; no absolute numbers were provided for this subgroup analysis, but the total numbers of deaths were 51 in the HPV vaccine groups and 39 in the comparator groups). The Cochrane authors suggested that this was a chance occurrence since there was no pattern in the causes of death or in the time between vaccine administration and date of death. However, as the Cochrane review only included randomised trials, the authors cannot rule out that the increase could be caused by the HPV vaccines. A death may be coded in a way that does not raise suspicion that the vaccine caused it; for example, a 'traumatic head injury' or 'drowning' could have been caused by a 'syncope', which is a recognised harm.[11–13] As of May 2018, WHO's pharmacovigilance database—VigiBase, managed by the Uppsala Monitoring Centre (UMC)—contained 499 deaths reported as related to HPV vaccination.[20]

The Cochrane authors concluded that, 'Systemic events with general mild symptoms were similarly frequent in vaccinated recipients and placebo or control vaccine recipients'. Their Analysis 7.5 showed a non-significant increase in systemic events: RR 1.02 (95% CI 0.98 to 1.07) with a total of 9137 vs 9054 events. The Cochrane authors did not include all of their trials that were eligible for systemic events in Analysis 7.5; for example, the PATRICIA trial was not included. On ClinicalTrials.gov, PATRICIA has 7129 vs 6557 systemic events listed under 'Results: Other Adverse Events (General disorders)', which in itself is a significantly increased risk: RR 1.09 (95% CI 1.07 to 1.11).[17]

The Cochrane authors 'planned requesting data from data owners, to fill in gaps with available unpublished data', but 'due to constraints in time and other resources' they were unable to do so.[1] Considering that seven years passed from the publication of the Cochrane protocol in 2011[5] to the Cochrane review in 2018,[1] lack of time seems a poor excuse for not trying to obtain unpublished trial documents and data. More importantly, harms cannot be assessed reliably in published trial documents—especially in journal publications of industry-funded trials where even serious harms often are missing.[21] One reason may be the space restrictions that most medical journals have. As an example, the journal publication for the PATRICIA trial is 14 pages long[9] while its publicly available corresponding clinical study report is over 7000 pages long,[22] although it is an interim report that has been shortened. Clinical study reports are usually confidential documents, but they can be requested from the European Medicines Agency (EMA) and ClinicalStudyDataRequest.com (CSDR).

Despite the mentioned examples of reporting bias, the Cochrane authors judged all trials at low risk of reporting bias (see the Cochrane review's 'Figure 4: 'Risk of bias' summary').

The Cochrane review did not assess HPV vaccine-related safety signals

The Cochrane authors referred to many observational studies in their discussion that found no safety signals of harms associated with the HPV vaccines.[1] They cited WHO's Global Advisory Committee on Vaccine Safety (GACVS) that expressed 'concerns about unjustified claims of harms'. The Cochrane authors did not mention a study from 2017 by the WHO UMC that found serious harms following HPV vaccination overlapping with two syndromes: postural orthostatic tachycardia syndrome (POTS) and complex regional pain syndrome (CRPS).[23] The WHO UMC provided part of the rationale for EMA's investigation of POTS and CRPS in 2016.[24] As of May 2018, the WHO UMC VigiBase contained 526 cases of POTS and 168 cases of CRPS reported related to HPV vaccination.[20]

The Cochrane authors did not investigate whether the included trial data reported cases of POTS, CRPS or other safety signals. Instead, the authors cited EMA, which concluded that 'No causal relation could be established' between POTS or CRPS and the

HPV vaccines.[1] EMA's conclusion was based on the HPV vaccine manufacturers' own unverified assessments[24] that only included half of the eligible trials.[3] Furthermore, the HPV vaccine manufacturers search strategies for POTS and CRPS were inadequate and led to cases being overlooked.[25] As an example, in 2014, the Danish Medicines Agency (DMA) asked the HPV vaccine co-manufacturer Sanofi-Pasteur-MSD to search for specific POTS-related symptoms in its database (including dizziness, palpitations, rapid heart rate, tremor, fatigue and fainting). The manufacturer only searched for 'postural dizziness', 'orthostatic intolerance' and 'palpitations and dizziness'. The Danish Medicines Agency discovered this because only three of 26 Danish reports of POTS showed up in Sanofi's searches.[25] As another example, EMA identified six possible cases of POTS and CRPS related to Gardasil 9 that Merck had not identified.[26]

Industry trial funding and other conflicts of interest

The Cochrane authors assessed the impact of industry funding 'by meta-regression. No significant effects were observed'.[1] They stated that, 'All but one of the trials was funded by the vaccine manufacturers', which is not correct. According to ClinicalTrials.gov, this particular trial ('CVT' or 'Costa Rica trial'[1]) was sponsored by GlaxoSmithKline.[27] Therefore, all included trials were funded by the HPV vaccine manufacturers and the meta-regression was meaningless.

The Cochrane Collaboration aims to be free from conflicts of interest related to the manufacturers of the reviewed products.[28] Most of the 14 Cochrane authors on the first published protocol for the Cochrane review had major conflicts of interest related to the HPV vaccine manufacturers.[29] The Cochrane review only has four authors; three of whom had such conflicts of interest a decade ago. The review's first author currently leads EMA's 'post-marketing surveillance of HPV vaccination effects in non-Nordic member states of the European Union', which is funded by Sanofi-Pasteur-MSD that was the co-manufacturer of Gardasil.

Cochrane's public relations of the review were uncritical

The announcement of the Cochrane review on Cochrane.org under 'News' included a 'Science Media Centre roundup of third-party expert reaction to this review'.[30] Six experts were cited—all from the UK, although the Cochrane Collaboration is an international organisation. Two of the experts had financial conflicts of interest with the HPV vaccine manufactures. A third expert was responsible for vaccinations in Public Health England (PHE) that promotes the HPV vaccines. The experts highlighted the 'intensive and rigorous Cochrane analysis', 'that the HPV vaccine is the most effective way for young girls to protect themselves against cervical cancer' and that 'the vaccine causes no serious side-effects'. No expert criticised the review. In our view, this is not balanced and people with conflicts of interest in relation to the manufacturers should not be quoted in relation to a Cochrane review. Richard Smith—the former editor of the British Medical Journal (BMJ)—described medical journals as an extension of the marketing arm of the drug industry.[31] We are concerned that some observers may see Cochrane reviews in the same light when Cochrane publishes such public relation messages.

Conclusion

Part of the Cochrane Collaboration's motto is 'Trusted evidence'. We do not find the Cochrane HPV vaccine review to be 'Trusted evidence', as it was influenced by reporting bias and biased trial designs. We believe that the Cochrane review does not meet the standards for Cochrane reviews or the needs of the citizens or healthcare providers that consult Cochrane reviews to make 'Informed decisions', which also is part of Cochrane's motto. We recommend that authors of Cochrane reviews make every effort to identify all trials and their limitations and conduct reviews accordingly.

Don't Believe Everything You Read About Flu Deaths

The CDC's decision to play up flu deaths dates back a decade, when it realized the public wasn't following its advice on the flu vaccine. During the 2003 flu season "the manufacturers were telling us that they weren't receiving a lot of orders for vaccine,"Dr. Glen Nowak, associate director for communications at CDC's National Immunization Program, told National Public Radio.

01/24/2014 05:40 EST | **Updated** 03/26/2014 05:59 EDT

Flu results in "about 250,000 to 500,000 yearly deaths" worldwide, Wikipedia tells us. "The typical estimate is 36,000 [deaths] a year in the United States," reports NBC, citing the Centers for Disease Control. "Somewhere between 4,000 and 8,000 Canadians a year die of influenza and its related complications, according to the Public Health Agency of Canada," the *Globe and Mail* says, adding that "Those numbers are controversial because they are estimates."

"Controversial" is an understatement, and not just in Canada, and not just because the numbers are estimates. The numbers differ wildly from the sober tallies recorded on death certificates -- by law every certificate must show a cause -- and reported by the official agencies that collect and keep vital statistics.

According to the National Vital Statistics System in the U.S., for example, annual flu deaths in 2010 amounted to just 500 per year -- fewer than deaths from ulcers (2,977), hernias (1,832) and pregnancy and childbirth (825), and a far cry from the big killers such as heart disease (597,689) and cancers (574,743). The story is similar in Canada, where unlikely killers likewise dwarf Statistics Canada's count of flu deaths.

Even that 500 figure for the U.S. could be too high, according to analyses in authoritative journals such as the American Journal of Public Health and the British Medical Journal. Only about 15-20 per cent of people who come down with flu-like symptoms have the influenza virus -- the other 80-85 per cent actually caught rhinovirus or other germs that are indistinguishable from the true flu without laboratory tests, which are rarely done. In 2001, a year in which death certificates listed 257 Americans as having died of flu, only 18 were positively identified as true flus. The other 239 were simply assumed to be flus and most likely had few true flus among them.

"U.S. data on influenza deaths are a mess," states a 2005 article in the British Medical Journal entitled "Are U.S. flu death figures more PR than science?" This article takes issue with the 36,000 flu-death figure commonly claimed, and with describing "influenza/pneumonia" as the seventh leading cause of death in the U.S.

"But why are flu and pneumonia bundled together?" the article asks. "Is the relationship so strong or unique to warrant characterizing them as a single cause of death?"

The article's answer is no. Most pneumonia deaths are unrelated to influenza. For example, "stomach acid suppressing drugs are associated with a higher risk of

community-acquired pneumonia, but such drugs and pneumonia are not compiled as a single statistic," explained Dr. David Rosenthal, director of Harvard University Health Services. "People don't necessarily die, per se, of the [flu] virus -- the viraemia. What they die of is a secondary pneumonia."

Pneumonia, according to the American Lung Association, has more than 30 different causes, influenza being but one of them. The CDC itself acknowledges the slim relationship, saying "only a small proportion of deaths... only 8.5 per cent of all pneumonia and influenza deaths [are] influenza-related."

Because death certificates belie claims of numerous flu deaths, CDC enlisted computer models to arrive at its 36,000 flu-death estimate. But even here it needed to bend conventional medical terminology to arrive at compelling death numbers.

"Cause-of-death statistics are based solely on the underlying cause of death [internationally defined] as 'the disease or injury which initiated the train of events leading directly to death,'" explains the National Center for Health Statistics. Because the flu was rarely an "underlying cause of death," the CDC created the sound-alike term, "influenza-associated death."

Using this new, loose definition, CDC's computer models could tally people who died of a heart ailment or other causes after having the flu. As William Thompson of the CDC's National Immunization Program admitted, influenza-associated mortality is "a statistical association ... I don't know that we would say that it's the underlying cause of death."

The CDC's decision to play up flu deaths dates back a decade, when it realized the public wasn't following its advice on the flu vaccine. During the 2003 flu season "the manufacturers were telling us that they weren't receiving a lot of orders for vaccine,"Dr. Glen Nowak, associate director for communications at CDC's National Immunization Program, told National Public Radio. "It really did look like we needed to do something to encourage people to get a flu shot."

The CDC's response was its "Seven-Step 'Recipe' for Generating Interest in, and Demand for, Flu (or any other) Vaccination," a slide show Nowak presented at the 2004 National Influenza Vaccine Summit.

Here is the "Recipe that fosters influenza vaccine interest and demand," in the truncated language that appears on his slides: "Medical experts and public health authorities [should] publicly (e.g. via media) state concern and alarm (and predict dire outcomes) - and urge influenza vaccination." This recipe, his slide show indicated, would result in "Significant media interest and attention ... in terms that motivate behavior (e.g. as 'very severe,' 'more severe than last or past years,' 'deadly')." Other emotive recommendations included fostering "the perception that many people are susceptible to a bad case of influenza" and "Visible/tangible examples of the seriousness of the illness (e.g., pictures of children, families of those affected coming forward) and people getting vaccinated (the first to motivate, the latter to reinforce)."

The CDC unabashedly decided to create a mass market for the flu vaccine by enlisting the media into panicking the public. An obedient and unquestioning media obliged by hyping the numbers, and 10 years later it is obliging still.

Editorial

Mistaken identity: seasonal influenza versus influenza-like illness

Readers of *Clinical Evidence* who are interested in influenza will have been struck by the disparity between policy recommendations and the clinical evidence of the performance of inactivated influenza vaccines.[1][2] For example, there are few RCTs assessing the effectiveness of inactivated vaccines in children and the elderly. Only five RCTs have been carried out in elderly people, of which only one was carried out in the past 2 decades using vaccines available today.[3] Although the evidence is more robust in healthy adults, and partly supports the use of vaccines, this is the population who are universally considered to need them least.[1][2]

The reasons for the contradictions between policy and evidence, and the dearth of corroborating evidence on vaccine performance, are complex and include: the relative rarity of influenza; the current confusion between influenza-like illness and influenza (a simplistic aetiopathogenic model hide-bound by Henle-Koch's postulates of one germ, one disease, one solution); the inability of vaccines to protect populations from an ever-mutating agent; and the difficulty of conducting meaningful prospective studies to assess vaccine efficacy. In addition, the powerful image of influenza depicted by the media is not proportional to the actual threat. The "monster at your door" fame of influenza helps to create preventive expectations that are unachievable with today's technology and with only partial reading of the evidence. For example, we know that in the past 2 decades influenza vaccine studies have risen in prominence in the scientific media, possibly as a result of pharmaceutical sponsorship and the need of larger journals to boost their revenue by selling bulk reprints and subscriptions to offset the decline in print-based returns.[4][5] This rise in prominence is, however, in contrast to the threat from influenza. In the US, the influenza-related mortality rate of the past 20 years has not increased, but plateaued.

Here, I examine the evidence for and the impact of the first two factors listed above — the incidence of influenza, and the masking of its rarity by the systematic failure to distinguish between influenza (a disease) and influenza-like illness (a syndrome, caused also in minor part by influenza viruses).

The causal relationship between the two is scarcely investigated and is frequently overlooked, perhaps because of technical difficulties in quantifying the incidence of "seasonal" influenza and its complications. I must confess that I realised the importance of incidence only after having carried out scores of Cochrane reviews and updates on influenza vaccines and antivirals. I started from the end (the interventions) instead of concentrating on the beginning (the epidemiology of influenza and the other respiratory viruses).

The incidence statistic for influenza, which is often taken for granted, is estimated from virological testing of symptomatic people (so-called viral circulation). What is often poorly understood is that the patient presenting to a physician typically has a syndrome (influenza-like illness, or ILI) that can be caused by various agents. Only a proportion of these syndromes is caused by influenza A and B viruses, but differential diagnosis on clinical grounds alone is not possible.[6][7] Google's near real-time instrument, Flu Trends, provides an excellent example of the confusion generated from following the inaccurate equation "influenza = ILI".[7] Users of Flu Trends think they are following the spread of influenza, while in reality the site depicts the spread of ILI.

To determine (not estimate) the incidence of influenza at any one time, virological testing of a truly random sample of people with ILI is needed. At the same time, testing for all other major causal agents should be carried out, but this is not typically done. In addition, it is not known, or cannot be estimated accurately, how many people have ILI at a given time, which further complicates calculation of incidence. The consequence of this is biased estimates of incidence, where attention is focused on testing for influenza viruses in non-randomly identified people with ILI. Ignorance of the presence of other causal agents has made us blind to the complex ecology of respiratory viruses. How can systematic reviews obviate such tunnel vision?

At present, the only method of determining influenza incidence with a high level of accuracy is to use the control arms of influenza vaccines and antiviral studies. From these, reliable denominators (i.e., number of people with ILI) and numerators (i.e., number of people with influenza and its complications) can be calculated. This is simpler than it sounds. The Cochrane Vaccines Field group has a database of all identifiable studies from 1948 to 2007 that assess the effectiveness of inactivated influenza vaccines and report clinical outcomes (as opposed to surrogate outcomes, such as antibody responses). These are the studies that populate our Cochrane reviews and their updates. The database also comprises studies excluded from the reviews, provided they are comparative and report clinical outcomes. Data available in these studies are collected during the active follow-up of formal studies (often prospectively), in which participant controls with ILI are typically tested (figure 1). As such, they are the optimum data available on influenza incidence. However, high loss to follow-up detracts from the reliability of the data. The data depicted in figure 1 come from the control arms of 95 vaccine comparative studies published between 1965 and 2005 that report, between them, several million observations on incidence.

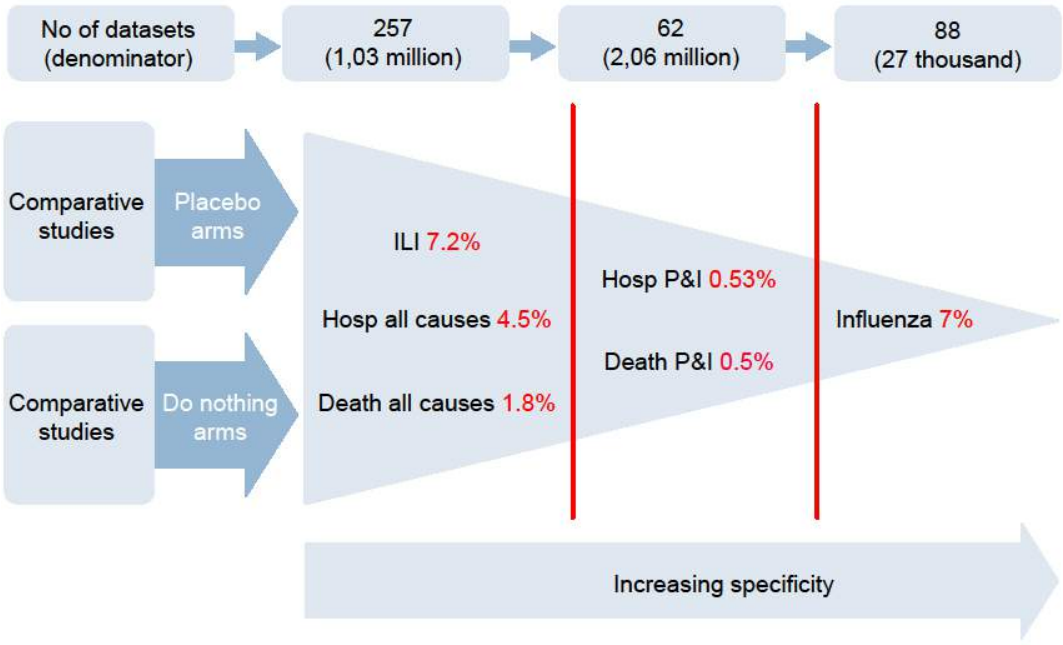

Figure 1. Graphic representation of funnel data in the general population. ILI, influenza-like illness; P&I, pneumonia and influenza (includes ICD 9 codes 480–488).

The availability of a considerable body of data, as figure 1 illustrates, does not always generate a strong evidence base on which to judge efficacy. In the case of inactivated influenza vaccines, the key issue in interpreting the data is over-reliance on non-specific outcomes, such as death from all causes, which may have little to do with influenza-related death. Studies with such non-specific outcomes have been purported to show the effectiveness of influenza vaccines, but actually they only introduce confounding. The funnel in figure 1 exemplifies the richness of data on non-specific outcomes, and the paucity of data on laboratory confirmed influenza A or B. However, this is only part of the story, as data from control arms of comparative vaccine studies seldom look for other viral agents among the samples. Control arms show what is certainly influenza (as is their objective), but do not identify other agents. One of the subliminal effects of this is that observers focus exclusively on one agent, ignoring the rest.

In addition, the data allow a best guess as to how prevalent influenza is, but not its complications. Based on studies in the Cochrane database, incidence of influenza is estimated at around 7%. However, the control arms of the 95 studies identified evaluate people with ILI. Therefore, 7% is not the absolute incidence of influenza in the general population, but is rather the portion of ILI that is caused by influenza, making the incidence of influenza itself in the general population much smaller (approximately 0.5%). Studies of influenza vaccines do not serve well for apportioning slices of the ILI "pie" to non-influenza agents, as they seek only influenza. To do this, we must turn to pie studies, which are a systematic assembling of data from the few studies that followed a defined population, and swabbed ILI symptomatic people for all major agents.

A brief review of pie studies published in the past decade and available in the Cochrane database paints a remarkably similar picture to that of control arms, with an incidence of influenza of 0.5% to 1% of ILIs. Figure 2 shows how the systematically assembled evidence from control arms fits with that from pie studies. Surprisingly, most ILIs cannot be attributed to a specific causal agent. Although many other conclusions can be drawn from observations of pie slices, our aim here is to discuss why influenza inactivated vaccine performance is poor, and why most studies rely on non-specific outcomes, such as death from all causes, and hospitalisations for pneumonia and influenza (which are not usually based on virological testing). One possible answer is that seasonal influenza is a relatively rare and benign condition, with an incidence not exceeding 1% in the general population during autumn and winter months.

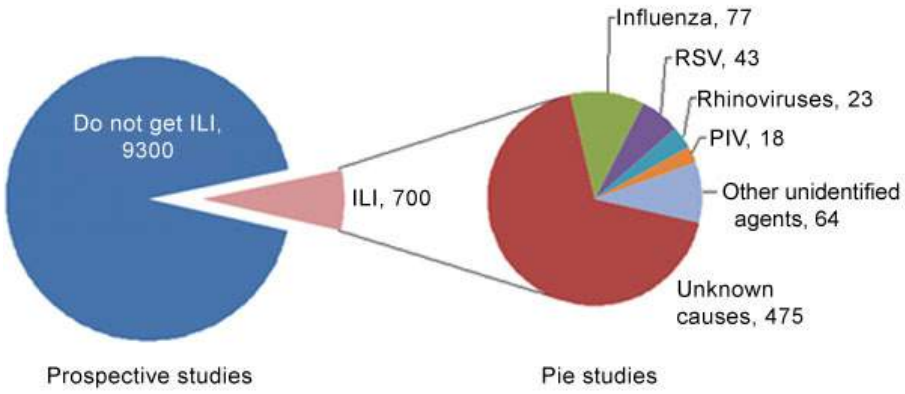

Figure 2. Incidence of influenza-like illnesses (ILI) per 10,000 people (calculated from prospective studies), with breakdown by agent, based on information in pie studies.

Vaccine effectiveness (expressed as a percentage) is calculated by subtracting the ratio of incidence in vaccinated and unvaccinated populations from 1. Therefore, if the incidence in the unvaccinated population is low, then the ratio will be close to 1 and effectiveness will be low. So, vaccines seem to be less effective in illnesses with low incidence. A systematic approach to best evidence completes the picture, and explains what is observed in trials and other comparative studies. In summary, evidence presented here points to influenza being a relatively rare cause of ILI and a relatively rare disease. It follows that vaccines may not be appropriate preventive interventions for either influenza or ILI.

Why have three long-running Cochrane Reviews on influenza vaccines been stabilised?

Three Cochrane Reviews focussing on the prevention of influenza in healthy adults, healthy children, and in the elderly are long-running reviews under the same senior author team. The protocol for the oldest review was first published 20 years ago.

Over the years the reviews have progressively accumulated evidence leading to ever greater stability in their conclusions. 'Stable' is a publication flag that usually indicates that the results are unlikely to change with the inclusion of new studies, such is the certainty of the results. The influenza vaccine reviews present us with a partly different situation. Readers will notice important outcomes where we have little or no data. They may also see that for some measures of influenza and 'influenza-like illness' (ILI), we have low-certainty evidence. We have reached a point where the evidence is not showing anything different to what it has done for a number of years. We know with varying degrees of certainty about vaccination effects on influenza and ILI, but the gap in our understanding of how vaccines affect the consequences of influenza persist. For each review, the impact of single studies is documented in the summary table 1 "Studies included in the various versions of this review and their impact on our conclusions". This month the three reviews (https://www.cochrane.org/news/featured-review-three-updated-cochrane-reviews-assessing-effectiveness-influenza-vaccines) appear in their latest updated and stabilised format.[1,2,3] Whilst we do not believe that periodic updating will complete the picture, our decision to stabilise is conditional. The three reviews will not be updated again unless certain criteria are met.

First, a new trial that meets inclusion criteria becomes available. Few trials of interest have been conducted recently, as a comparison with an inactive control is considered by some to be unethical. In the elderly, the latest completed trial dates from nearly two decades ago. Our searches have failed to find relevant ongoing trials.

A second condition is the introduction of a new generation of vaccines, based on new technology. This is possible given that several new technologies are being developed, such as vaccines containing fragments of the haemagglutinin antigen "stalk" on the viral surface (so called stalk-specific vaccines).[4]

The third condition is more complex: the development and testing of a new causal paradigm for ILI and influenza. Currently, massive worldwide machinery is needed to produce new vaccines every year to address viral antigenic changes, and to address the poor persistence of the antibody response in individuals. However, the vaccination selection and production programmes are based on aetiological assumptions which are neither explanatory nor predictive, as shown in our reviews. Overall the largest dataset to have accumulated to date is from trials conducted in the population least likely to benefit from vaccines but most likely to produce immunity: healthy adults. In healthy adult trials a high serological response is matched by a very small clinical effect (71 healthy adults need to be vaccinated to prevent one of them experiencing influenza). This weak effect cannot be explained simply by the mismatch of vaccine antigens with wild virus ones. A larger effect is observed in children over the age of two (five children need to be vaccinated to prevent one case of influenza, although there is huge uncertainty around these estimates). There is little evidence on prevention of complications, transmission, or time off work. Other reviews have drawn similar conclusions.[5]

During stabilisation we updated the randomised evidence, but for the first time have decided against updating the large observational evidence base. The observational dataset still appears in the reviews, but only as a historical record of earlier versions. Observational studies were included in the reviews over a decade ago in the hope they could provide long-term and rare harms data and improve the external validity of the trial evidence. They turned out to be of such low quality that their conclusions were inconclusive or unreliable. The most important example is the case-negative study to assess influenza vaccine effectiveness *post hoc* (i.e. after an influenza season) by harvesting data from a surveillance programme. This study design, which is similar to a case-control study, selects influenza cases (cases of ILI which have tested positive for influenza) and controls (cases of ILI which have tested negative) and calculates the relevant odds ratio (OR) of exposure to that season's vaccine. An estimate of vaccine effectiveness is derived from this OR using a standard formula (vaccine effectiveness = 1 - OR%). However, despite their institutional popularity,[6,7] case-negative designs have limited public health significance because the design does not test field effectiveness, but, rather, laboratory efficacy of the vaccine (the capacity of the vaccine to generate a negative polymerase chain reaction (PCR) result). Both cases and controls are symptomatic, so any prevention is solely focused on PCR negativity. In addition, no useful public health absolute measures of effect can be derived (such as absolute risk reduction (ARR) and its reciprocal number needed to vaccinate to prevent one case (NNV)) because the background rates of infection and viral circulation are not part of the calculation of the estimates of effect. There are also problems with the mathematical assumptions made in this design (for details see the reviews). Case-negative studies are an illustration of the narrow and retrospective focus on influenza viruses at the expense of overall ILI - the

illness cluster of interest to patients and their clinicians. Retrospective calculation of relative estimates of laboratory efficacy can be of interest for future decisions on composition of vaccines, but their relevance to everyday decisions seems questionable.

The underlying assumption that influenza vaccination does not affect the risk of non-influenza is contradicted by a recent report from the follow up of a trial by Cowling et al.[8] In 115 participants, those who received trivalent influenza vaccines had higher risk of acute respiratory infection associated with confirmed non-influenza respiratory virus infection (RR, 4.40; 95% CI, 1.31–14.8) compared to placebo recipients. The agents were mainly rhinoviruses and coxsackie/echoviruses; ILI episodes occurred shortly after a peak of influenza activity.

Current yearly registration of candidate influenza vaccines is based on their ability to trigger a good antibody response. But antibody responses are poor predictors of field protection. This is another example of the use of surrogate outcomes in biomedicine, where effects on clinically important outcomes remain unmeasured or unproven from randomised trials: complications and death by influenza.

The simple answer is that we do not understand what the target is. What is the threat of influenza, and what can we ever expect of the vaccines?

The WHO Global Influenza Programme (http://www.who.int/influenza/surveillance_monitoring/en/) (GIP) with its backbone Global Influenza Surveillance and Response System (http://www.who.int/influenza/gisrs_laboratory/en/) (GISRS) is a complex network of 143 national reference centres and specialist laboratories in 113 states carrying out surveillance of circulating influenza viruses. GISRS was devised and developed to guide annual influenza vaccine production, and the emphasis is mainly on influenza viruses, their variants, and emerging strains.

However there is no reliable system to monitor and quantify the epidemiology and impact of ILI, the syndrome that presents clinically. Few states produce reliable data on the number of physician contacts or hospitalised cases due to ILI, and none tie these data to the proportion of ILI caused by influenza. We do not know for certain what the impact of ILI is, nor the impact of the proportion of ILI caused by influenza. Prospective studies apportioning positivity to the scores of viruses probably causing ILI are rare, as interest is focused on influenza. The standard quoted figure of 36,000 yearly deaths in the US is based on the “respiratory and circulatory deaths” category including all types of pneumonia, including secondary to meconium ingestion or bacterial causes. More recently, the US Centers for Disease Control and Prevention (CDC) have proposed estimates of impact ranging between 3,000 and 49,000 yearly deaths. When actual death certificates are tallied, influenza deaths on average are little more than 1,000 yearly (http://dspace.mit.edu/handle/1721.1/69811) . So, the actual threat is unknown (but likely to be small) and so is the estimation of the impact of vaccination.

The uncertainty over the aetiology of ILI, its capricious nature and the weak correlation between immunity and protection, point to possible causal or concurrent factors in the genesis of both ILI and influenza. In other words, virus positivity may only be one of the factors necessary for a case of influenza or ILI to manifest itself.

We await to see whether anyone has the interest or the courage to develop effective ways to control upper respiratory viral syndromes. Meanwhile our reviews will remain as a testimonial to the scientific failure of industry and governments to address the most important clinical outcomes for patients.

Abstract

IMPORTANCE—The Advisory Committee on Immunization Practices (ACIP) recommends the tetanus, diphtheria, and acellular pertussis (Tdap) vaccine for pregnant women during each pregnancy, regardless of prior immunization status. However, safety data on repeated Tdap vaccination in pregnancy is lacking.

OBJECTIVE—To determine whether receipt of Tdap vaccine during pregnancy administered in close intervals from prior tetanus-containing vaccinations is associated with acute adverse events in mothers and adverse birth outcomes in neonates.

DESIGN, SETTING, AND PARTICIPANTS—A retrospective cohort study in 29 155 pregnant women aged 14 through 49 years from January 1,2007, through November 15,2013, using data from 7 Vaccine Safety Datalink sites in California, Colorado, Minnesota, Oregon, Washington, and Wisconsin.

EXPOSURES—Women who received Tdap in pregnancy following a prior tetanus-containing vaccine less than 2 years before, 2 to 5 years before, and more than 5 years before.

MAIN OUTCOMES AND MEASURES—Acute adverse events (fever, allergy, and local reactions) and adverse birth outcomes (small for gestational age, preterm delivery, and low birth weight) were evaluated. Women who were vaccinated with Tdap in pregnancy and had a prior tetanus-containing vaccine more than 5 years before served as controls.

RESULTS—There were no statistically significant differences in rates of medically attended acute adverse events or adverse birth outcomes related to timing since prior tetanus-containing vaccination. *

*Check METHODS, Study Design, and EXCLUSIONS. Page 5.

	Time Since Prior Tetanus-Containing Vaccination, y		
Outcome	**<2**	**2–5**	**>5 (Control)**
Local reactions, rate/10 000 women	4.2	7.0	11.2
Adjusted risk ratio (95% CI)	0.49 (0.11–2.20)	0.77 (0.31–1.95)	1 [Reference]
P value	.35	.59	
Preterm delivery, %	6.6	6.4	6.8
Adjusted risk ratio (95% CI)	1.15 (0.98–1.34)	1.06 (0.94–1.19)	1 [Reference]
P value	.08	.33	
Small for gestational age, %	9.0	8.7	9.1
Adjusted risk ratio (95% CI)	0.99 (0.87–1.13)	0.96 (0.87–1.06)	1 [Reference]
P value	.88	.45	

CONCLUSIONS AND RELEVANCE—Among women who received Tdap vaccination during pregnancy, there was no increased risk of acute adverse events or adverse birth outcomes for those who had been previously vaccinated less than 2 years before or 2 to 5 years before compared with those who had been vaccinated more than 5 years before. These findings suggest that relatively recent receipt of a prior tetanus-containing vaccination does not increase risk after Tdap vaccination in pregnancy. *

*Check METHODS, Study Design, and EXCLUSIONS. Page 5.

Pertussis (whooping cough) is a vaccine-preventable illness that has been increasing in incidence over the past decade in the United States.[1–3] Neonates and infants are at increased risk of pertussis-related hospitalization and death compared with older children and adults. Many public health strategies have been recommended to decrease the burden of pertussis in neonates and infants.[4–6] Most recently, in 2012, the Centers for Disease Control and Prevention (CDC) Advisory Committee on Immunization Practices (ACIP) recommended tetanus, diphtheria, and acellular pertussis (Tdap) vaccination for all pregnant women during each pregnancy regardless of prior immunization status.[6]

However, few published studies have evaluated the safety of Tdap vaccine in pregnant women.[7–11] In these studies, Tdap vaccination during pregnancy has not been associated with an increased risk of spontaneous abortion, stillbirth, preterm delivery, low birth weight, neonatal complications, or congenital anomalies compared with unvaccinated pregnant controls. Additionally, 1 retrospective study showed that pregnant women vaccinated with Tdap who had received a prior Tdap vaccine within 5 years had no difference in neonatal outcomes compared with women receiving their first Tdap vaccine in pregnancy.[11]

Most safety studies on administering repeated doses of tetanus-containing vaccines are limited to nonpregnant individuals.[12–14] These studies have shown that intervals less than 5 years between tetanus-containing vaccines can be associated with increased local reactions and fever. Although these studies did not find an increased risk of Arthus reactions (severe dermal inflammation, endothelial damage, and vascular necrosis), this has been a concern with shortened intervals between tetanus vaccine doses.[12–14]

This study focused on determining whether there is association between receipt of Tdap vaccine during pregnancy administered in close intervals from prior tetanus-containing vaccinations and acute adverse events in mothers and adverse birth outcomes in neonates.

Methods

Study Population

The study protocol was reviewed and approved by institutional review boards at Emory University, the CDC, and the 7 Vaccine Safety Datalink (VSD) sites and was determined exempt from requiring participant consent. The study cohort included pregnant women enrolled in the VSD (Figure). The VSD is a collaborative project between the CDC and 9 integrated health care organizations.[15] The VSD includes data on more than 9 million individuals annually (approximately 3% of the US population), with an annual birth cohort of approximately 90 000. Data are collected from standardized files prepared at each site that contain individual demographic, enrollment, immunization, hospitalization, emergency department visits, and outpatient visits. For this study, 7 VSD sites contributed data: Group Health Cooperative (Washington), Kaiser Permanente Northwest (Oregon and Washington), Kaiser Permanente Northern California, Southern California Kaiser Permanente, HealthPartners (Minnesota), Marshfield Clinic (Wisconsin), and Kaiser Permanente Colorado. These sites were chosen because they contribute pregnancy data on a yearly basis. Although the majority of the VSD data comes from the 2 California sites, and thus the western United States, the demographic characteristics of the VSD population have been shown to be generally comparable with that of the entire US population.[16]

Study Design

We conducted a retrospective cohort study among pregnant women vaccinated with Tdap by evaluating medically attended acute adverse events (occurring in outpatient, inpatient, and emergency department settings) in mothers and adverse birth outcomes in their neonates. We compared adverse events between women receiving a prior tetanus-containing vaccine less than 2 years before and 2 to 5 years before with women who had received a prior tetanus-containing vaccine more than 5 years before (controls). We chose these comparisons based on intervals used in prior studies comparing acute adverse events following multiple tetanus-containing vaccines in nonpregnant individuals.[12–14] Prior vaccination status was irrespective of pregnancy status at the time of vaccination.

We identified pregnancies ending between January 1,2007, and November 15, 2013, in automated data using a validated pregnancy algorithm[17] that has been used in prior VSD pregnancy studies.[18,19] This pregnancy episode algorithm uses claims, administrative, and

birth data from the electronic medical record to identify pregnancies, pregnancy outcomes, and gestational age at pregnancy outcome, and has been shown to be accurate within 28 days in confirming the estimated pregnancy start date for 99% of live births and in confirming the pregnancy outcome date for 96% of live births.[17]

We included women aged 14 through 49 years who received Tdap vaccine during pregnancy and had continuous insurance coverage from 6 months prior to pregnancy to 6 weeks postpartum with no more than a 30-day gap in enrollment. We excluded women who had no documentation of prior tetanus-containing vaccines, women who received live vaccines during pregnancy, and women with a multiple gestation pregnancy. We also excluded pregnancies with non-live birth outcomes (stillborn, spontaneous abortion, therapeutic abortion, trophoblastic disease, and ectopic pregnancy) because we did not have the resources to access medical records to confirm the timing of these outcomes in relation to vaccination, which could result in inaccurate findings. Finally, we excluded all women who received non-Tdap tetanus-containing vaccines during pregnancy (ie, tetanus diphtheria [Td]).

We identified vaccinations using electronic medical record and insurance claims data that are captured in the standardized VSD vaccine file. We defined a vaccine administered during pregnancy as one given from 7 days after the woman's last menstrual period through 7 days before the date the pregnancy ended. We used these cutoffs to avoid misclassification of vaccines that might have been given prior to pregnancy or postpartum.[10,19]

Outcome Measures

We compared *International Classification of Diseases, Ninth Revision, Clinical Modification* (*ICD-9-CM*) codes for fever, local reactions (limb pain, limb swelling, cellulitis, lymphadenitis, and Arthus reaction), and allergic reactions (allergy, urti-caria, and anaphylaxis) occurring in intervals of 0 through 3 days and 0 through 7 days following Tdap vaccine, excluding duplicate diagnoses that had been given in the previous 30 days to capture incident cases associated with a health care visit. The day of vaccination was considered day 0, and we excluded any diagnoses on day 0 occurring in the outpatient setting, as they were likely present before the vaccination. As some allergic reactions may occur on day 0 in the outpatient setting, we performed a sensitivity analysis including diagnoses of allergic reactions in the outpatient setting on the day of vaccination. We compared the risk of incident cases of Guillain-Barré syndrome in the inpatient setting, using a 1-through 42-day time window following vaccination. We also examined the following adverse birth outcomes: preterm delivery (defined as gestational age <37 weeks), low birth weight (birth weight <2500 g), and small for gestational age (weight <10th percentile for gestational age and sex).[20]

Statistical Methods

We compared baseline characteristics between the 3 groups of pregnant women who received Tdap vaccine. We used χ^2 tests to compare categorical variables, and analysis of variance to compare continuous variables. We identified all adverse events using *ICD-9-CM* codes. We used log-binomial regression analysis to calculate the relative risks (RRs) for both

rare and non-rare events. Akaike Information Criterion measurements are included as assessments of model fit (eTable1 in the Supplement). We adjusted for differences in gestational age at time of vaccination and VSD site (Kaiser Permanente Northern California, Southern California Kaiser Permanente, or other site) when comparing acute events. When comparing birth outcomes, we also adjusted for maternal age, length of enrollment (in months) in the health plan prior to pregnancy, risk factors for pregnancy adverse events, pregnancy complications, and prenatal care utilization, because these are likely to independently affect birth outcomes. Prenatal care utilization was assessed using the Kotelchuck Adequacy of Prenatal Care Utilization Index, which takes into account the number of prenatal care visits from the time of the first prenatal care visit until delivery.[21] Comorbidities (asthma, diabetes, hypertension, and cardiovascular disease) and pregnancy complications were identified using *ICD-9-CM* codes. Only records that contained information on the neonate (ie, weight and gestational age) were used when analyzing birth outcomes. In addition, only vaccinations given prior to 37 weeks of gestation were included, so as to not bias the results for preterm delivery and low birth weight. All analyses were performed using SAS (SAS Institute), version 9.3.

We performed a priori power calculations based on an expected sample size of 24 000 women and determined that we had 80% or higher power to detect an RR greater than 2 for all of our birth outcomes. However, analyses for medically attended acute adverse outcomes, which are rare, were under-powered. To detect an RR greater than 2 for local reactions, 10 000 participants would be needed in each cohort; for fever, 37 000 participants; and for allergic reactions, 75 000 participants. We considered results to be statistically significant at an a error less than .05 using 2-tailed tests.

Results

From January 1, 2007, through November 15,2013, there were a total of 633 542 singleton pregnancies recorded in the VSD sites (Figure). After applying exclusion criteria, we identified 61 311 pregnancies in which a single Tdap vaccine was given. We excluded 32 156 pregnancies (52%) because there was no prior history of a tetanus-containing vaccine documented. Our final analytic data set included 29 155 pregnancies. Of these pregnancies, 4812 women (17%) had a prior tetanus-containing vaccine less than 2 years before, 9999 women (34%) 2 to 5 years before, and 14 344 women (49%) more than 5 years before (controls).

Among the 29 155 pregnancies ending from 2007 through 2013, the majority of Tdap vaccinations were administered from 2010 through 2013 (98.1%), and most were administered in 2013 (54.0%). In the overall cohort, Tdap was most often administered in the third trimester (67.4%). Fewer women received the vaccine in the second trimester (27.5%) and the first trimester (5.1%). Maternal age, length of enrollment, and gestational age at Tdap vaccination were significantly different in the 3 study groups ($P = <.001$) (Table 1). In addition, most pregnant women who received a prior tetanus-containing vaccine less than 2 years before (94%) and 2 to 5 years before (85%) their current Tdap vaccine had previously received Tdap (as opposed to a non-Tdap tetanus-containing vaccine) vs only 17% of controls ($P < .001$).

Acute Outcomes

Overall, acute adverse events after vaccination were rare (eTables 2–3 in the Supplement). There were no statistically significant differences in fever, allergic reactions, or local reactions among women who had received their prior tetanus-containing vaccine less than 2 years before and 2 to 5 years before compared with controls (Table 2). Fever beginning 0 through 3 days after vaccination occurred at a rate (per 10 000 women) of 2.1 in those who received Tdap and had a prior tetanus-containing vaccine less than 2 years before compared with 3.5 among controls (adjusted RR, 0.66 [95% CI, 0.07–5.77]; $P = .70$). Allergic reactions beginning 0 through 3 days after vaccination occurred at a rate (per 10 000 women) of 2.1 in women who received Tdap and had a prior tetanus-containing vaccine less than 2 years before (adjusted RR, 1.55 [95% CI, 0.13–18.45]; $P = .73$) and 1.0 in those receiving it 2 to 5 years before (adjusted RR, 0.71 [95% CI, 0.06–8.13]; $P = .78$) compared with 1.4 among controls. Local reactions beginning 0 through 3 days after vaccination occurred at a rate (per 10 000 women) of 4.2 in women who received Tdap and had a prior tetanus-containing vaccine less than 2 years before (adjusted RR, 0.49 [95% CI, 0.112.20]; $P = .35$) and 7.0 in those receiving it 2 to 5 years before (adjusted RR, 0.77 [95% CI, 0.31–1.95]; $P = .59$) compared with 11.2 among controls. There was no increased risk of allergic reactions based on the sensitivity analysis including outpatient diagnoses occurring on day 0 (eTable 4 in the Supplement). There were no cases of anaphylaxis, Arthus reactions, or Guillain-Barré syndrome following vaccination.

Birth Outcomes

There were no statistically significant differences in adverse birth outcomes among women who had received their prior tetanus-containing vaccine less than 2 years before and 2 to 5 years before compared with controls (Table 3). Preterm delivery occurred in 6.6% of women who received Tdap and had a prior tetanus-containing vaccine less than 2 years before (adjusted RR, 1.15 [95% CI, 0.98–1.34]; $P = .08$) and 6.4% of those receiving it 2 to 5 years before (adjusted RR, 1.06 [95% CI, 0.94–1.19]; $P = .33$) compared with 6.8% of controls. Low-birth-weight delivery occurred in 4.7% of women who received Tdap and had a prior tetanus-containing vaccine less than 2 years before (adjusted RR, 1.10 [95% CI, 0.92–1.32]; $P = .31$) and4.7% of those receiving it2to5 years before (adjusted RR, 1.03 [95% CI, 0.89–1.18]; $P = .72$) compared with 5.1% of controls. Small for gestational age delivery occurred in 9.0% of women who received Tdap and had a prior tetanus-containing vaccine less than 2 years before (adjusted RR, 0.99 [95% CI, 0.87–1.13]; $P = .88$) and 8.7% of those receiving it2to5 years before (adjusted RR, 0.96 [95% CI, 0.87–1.06]; $P = .45$) compared with 9.1% of controls.

Discussion

To our knowledge, this is the first study to evaluate medically attended acute adverse outcomes in mothers following Tdap vaccine in pregnancy looking specifically at intervals since receipt of prior tetanus-containing vaccinations. We did not find any differences in acute events in the mothers or adverse birth outcomes in neonates when comparing women who were vaccinated with Tdap during pregnancy regardless of the length of time since a prior tetanus-containing vaccine. Our findings should reassure patients and clinicians who

might be hesitant to give Tdap vaccine to pregnant women who recently received a Tdap or other tetanus-containing vaccination.

Our findings are similar to another retrospective cohort study evaluating women receiving Tdap in pregnancy who had a prior pregnancy with Tdap vaccine administered within 5 years compared with multiparous women with no prior Tdap vaccine in pregnancy.[11] This study found no difference in gestational age at delivery, stillbirth, major malformations, neonatal care admissions, ventilation requirements, and neonatal death, whereas ours focused on preterm delivery, small for gestational age, and low birth weight.* The prior study did note a small increase in average birth weight of neonates of women receiving multiple Tdap vaccines. Our study did not compare actual birth weights, but rather compared the presence of low-birth-weight (<2500 g) delivery, and did not find a statistically significant difference. *This was a much smaller study and did not consider the fact that pregnant women in the group declining Tdap vaccination may have chosen to do so because they had high risk pregnancies. "...the cohort of women who declined vaccination suggests that Tdap vaccine nonacceptance may identify a high-risk group..." Our findings contrast with some studies in other populations that suggest an increased risk of adverse events when tetanus-containing vaccines are given at short intervals, most of which evaluated differences in solicited adverse events.[12–14] In 2006, a clinical trial of 7156 children found that Tdap vaccine was well tolerated when given at intervals as short as 18 months since prior tetanus-containing vaccines; however, there was an increase in solicited injection site swelling and erythema in participants who received a tetanus-containing vaccine more recently.[12] A VSD retrospective cohort study of 436 828 Td vaccinations demonstrated that medically attended local reactions, including cellulitis, were more common among persons who received a Td-containing vaccine within the last 5 years compared with a longer interval.[13] Another study assessed safety in 4524 Tdap-vaccinated health care workers during a pertussis outbreak in New England.[14] Overall, there was no difference in the rates of solicited moderate or severe injection site reactions, but there was an increase in redness, swelling, and subjective fever among patients who had received their prior Td-containing vaccine less than 2 years earlier. Among 20 pregnant women included in that study, only 1 person reported severe swelling and 2 reported feeling feverish without documented fever. All symptoms in these pregnant women resolved without treatment, and all neonates were born at term with normal newborn evaluations. None of the pregnant women had received a prior tetanus-containing vaccine 2 years before their Tdap vaccination.

One explanation of the apparent paucity of acute adverse events with short tetanus vaccination intervals in our study could be related to shifts in immunological responses that occur during pregnancy.[22] These include shifts in humoraland cellular-mediated immunity and natural killer cells that occur to protect the fetus from harm. Among other changes, there may be less inflammation that occurs in response to vaccinations, which may result in fewer adverse events following multiple tetanus-containing vaccinations given in close proximity. Another explanation could be that we relied exclusively on medically attended adverse events, which are rare, whereas the majority of prior studies included solicited adverse events. Therefore, milder reactions that do not come to medical care might not have been included.

Our study has some limitations. We had limited power for the acute adverse events analysis. However, the rates of acute adverse events were generally not more common in pregnant women who had more recent tetanus-containing vaccinations. We also excluded women with no prior documented tetanus-containing vaccination, which comprised 52% of the Tdap-vaccinated cohort, to reduce misclassification. Although it is unlikely that these women never received a tetanus-containing vaccine in the past, this exclusion allowed for more conservative estimates of risk as the cohorts were not diluted with women that were potentially previously unvaccinated. There is the potential for some confounding due to differences in the type of vaccine received because the majority of the women in our study who were vaccinated with tetanus-containing vaccines less than 2 years before received Tdap and those vaccinated more than 5 years before had previously received Td. Additionally, we did not review medical charts to validate the adverse events, which would correct for any potential overestimation of the rates of acute reactions following Tdap in pregnancy. Although this is important, we would expect any resulting misclassification bias to be nondifferential, and not to affect our overall results. Finally, the VSD population is an insured population, and these findings may not be generalizable to the entire US population. However, demographic characteristics of the VSD population, including race, ethnicity, income, and education, have been shown to be generally comparable with the population of the United States.[16]

Future studies are needed to determine if there are differences in other important adverse pregnancy outcomes, such as stillbirth and spontaneous abortion, when Tdap is given in pregnancy in close intervals from prior tetanus-containing vaccines.

Conclusions

Among women who received Tdap vaccination during pregnancy, there was no increased risk of acute adverse events or adverse birth outcomes for those who had been previously vaccinated less than 2 years before or 2 to 5 years before compared with those who had been vaccinated more than 5 years before. These findings suggest that relatively recent receipt of a prior tetanus-containing vaccination does not increase risk after Tdap vaccination in pregnancy.

Abstract

BACKGROUND: The Advisory Committee on Immunization Practices currently recommends pregnant women receive influenza and tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis (Tdap) vaccines. There are limited studies of the long-term safety in infants for vaccines administered during pregnancy. We evaluate whether maternal receipt of influenza and Tdap vaccines increases the risk of infant hospitalization or death in the first 6 months of life.

METHODS: We included singleton, live birth pregnancies in the Vaccine Safety Datalink between 2004 and 2014. Outcomes were infant hospitalizations and mortality in the first 6 months of life. We performed a case-control study matching case patients and controls 1:1 and used

conditional logistic regression to estimate odds ratios for maternal exposure to influenza and/or Tdap vaccines in pregnancy.

RESULTS: There were 413 034 live births in our population. Of these, 25 222 infants had hospitalizations and 157 infants died in the first 6 months of life. We found no association between infant hospitalization and maternal influenza (adjusted odds ratio: 1.00; 95% confidence interval [CI]: 0.96–1.04) or Tdap (adjusted odds ratio: 0.94; 95% CI: 0.88–1.01) vaccinations. We found no association between infant mortality and maternal influenza (adjusted odds ratio: 0.96; 95% CI: 0.54–1.69) or Tdap (adjusted odds ratio: 0.44; 95% CI: 0.17–1.13) vaccinations.

CONCLUSIONS: We found no association between vaccination during pregnancy and risk of infant hospitalization or death in the first 6 months of life. These findings support the safety of current recommendations for influenza and Tdap vaccination during pregnancy.*

*Methods:

This study removed all cases of:
- Hospitalization or death of the infant during pregnancy or birth.
- Pre-term birth before 34 weeks.
- Birth defects in infants.
- Perinatal complications.

Study also does not compare outcomes to outcomes of unvaccinated infants.

The Advisory Committee on Immunization Practices currently recommends 2 vaccines to be given during each pregnancy; influenza vaccine has been recommended at any time during pregnancy since 2004 to prevent maternal influenza disease and complications[1] and tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis (Tdap) vaccine has been recommended during each pregnancy since 2012, with a preference for administration between 27 and 36 weeks' gestation, to protect infants from pertussis disease.[2] Given the relative proximity of an immunization administered during pregnancy to a potential infant hospitalization or death, an observed temporal association with maternal influenza or Tdap vaccine during pregnancy and infant death or hospitalization may raise concerns about a possible causal relationship.

Both pertussis and influenza infections are associated with hospitalizations and fatalities in infants, and severity is highest before infants are eligible for the respective vaccines. Approximately half of infants <4 months of age with pertussis require hospitalization, and the majority of deaths from pertussis occur in these infants.[3] In 2014, the US pertussis case rate in infants <6 months of age was 169 per 100 000 infants.[4] Furthermore, there were 8 deaths in infants <3 months of age and 1 death in infants 3 to 11 months of age out of 13 total deaths from pertussis in all age groups in 2014. Similarly, infants are at high risk of hospitalization and death from influenza. The US influenza hospitalization rate ranges from 1.8 to 7.2 per 1000 in infants <6 months of age.[5] For the 2013–2014 influenza season, there were 96 laboratory-confirmed, influenza-associated pediatric deaths, 18 of which occurred in children aged <6 months.[6] Maternal immunization with influenza and Tdap vaccines allows for passive antibody transfer and protection to infants for the respective diseases when they are most vulnerable.[1,2,7]

In 2015, the infant (≤12 months) mortality rate in the United States was 589.5 per 100 000 live births,[8] and the leading causes of infant deaths were (1) congenital malformations, deformations, and chromosomal abnormalities; (2) disorders related to low birth weight and short gestation; and (3) sudden infant death syndrome. In 2010, the leading causes of hospitalizations in infants ≤12 months were (1) acute bronchitis (238 per 10 000 population), (2) jaundice (104 per 10 000 population), and (3) pneumonia (56 per 10 000 population).[9] Although there have been reassuring safety data for influenza and Tdap vaccines in which maternal acute events, pregnancy complications, and birth outcomes were

evaluated,[10–19] there have been limited safety studies beyond the immediate neonatal period.[20–24] Vaccine safety continues to be a primary reason why providers and patients choose not to vaccinate during pregnancy.[25–27] Although the biologic plausibility is unclear for the association of maternal vaccination and infant hospitalization or death, there may be concerns of long-term effects on infants after any pregnancy exposure. In this study, we evaluate whether maternal receipt of influenza and Tdap vaccines increases the risk of hospitalization or death in US infants in the first 6 months of life.

METHODS

Study Population

The Vaccine Safety Datalink (VSD) is a collaboration between the Centers for Disease Control and Prevention and 8 integrated health care systems (sites) and includes vaccination and health care data on ~10 million persons per year.[28] In addition, the VSD includes data on ~ 125 000 pregnant women annually.

We used data on pregnant women from 5 VSD sites with available data that comprise over 90% of the VSD population: Kaiser Permanente Northern California (Oakland, CA), Kaiser Permanente Southern California (Pasadena, CA), Kaiser Permanente Colorado (Denver, CO), Marshfield Clinic Research Foundation (Marshfield, WI), and Kaiser Permanente Northwest (Portland, OR).

We used the validated VSD Pregnancy Episode Algorithm to identify pregnant women.[29] The Pregnancy Episode Algorithm uses comprehensive electronic medical record and administrative databases (including diagnosis and procedure codes, laboratory tests, pharmacy records, and imaging procedures) to identify pregnancies, pregnancy outcomes, and pregnancy start and end dates, and it is able to link pregnant women to their infants. We included women from the VSD with pregnancies ending in a live birth between January 1, 2004, and June 30, 2014. We required pregnant women to be enrolled at a VSD site for the duration of the pregnancy episode and to have at least 1 prenatal care visit. To increase completeness of data, infants of these pregnant women were required to have a birth record and to have VSD site enrollment until 6 months of life or until the time of death. We excluded pregnancies in which a live vaccine was administered because live vaccines are contraindicated in pregnancy. We also excluded infants of multiple gestation pregnancies, infants born before 34 weeks' gestation, and infants with major birth defects because these infants are at a higher risk of hospitalization and death. Furthermore, we excluded all infants who died during their delivery hospitalization because cause of death in these infants is often a perinatal complication (such as placental abruption) that would likely be unrelated to maternal vaccination.* Additionally, infants who die during the birth hospitalization may be less likely to be enrolled in the VSD and captured in our data. We also excluded infants with external causes of death (*International Classification of Diseases, 10th Revision* [ICD-10] codes S00-T98 and V00-Y98) and infants with external causes of hospitalizations (*International Classification of Diseases, Ninth Revision* [ICD-9] codes 800–999, E800-E999) due to injury and poisonings because these are unlikely to result from a maternal vaccination. ICD-10 coding was not available for hospitalization diagnoses in the United States during the time of this study.

They are admitting that the Vaccine Safety Datalink is not capturing data on infants who die during the birth hospitalization.

*No research to support this statement.

Case-Control Matching

Among infants meeting inclusion criteria, those infants with hospitalizations or deaths within the first 6 months of life were included in this analysis. Respiratory hospitalization case patients were a subset of hospitalization case patients defined by any respiratory ICD-9 code (033, 460–488, 491–496, 510–519) associated with a hospitalization in the first 6 months of life. For infants with >1 hospitalization, the first hospitalization was selected for each category (ie, first all-cause hospitalization, first respiratory hospitalization). Furthermore, an infant could be included as a death case patient and hospitalization case patient if the infant was hospitalized and later died. In the VSD, deaths are identified from state death records, electronic medical records, and administrative sources, and there is approximately a 1-year lag from the time of death to the availability of state death records. Because of lag time in the death data, we evaluated deaths occurring from January 1, 2004, to December 31, 2013, and hospitalizations from January 1, 2004, to December 31, 2014. Matched controls for the infant mortality analysis were selected among infants in the study who survived the first 6 months of life. Matched controls for the infant hospitalization and respiratory hospitalization analyses were selected from infants without death or hospitalization in the first 6 months of life. All infant controls were required to have at least 1 diphtheria-tetanus-acellular pertussis (DTaP) vaccine recorded between 6 weeks and 6 months of age to ensure infants were accessing the health care system. We matched case patients and controls 1:1 using optimal matching.[30] Case patients and controls were matched on the basis of VSD site, birth month and year (within 1 month), and gestational age groups of late preterm (34–36 weeks), term (37–41 weeks), and postterm (42–44 weeks). With our optimal matching, we successfully found controls for 100% of our case patients by using these parameters.

Vaccinations

The exposure of interest was maternal vaccination with any influenza and/or Tdap vaccines during pregnancy. A vaccine during pregnancy was defined as one given from 7 days after the pregnancy start date to 7 days before the pregnancy end date. These time windows were chosen to avoid including exposures to vaccinations given before or immediately after pregnancy. We stratified vaccine exposures as any influenza vaccine (with or without Tdap), any Tdap vaccine (with or without influenza), and both influenza and Tdap vaccines in the same pregnancy. In our evaluation of maternal influenza vaccine, we also repeated our analysis limiting outcomes to events occurring during the influenza season (October through May), to ascertain any protective findings that may be more evident when influenza virus is circulating. We also did a sensitivity analysis stratifying our exposure by influenza vaccine only and Tdap vaccine only to see if our results would differ by limiting our exposure groups.

Statistical Analysis

We measured rates of influenza and Tdap maternal vaccination in our study cohort from 2004 to 2013. We also measured trends of infant deaths and hospitalizations during this same time period to look for any ecological associations between maternal vaccination and our infant outcomes. For our main analysis, we performed a conditional logistic regression

analysis to estimate the odds of maternal vaccination in matched case patients and controls. In our analysis, we determined a priori to include the following potential confounders from electronic VSD data sources[28]: Kotelchuck Adequacy of Prenatal Care Index,[31] race and ethnicity (non-Hispanic African American or American Indian versus other races and ethnicities), maternal age, pregnancy complications and maternal comorbidities (hemorrhage, hypertensive disorders, renal disease, diabetes, thyroid disease, cardiovascular disease, epilepsy), smoking during pregnancy (yes, no, or unknown), infant DTaP exposure before outcome (or index date in matched controls), duration of birth hospitalization in days, and gestational age at delivery in weeks.

We also reviewed medical records of infants with respiratory related deaths (ICD-10 codes: A37, J00–J99). We reviewed clinical information relating to a potential influenza- or pertussis-related cause of death and laboratory data in the 2-week period preceding death. For influenza laboratory data, we looked for positive influenza A or B rapid antigen, polymerase chain reaction (PCR), viral culture, and direct fluorescent antibody test results in all respiratory death case patients. For pertussis, we looked for positive *Bordetella pertussis* PCR and culture test results for any death case patient with the ICD-10 code A37 (whooping cough).

We determined a priori that with an expected average exposure rate of 15% for both vaccines throughout the study period,[32–34] we would need at least 840 case patients to have 80% power to detect an odds ratio of 1.5. The protocol for this study was approved by the Centers for Disease Control and Prevention Institutional Review Board and institutional review boards at each of the participating VSD sites. All analyses were conducted by using SAS version 9.3 (SAS Institute, Inc, Cary, NC).

RESULTS

During our study period, we identified 500 447 pregnancies ending in a live birth that met enrollment criteria. We excluded 87 413 (17.5%) because of maternal or infant factors (Fig 1). Of the remaining 413 034 infants, 25 222 infants had 1 or more hospitalizations and 157 infants died. Of the hospitalized infants, 4644 (18.4%) had a respiratory cause for their hospitalization; 105 (2.2%) of these infants had an influenza ICD-9 code (487, 488), and 137 (3%) had a pertussis ICD-9 code (033.0, 033.9). Of the deaths, 14 (9%) had a respiratory cause of death; however, none of these deaths were considered to have been caused by influenza or pertussis infections on the basis of our laboratory and medical record review. Of the 157 infants that died, the age at death ranged from 1 to 180 days with a mean of 61 days and a median of 51 days. The most common causes of death were unknown causes (32%), sudden infant death syndrome (21%), and certain conditions originating in the perinatal period (17%).

We analyzed overall trends of influenza and/or pertussis vaccination in pregnancy and trends of infant hospitalization and mortality in our study population from 2004 to 2013 (Fig 2). From 2004, there was an increase in maternal influenza vaccination, which became more dramatic in 2009 after the H1N1 influenza pandemic. Maternal Tdap vaccination increased starting in 2010 when California recommended pregnant women to receive Tdap in

pregnancy in response to the 2010 statewide pertussis epidemic.[35] There was another increase in Tdap vaccination in 2012 after the most recent Advisory Committee on Immunization Practices recommendation to administer Tdap vaccination in every pregnancy.[2] We observed no increase in the infant hospitalization rate or infant mortality rate during the same time period.

We matched case patients with eligible controls and compared characteristics between these groups (Table 1, Supplemental Table 3). Infants who were hospitalized were more likely to have mothers with pregnancy complications, less likely to be delivered by cesarean delivery, and less likely to be of African American non-Hispanic or American Indian race. Mean maternal age, gestational age at delivery, and length of birth hospitalization were statistically significantly different between the groups but not clinically different. Infants who died were similar to matched controls.

In our adjusted analysis, we found no significant association between infant hospitalization or death in the first 6 months of life and receipt of maternal influenza and/ or Tdap vaccines and no significant association between infant hospitalization from respiratory causes and maternal influenza vaccine (Table 2). However, the odds of maternal Tdap vaccination was significantly lower among infants with hospitalizations because of respiratory causes (adjusted odds ratio: 0.79; 95% confidence interval [CI]: 0.67–0.94; $P = .007$) compared with controls without hospitalization. Furthermore, when evaluating infant hospitalizations and death occurring during periods of influenza virus circulation (October through May) and peak influenza virus circulation (November through February), we found no association with maternal influenza vaccine exposure (data not shown). When limiting our exposure groups to women receiving influenza vaccine without Tdap vaccine and Tdap vaccine without influenza vaccine, our results were similar to our main analysis (Supplemental Table 4).

DiSCUSSiON

In our study of maternal influenza and Tdap vaccines, we found no increased risk of infant all-cause hospitalizations, hospitalizations from respiratory causes, or all-cause mortality in the first 6 months of life. Our study helps strengthen the growing evidence of long-term safety of vaccination in pregnancy for infants.

Our findings are similar to other studies that have evaluated infant mortality and morbidity after maternal vaccination in pregnancy, most of which have evaluated the safety of adjuvanted H1N1 influenza-containing vaccines. Studies of short-term infant mortality in the first 7 days of life,[20] growth and development and health care visits for infections in the first year of life,[23] early neonatal or childhood death,[22] and childhood hospitalization rates,[21] have not found an increased risk of these outcomes in children of women who received adjuvanted H1N1 influenza–containing vaccines in pregnancy. Unlike these previous studies, however, our study included women who received any type of influenza vaccine, none of which contain adjuvants in the United States, and we found similar results.

Our findings are also consistent with studies in which researchers have evaluated infant mortality and morbidity after Tdap vaccination in pregnancy. These researchers have

evaluated neonatal mortality,[10,36] NICU admissions,[37] length of hospitalization, ventilation requirement, intraventricular hemorrhage, transient tachypnea of the newborn, neonatal sepsis, pneumonia, respiratory distress syndrome, and convulsions.[36,38] There were no differences in outcomes between infants of Tdap-vaccinated and unvaccinated mothers in these studies. Our study included a longer follow-up period than these previous studies and still showed no increased risk of infant mortality or hospitalization after maternal Tdap vaccination.

Other long-term outcomes that have previously been studied after maternal Tdap vaccination include childhood development scores at 13 months of life,[13] infant growth up to 5 to 7 months of age,[24] and complex chronic conditions at 12 months of age.[17] The researchers for these studies did not find an increased risk of these infant outcomes after maternal Tdap vaccination during pregnancy. Our study managed a larger number of infants and had similar findings to these studies, further demonstrating long-term safety in infants of Tdap vaccine exposure in pregnancy.

We did find a protective association between maternal Tdap during pregnancy and infant respiratory hospitalizations, which is consistent with results of other published studies that have looked at infant pertussis as an outcome.[7,39–42] However, only 3% of infants hospitalized for respiratory causes had a pertussis ICD-9 code. This could indicate that infants with pertussis are not being appropriately diagnosed and tested.[43] It is also possible that other factors (eg, the healthy adherer effect[44] and other differences in people who choose vaccination and those who do not) are contributing to this finding.

This study does have some limitations. The VSD captures data on an insured population, which could translate to better health outcomes than the general population. Additionally, VSD has a high rate of women with adequate prenatal care on the basis of the Kotelchuck index, which can translate to better infant outcomes.[31] A recent study has revealed that despite being a fully insured population, the VSD is comparable to the total US population on many important demographic factors.[45] Moreover, the VSD population size is large, and even groups that typically comprise a smaller proportion of insured populations (ie, lower income populations) still have a substantial (>2 million individuals) presence in the VSD. There may have been bias related to requiring controls to have a DTaP vaccine record to be included in the study. We did this to ensure we had access to health care utilization data to avoid misclassifying case patients as controls. To look for bias, we repeated our analysis of hospitalizations requiring case patients to have a DTaP vaccine (98.0% of case patients) and found similar results to our main findings. We looked at broad safety outcomes (hospitalizations, respiratory hospitalizations, and deaths) and may not capture true increases in a specific outcome, if such an association was present. We relied on vaccination data from our VSD electronic data files and may not have captured vaccines in pregnancy occurring outside the health care system. However, previous internal work looking at influenza vaccination in pregnancy revealed that the VSD vaccine files are over 98% complete in capturing these data (J. Donahue, DVM, PhD, unpublished observations). We did not evaluate the risks of infant hospitalizations and mortality in multiple gestation infants, very preterm infants, and those with major birth defects because these infants are at a much higher risk of the outcomes we studied; therefore, our results are not generalizable to these

populations. Finally, we were sufficiently powered for our outcomes of hospitalizations and hospitalizations from respiratory causes but underpowered for the outcome of death.

This is the first study in which infant hospitalizations and mortality in the first 6 months of life after maternal influenza vaccine and Tdap vaccines are evaluated. In this large case-control study, we found no increased risk of infant hospitalization and death after vaccination in pregnancy.

Our findings support the safety of influenza and pertussis vaccinations during pregnancy for infants of vaccinated mothers.

WHAT'S KNOWN ON THIS SUBJECT:

Influenza and tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccines are recommended in pregnancy. Although there is evidence that these vaccines are safe in pregnant women, there are limited long-term data on infants born to mothers vaccinated during pregnancy.

WHAT THIS STUDY ADDS:

Influenza and tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccines in pregnancy are not associated with an increased risk of hospitalization or death in infants. Our findings contribute to the knowledge of the long-term safety of vaccination during pregnancy.

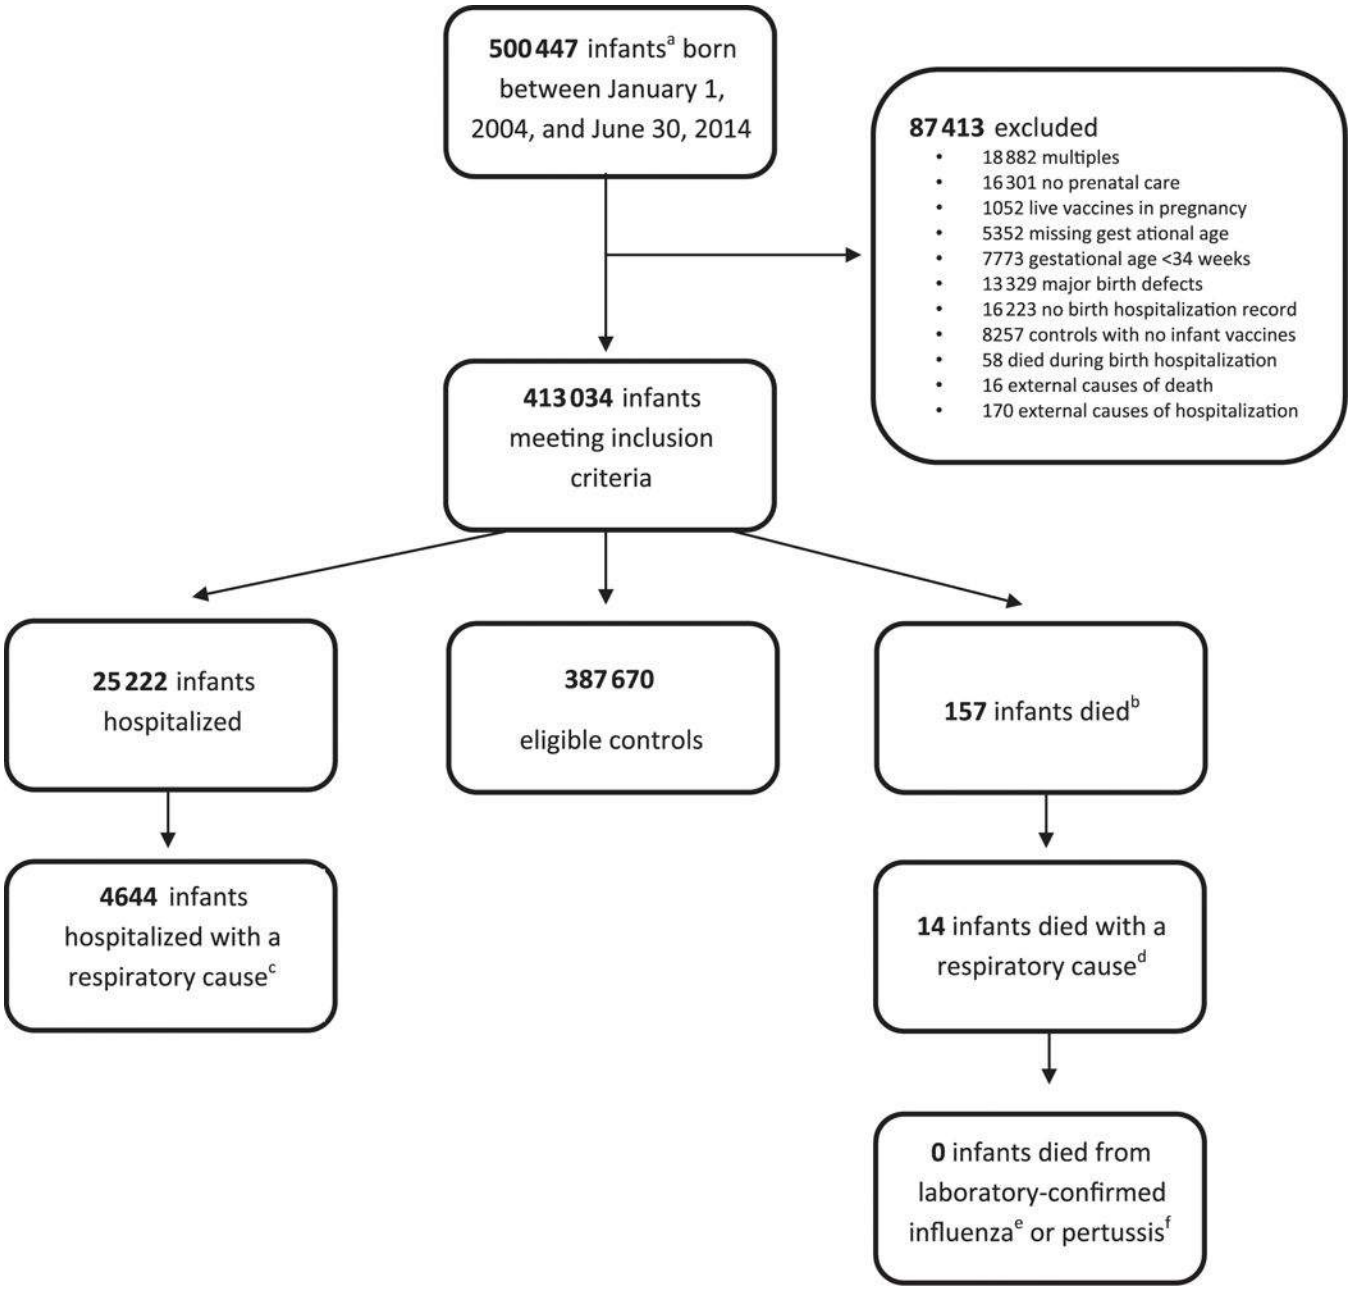

FIGURE 1.

Study population of infants with hospitalization or death in the first 6 months of life in the VSD, 2004–2014. The Present Status of Polio Vaccines.

Author(s) : RATNER, H., Moderator; COX, H. R.; GREENBERG, B. G.; KLEINMAN, H.; MEIER, P., Panelists

Journal article : Illinois Medical Journal 1960 Vol.118 No.2 pp.19 pp.

Abstract : A panel discussion on the present status of poliovaccines was held in Chicago on May 26th, 1960. 2 of the panellists, Dr. Ratner and Professor Meier, have been critics of Salk poliovaceine since its inception. Professor Greenberg and Dr. Kleinman have been concerned with the evaluation of poliovaceine effectiveness and Dr. Cox is responsible for the development of attenuated polio-virus vaccine. Kleinman has also been concerned with field trials of Lederle attenuated poliovaceine. The burden of the argunient is that killed poliovaceine has been a failure and that a change to a living vaccine should be made.

Ratner notes that poliomyelitis incidence has increased from the 1957 level in 1958 and 1959, and that substantial numbers of cases occur in the triply vaccinated. Greenberg points out some fallacies in the assessment of poliovaceine effectiveness. First, the requirements have altered to increase safety but it is thought that polio-vaccine potency decreases following the introduction of a second filtration step. [In the reviewer's experience of making killed vaccine it is clear that the quality of the filtration vitally affects safety but that with suitable precautions no potency need be lost.] The report of the Poliomyelitis Surveillance Unit of December 7th, 1955, is severely criticized because the numbers of children were taken from the 1950 census and no allowance was made for increases in the population. Also, children were considered as vaccinated regardless of whether they were vaccinated early or late in the year. This diminishes the rate in the vaccinated owing to swelling the vaccinated population with those who were vaccinated late in the year after having escaped clinical infection earlier. Differences in diagnostic criteria for non-paralytic and paralytic cases introduced as a result of the 1954 killed polio-vaccine trial are thought to be the major cause of the fall in incidence of reported poliomyelitis m 1957. [Most analyses of killed poliovaceine effectiveness allowing for these factors have showed it to be at least 80% effective.

Kleinman, who had previously estimated killed polio-vaccine to be very effective, is now dubious because of the increase in numbers of paralytic poliomyelitis. He confesses himself unable to decide whether the vaccine is or is not effective.

Meier reiterates his early fears about killed poliovaceine safety and the adequacy of the tests. He is uneasy about the propaganda effort to promote killed polio-vaccine. Experts, he contends, have doubts but in the newspapers the killed vaccine is represented as safe and very effective.

Meier reiterates his early fears about killed poliovaceine safety and the adequacy of the tests. He is uneasy about the propaganda effort to promote killed polio-vaccine. Experts, he contends, have doubts but in the newspapers the killed vaccine is represented as safe and very effective.
Cox and Kleinman describe the development and use of attenuated poliovaceine mainly in Latin America and Minnesota. They believe the vaccine to be safe and effective in producing antibodies and therefore most likely to be effective in preventing poliomyelitis.
Ratner, summing up, concludes that, if killed polio vaccine is safe and highly effective, licensing of living vaccine is not urgent. The panel's view is that this proposition is not proven and that a living vaccine is an urgent necessity.
[The failure of killed poliovaceine has mainly been due to failure to achieve satisfactory acceptance of the vaccine. It is hoped that this problem will be overcome by an oral vaccine. One argument used in favour of living vaccine is the uniform satisfactory results with living vaccines in the veterinary field. A review by PRIER, *J. Amer. Vet. Med. Ass.*, 1960, v. 137, 577, is not quite so enthusiastic.] *A. J. Beale.*

Dr. Jonas E. Salk injects a volunteer with his vaccine in 1954 field trials. Controversial from the first, the Salk vaccine is still a topic hotly debated.

The Truth About

Do Salk Shots Really Prevent Polio? Should We Keep Using Salk Inoculations? How Good Are the New Oral Vaccines? Here Are the Facts

By Joan Beck

BEHIND GLOWING reports of the Salk polio vaccine's success and even rosier predictions about the new, live, oral Sabin vaccine rages a storm of medical controversy that seldom reaches the ears of parents.

Many serious criticisms have been leveled at the Salk vaccine. These are now being acknowledged—at least indirectly—in announcements praising and promoting the new oral vaccines.

Yet all is not yet sweetness and accord among developers of the live, oral vaccines, either. At least three different types have been developed and—according to their producers—proved safe and effective in tests, chiefly in foreign countries, but also in the United States.

One of these new oral vaccines, developed by Dr. Albert Sabin with National Foundation research funds, has been OK'd by the United States public health service for manufacture. But there are problems remaining to be solved in its production and, according to a committee of experts headed by Dr. Roderick Murray of the National Institute of Health, dangers to be considered in its use by the general public (altho it has been given to a reported 77 million Russians and to at least 300,000 Americans. Russian Prof. Mikhail Chumakov, who directed a two year program of inoculation with the Sabin vaccine, says he is convinced polio epidemics have been eliminated in the Soviet Union). Licensing is not expected until this spring. Quantities of the vaccine are not expected to be available for community-wide use until November.

"Both 'live' (Sabin) and 'killed' (Salk) polio-virus vaccines will be needed to combat poliomyelitis in the near future, United States public health officials declared at the A. M. A. clinical meeting," the Journal of the American Medical association reported in December, 1960. "The new oral poliomyelitis vaccine developed by Dr. Albert Sabin and approved for future use in this country will not be the complete solution as far as can be predicted now, the public health service experts said."

Evaluating the true effectiveness of the Salk vaccine and the new oral vaccines has been difficult for several reasons. Polio is a relatively rare disease in the United States. Because so few persons get it in its paralyzing form, success of an immunizing agent is hard to determine.

The definition of polio also has changed in the last six or seven years. Several diseases which were often diagnosed as polio are now classified as aseptic meningitis or illnesses caused by one of the Coxsackie or Echo viruses. The number of polio cases in 1961 cannot accurately be compared with those in, say 1952, because the criteria for diagnosis have changed.

Even the Salk vaccine itself is not a constant, standard product. Since the first field trials of 1954, the vaccine has been changed several times. The first alterations were aimed at increasing the vaccine's safety by changing the method of killing the polio virus and by adding an extra filtration step. Newer changes are intended to increase the vaccine's effectiveness. The success of the Salk vaccine necessarily varies, depending upon which Salk vaccine is being considered.

Ever since the public was first informed about the Salk vaccine in the Francis report of April 12, 1955, the National Foundation has praised its effectiveness and urged parents to have themselves and their children vaccinated. Altho some physicians remained skeptical about the original theories behind the vaccine, about the techniques used in its evaluation, and about its success in combating polio, these objections seldom reached the general public. With the resurgence of paralytic polio in 1958 and 1959, the criticisms increased.

These views were summed up by five experts in a panel discussion on the "Present Status of Polio Vaccines" presented before the Illinois State Medical society in Chicago, in May, 1960, and published in the August and September issues of the Illinois Medical Journal. To make parents aware of the controversy about the Salk vaccine and the problems involved in developing an effective oral vaccine against polio, here is a report of that discussion:

Moderator of the panel was Herbert Ratner, M. D., director of public health in Oak Park, and associate clinical professor of preventive medicine and public health, Stritch School of Medicine, Chicago.

Dr. Ratner noted the upward trend in polio, particularly in the paralytic form, in the United States during 1958 and 1959. He quoted Dr. Alexander Langmuir, in charge of polio surveillance for the United States public health service, as saying this resurgence is "cause for immediate concern."

"In the fall of 1955, Dr. Langmuir had predicted that by 1957 there would be less than 100 cases of paralytic polio in the United States," commented Dr. Ratner. "Four years and 300 million doses of Salk vaccine later, we had in 1959 approximately 6,000 cases of paralytic polio, 1,000 of which were in persons who had received three and more shots of Salk vaccine. Salk vaccine hasn't lived up to expectations."

Dr. Sabin says the number of cases in 1960 was less than in 1959, but that 23 per cent are now occurring in persons who have had three or more doses of Salk vaccine.

Dr. Ratner next reviewed some basic facts about polio. Paralytic polio occurs in cycles and was in a natural decline when the Salk vaccine was introduced in 1955, he pointed out.

Prior to the introduction of the Salk vaccine, the National Foundation defined an epidemic as 20 or more cases of polio per year, per 100,000 population. Now, an epidemic is defined as 35 cases per year per 100,000. This change has resulted in a statistical —but not necessarily a real—drop in polio epidemics.

For every case of known paralytic polio, there are about a thousand "subclinical polio infections," so mild they pass unnoticed, Dr. Ratner explained. These mild cases account for the high degree of natural immunity in adults. You can have a polio infection in the intestines without having paralytic polio or nonparalytic polio with enough symptoms to be diagnosed.

The theory of the Salk vaccine, made with killed polio virus, is that it will produce enough antibodies

the Polio Vaccines

Dr. Herald R. Cox has another oral vaccine.

Dr. Hilary. Koprowski . . . he wants fair play.

circulating in the blood to neutralize poliovirus before it can reach the central nervous system. But "one of the major disappointments of the killed vaccine" is that these circulating antibodies do not protect an individual against getting a polio infection in the intestines, nor its breakthru into the circulatory system, said Dr. Ratner. Protection against paralytic polio depends upon the presence of enough circulating antibodies to offset the virus, he explained.

Discussing the "very misleading way" in which the Salk vaccine data has been handled, was Bernard G. Greenberg, Ph. D., head of the department of biostatistics of the University of North Carolina, school of public health, and former chairman of the committee on evaluation and standards of the American Public Health association.

"There has been a rise during the last two years in the incidence rates of paralytic poliomyelitis in the United States," stressed Dr. Greenberg. "The rate in 1958 was about 50 per cent higher than that for 1957, and in 1959 about 80 per cent higher than that in 1958. If 1959 is compared with the low year of 1957, the increase is about 170 per cent.

"As a result of this trend in paralytic poliomyelitis, various officials in the public health service, official health agencies, and one large voluntary health organization have been utilizing the press, radio, and television and other media to sound an alarm bell in an heroic effort to persuade more Americans to take advantage of the vaccination procedures available to them," said Dr. Greenberg.

"Altho such a program might be desirable until live virus vaccines are available to us on more than an experimental basis, the misinformation and unjustified conclusions about the cause of this rise in incidence give concern to those interested in a sound program based on logic and fact rather than personal opinion and prejudice.

"One of the most obvious pieces of misinformation being delivered to the American public is that the 50 per cent rise in paralytic poliomyelitis in 1958 and the real accelerated increase in 1959 have been caused by persons failing to be vaccinated. This represents a certain amount of double talk and an unwillingness to face facts and to evaluate the true effectiveness of the Salk vaccine," said Dr. Greenberg.

The number of persons over 2 years of age in 1960 who have not been vaccinated cannot be more and must be considerably less than the number who had no vaccination in 1957, Dr. Greenberg pointed out. Then how can it be claimed that it is the large number of unvaccinated persons who are causing the increase in polio, when there were a larger number of unvaccinated individuals in 1957 when the vaccine was given credit for reducing rates of the disease.

"A scientific examination of the data and the manner in which the data was manipulated will reveal that the true effectiveness of the present Salk vaccine is unknown and greatly overrated," Dr. Greenberg stressed.

Why was there such a tremendous reduction in reported rates of paralytic polio in 1955, 1956, and 1957? Much of this highly publicized decrease was a statistical illusion, said Dr. Greenberg.

Prior to 1954, any physician who reported a case of paralytic poliomyelitis was doing his patient a favor because funds were available to help pay his medical expenses. At that time, most health departments used a definition of paralytic poliomyelitis which specified "partial or complete paralysis of one or more muscle groups, detected on two examinations at least 24 hours apart." Laboratory confirmation and the presence of residual paralysis were not required.

In 1955, these criteria were changed. Now, unless there is paralysis lasting at least 60 days after the onset of the disease, it is not diagnosed as paralytic polio.

During this period, too, "Coxsackie virus infections and aseptic meningitis have been distinguished from paralytic poliomyelitis," explained Dr. Greenberg. "Prior to 1954, large numbers of these cases undoubtedly were mislabeled as paralytic polio."

Thus, because the definition of the disease was changed and two similar diseases virtually ruled out, the number of cases of polio reported was sure to decrease in the 1955-57 period, vaccine or not. Then, too, physicians are reluctant today to diagnose paralytic poliomyelitis in a vaccinated child without thoro laboratory tests, thus eliminating most of the false positive cases commonly reported in the pre-1954 period.

"As a result of these changes in both diagnosis and diagnostic methods, the rates of paralytic poliomyelitis plummeted from the early 1950s to a low in 1957," said Dr. Greenberg. The recent increase in the disease, despite improved diagnostic methods, he believes, is due to a long term, increasing trend in the occurrence of polio.

"Without doubt, the increasing trend has been reduced to some extent by the Salk vaccine," explained Dr. Greenberg. "Nevertheless, the Salk vaccine has limited effectiveness in its ability further to reduce this trend. . . . Any future substantial reduction in this trend will require a more potent vaccine, not simply vaccinating more people.

"Today it may be a serious mistake to be ultra-conservative in accepting the various new live vaccines under the impression that there is no hurry because an almost equivalent immunizer exists in the Salk vaccine. A delay in accepting and promoting better vaccines will be a costly one. There must be immediate pressure applied to determine whether or not the new vaccines are more effective, so that we do not cling, for sentimental or personal reasons, to an older vaccine whose true effectiveness is today unknown."

The most accurate way we have of determining the effectiveness of vaccine (except by direct exposure to the disease) is to measure the levels of neutralizing antibodies in the blood, explained Herald R. Cox, Sc. D., director of virus research at Lederle Laboratories and president elect of the Society of American Bacteriologists. We do not know, he said, the exact level of antibodies necessary to protect against paralytic polio.

Herman Kleinman, M. D., an epidemiologist from the Minnesota department of health, pointed out that in antibody studies on children who have received three or more doses of Salk vaccine, he has found more than half do not have antibodies to two of the three types of polio strains used in the Salk vaccine. Twenty per cent lack antibodies to a third type.

"This is a very disturbing fact," said Dr. Kleinman. "If polio antibodies mean anything in respect to protection, then I am forced to conclude that much of the Salk vaccine we have been using is useless."

Dr. Kleinman also commented on the "changing concept of polio" and said physicians were reluctant to diagnose the disease without overwhelming evidence. He called the insistence on a 60 day duration

(Continued on Page 11)

Dr. Albert Sabin works on a culture for his live, oral vaccine. It has been used widely in Russia, but the United States public health service has ruled that it is not yet ready for licensing in this country.

POLIO

Is the Killer Still with Us?

(Continued from Page 9)

of paralysis in defining paralytic polio "silly."

Dr. Cox, who has worked in the virus field since 1929 and was the first person to prove that a killed vaccine could be made, commented on some of the problems of producing a potent, killed-virus vaccine.

"We are now learning, not only in the United States, but in Israel, England, and Denmark, that the killed product does a fairly good job of producing antibodies against Type II poliovirus," said Dr. Cox. "But Type II represents only about 3 per cent of paralytic cases thruout the world. The killed vaccine does a poor job against Type I, however, which causes 85 per cent of paralytic cases, and against Type III, which causes about 12 per cent.

"In other words, the killed vaccine is doing its best job against the least important type. It took time to find this out. It was proven in Israel in 1958, when it had its big Type I epidemic. They did not see any difference in protection between the vaccinated and the unvaccinated. Last year in Massachusetts during a Type III outbreak, there were more paralytic cases in the triple vaccinates than in the unvaccinated."

There have been problems, too, in the production of the killed Salk vaccine. An extra filtration step was added in November, 1955, Dr. Cox said, "because the amount of formalin used did not inactivate the poliovirus. We found residual live virus for as long as 42 consecutive days of inactivation."

Dr. Cox went on to assert that the second filtration step was "picked out of thin air with no experimentation to back it up," and that the extra filtration cut down on the effectiveness of the vaccine.

Mass vaccination with the Salk product started in April, 1955, and by April 26, there were reports of paralytic polio among vaccinated children, with deaths occurring in Idaho and California. Then came cases of polio among family members of vaccinated children. Live virus was discovered in the supposedly killed vaccine, altho it had been produced by the Salk procedure.

Dr. Ratner cited numerous instances in which live viruses were found in vaccine which was presumably safe, even in Dr. Salk's own standard vaccines. "It should be stressed that safety testing was inadequate when Dr. Salk developed the vaccine and when the vaccine was commercially prepared for the field trials of 1954 and for licensing and use in 1955," said Dr. Ratner. He added that in current vaccine, potency has been sacrificed for safety and that "at present, epidemiologic methods employed by the United States public health service to assure safety of the vaccine are inadequate."

Should the Salk vaccine continue to be used?

"There is no known way of preventing polio with a licensed product at the present time except thru the use of the Salk vaccine," answered Dr. Kleinman. "While I am an agnostic about the effectiveness of the Salk vaccine, I still believe it does something in preventing paralysis. So we owe it to the public to recommend its use. On the other hand, if we are going to act not only as public health physicians but as scientists we must continue our investigations into the truth about the Salk vaccine. On the basis of the facts as I know them, we must look for something better."

Other panel members agreed, pointing out that because all of the facts about the Salk vaccine have not been made public, physicians and public health officials find it difficult to resist the great pressures of public opinion built up thru an unprecedented publicity campaign urging the public to be vaccinated.

"Since nothing else is available, there seems to be no alternative but to push the use of it," commented Dr. Greenberg. "I don't think we should do so in ignorance, nor too complacently, believing that as long as we have something partially effective, there is no need to have something better. By being more cautious, we may make a mistake by accepting a better polio vaccine too slowly."

Dr. Salk (left) and Dr. Sabin clashed in 1955 hearings about the use of the Salk vaccine.

"When measured against its killed counterpart, a live virus vaccine (using modified virus which stimulate the production of anti-bodies but do not cause the disease) is always a superior vaccine," asserted Dr. Cox. He said it invariably costs much less. And it gives a higher degree of longer-lasting immunity. Dr. Cox has developed a live vaccine which was tested on thousands of school children and adults last year in Dade county, Fla., and also on thousands of persons in foreign countries.

Another live, oral polio vaccine has been developed by Dr. Hilary Koprowski, of Philadelphia's Wistar institute and has been tested on approximately 9 million individuals.

Dr. Koprowski has challenged the United States public health service decision last August to grant approval only to the Sabin vaccine. In a letter in the Jan. 14 Journal of the American Medical association, he said, "Altho it is a step forward that the principle of live virus immunization in poliomyelitis has at last been officially accepted, I am taking strong exception to this exclusive indorsement of one set of strains. In my opinion, such an indorsement should evoke a protest from individuals who believe that fair scientific judgment should be the basis for decisions affecting the physical welfare of man."

Amplifying his letter, Dr. Koprowski said, "It is my belief that government decisions, which are not based on proper evaluation of scientific data, are prompted by either poor choice of scientific advisers or by cryptic reasoning and that such ill-advised decisions could lead to development of an unhealthy climate in which scientists will see their contributions trampled upon by administrative agencies."

Discussing the development of live, oral vaccines, Dr. Cox explained, "Polio is unique because many more people get the infection than the disease." The problem in producing a live vaccine is to modify, or tame, the virus so that they will produce a mild infection strong enough to stimulate the formation of antibodies, but not the disease itself. A complicating factor in taming polio virus, is that three separate, tamed strains have to be developed to produce antibodies against the three chief types of polio.

A killed vaccine, such as the Salk, does not immunize an individual against an infection of polio virus in the intestines and, altho it can induce antibodies in the blood, this does not prevent the individual from becoming a carrier and spreading poliovirus, explained Dr. Cox.

Individuals receiving the live, modified, oral vaccines also eliminate poliovirus from their bodies for several days or several weeks after vaccination, but these are the tame, modified strains. Family contacts and even other individuals in the neighborhood can also acquire an immunity from these tame virus, altho they have never received the vaccine themselves.

However, some experts still fear that one of these strains may revert to its virulent type as it is passed from one individual to another, according to a report by Dr. Roderick Murray's committee, quoted in the Oct. 15, 1960, issue of "Modern Medicine." One solution, the committee suggested, might be to give the oral vaccine to entire communities in a brief time. This is a problem which must be solved before the Sabin vaccine is licensed.

Dr. Cox stated that using a live vaccine is the only way to eliminate wild, virulent polio strains in nature. Immunization with live vaccine probably would not protect a person for life, he added, but it would be cheap enough so you could afford it once a year.

Dr. Ratner compared Dr. Cox's vaccination figures with the 1954 field trials of the Salk vaccine. "The Cox live poliovirus has now been used by many investigators in over 2.5 million people, the other two live virus vaccines under study have been used in additional millions," he said. "Safety has been paramount in the minds of these investigators."

"On the other hand, Salk vaccine was used in only 400,000 persons in a single field trial which assumed safety and was primarily designed to determine effectiveness.

"An objective and fearless evaluation of the Salk vaccine is needed, for this is the necessary ingredient of an intelligent decision as to when the live virus vaccine should be licensed," Dr. Ratner continued. "Obviously, if the Salk vaccine is safe and highly effective, the United States public health service can take its time about licensing the live virus vaccine.

"If, on the other hand, polio and polio epidemics remain with us and children become paralyzed despite three, four, five, and six inoculations of Salk vaccine and vaccinees die, we cannot take our time."

What should parents do?

Take the advice of their podiatrician or family doctor and not be stampeded by TV commercials or overly-enthusiastic claims for vaccines. It is the individual physician who must decide which vaccine is safe and effective in what circumstances. But physicians must have honest, impartial, fully scientific information available to make this decision.

Currently, most physicians are still giving Salk vaccine shots. A few doctors do not. Some give them only if patients insist.

Once a live, oral vaccine is fully approved, it will be more effective than the killed Salk vaccine. Because of the doubt about the potency and effectiveness of the Salk vaccine in the past, a full course of the new vaccine will undoubtedly be recommended for everyone, regardless of how many Salk shots each individual has had.

Informed Consent Action Network

For Immediate Release: July 13, 2018

US District Court Judge signs order granting Plaintiff, Informed Consent Action Network (ICAN) and counsel, Robert F. Kennedy, Jr., the relief sought in a lawsuit against the US Department of Health and Human Services (HHS)

On Monday, June 9th, the United States District Court for the Southern District of New York signed an order granting Plaintiff, the nonprofit Informed Consent Action Network (ICAN), the relief it sought against the Defendant, the United States Department of Health and Human Services, HHS. ICAN was represented by Robert F. Kennedy, Jr.

In May 2017, ICAN Founder, Del Bigtree, Robert F. Kennedy, Jr.. and a handful of other individuals concerned about vaccine safety were selected by the White House to participate in a seminal meeting with the Counselor to the Secretary of HHS, the heads of the National Institute of Health, NIH, the Center for Disease Control, CDC, and Food and the Drug Administration, FDA. Del Bigtree and Robert F. Kennedy, Jr. suspected that HHS was not fulfilling its critical vaccine safety obligations as required by Congress in The National Childhood Vaccine Injury Act of 1986.

The 1986 Act granted unprecedented, economic immunity to pharmaceutical companies for injuries caused by their products and eviscerated economic incentive for them to manufacture safe vaccine products or improve the safety of existing vaccine products. Congress therefore charged the Secretary of HHS with the explicit responsibility to assure vaccine safety.

Hence, since 1986, HHS has had the primary and virtually sole responsibility to make and assure improvements in the licensing, manufacturing, adverse reaction reporting, research, safety and efficacy testing of vaccines in order to reduce the risk of adverse vaccine reactions. In order to assure HHS meets its vaccine safety obligations, Congress required as part of the 1986 Act that the Secretary of HHS submit a biennial reports to Congress detailing the improvements in vaccine safety made by HHS in the preceding two years.

ICAN therefore filed a Freedom of Information Act, FOIA, request on August 25th, 2017 to HHS seeking copies of the biennial reports that HHS was supposed to submit to Congress, starting in 1988, detailing the improvements it made every two years to vaccine safety. HHS stonewalled ICAN for eight months refusing to provide any substantive response to this request.

ICAN
Informed Consent Action Network

ICAN was therefore forced to file a lawsuit to force HHS to either provide copies of its biennial vaccine safety reports to Congress or admit it never filed these reports. The result of the lawsuit is that HHS had to finally and shockingly admit that it never, not even once, submitted a single biennial report to Congress detailing the improvements in vaccine safety. This speaks volumes to the seriousness by which vaccine safety is treated at HHS and heightens the concern that HHS doesn't have a clue as to the actual safety profile of the now 29 doses, and growing, of vaccines given by one year of age.

In contrast, HHS takes the other portions of the 1986 Act, which require promoting vaccine uptake, very seriously, spending billions annually and generating a steady stream of reports on how to improve vaccine uptake. Regrettably, HHS has chosen to focus on its obligation to increase vaccine uptake and defend against any claim vaccines cause harm in the National Injury Vaccine Compensation Program (aka, the Vaccine Court) to such a degree that it has abandoned its vaccine safety responsibilities. If HHS is not, as confirmed in Court this week, even fulfilling the simple task of filing a biennial report on vaccine safety improvements, there is little hope that HHS is actually tackling the much harder job of actually improving vaccine safety.

UNITED STATES DISTRICT COURT
SOUTHERN DISTRICT OF NEW YORK

INFORMED CONSENT ACTION NETWORK,

Plaintiff,

-against-

UNITED STATES DEPARTMENT OF HEALTH AND HUMAN SERVICES

Defendant.

STIPULATION

18-cv-03215 (JMF)

WHEREAS, 42 U.S.C. § 300aa-27, entitled "Mandate for safer childhood vaccines," provides as follows:

> (a) General rule
>
> In the administration of this part and other pertinent laws under the jurisdiction of the Secretary [of the Department of Health and Human Services], the Secretary shall—
>
> > (1) promote the development of childhood vaccines that result in fewer and less serious adverse reactions than those vaccines on the market on December 22, 1987, and promote the refinement of such vaccines, and
> >
> > (2) make or assure improvements in, and otherwise use the authorities of the Secretary with respect to, the licensing, manufacturing, processing, testing, labeling, warning, use instructions, distribution, storage, administration, field surveillance, adverse reaction reporting, and recall of reactogenic lots or batches, of vaccines, and research on vaccines, in order to reduce the risks of adverse reactions to vaccines.
>
> . . .
>
> (c) Report
>
> Within 2 years after December 22, 1987, and periodically thereafter, the Secretary shall prepare and transmit to the Committee on Energy and Commerce of the House of Representatives and the Committee on Labor and Human Resources of the Senate a report describing the

> actions taken pursuant to subsection (a) of this section during the preceding 2-year period.

WHEREAS, on August 25, 2017, Informed Consent Action Network ("ICAN") submitted a Freedom of Information Act request (the "FOIA Request") to the Department of Health and Human Services ("HHS" or the "Department"), which was assigned control number 2017-01119-FOIA-OS, that sought the following records:

> **Any and all reports transmitted to the Committee on Energy and Commerce of the House of Representatives and the Committee on Labor and Human Resources of the Senate by the Secretary of HHS pursuant to 42 U.S.C. §300aa-27(c).**

WHEREAS, on April 12, 2018, ICAN filed a Complaint for Declaratory and Injunctive Relief in the United States District Court, Southern District of New York against HHS seeking records, if any, responsive to the FOIA Request;

WHEREAS, the HHS Immediate Office of the Secretary ("IOS") maintains the official correspondence file of the Secretary of HHS, including reports to Congress by the Secretary of HHS, and therefore those files were most likely to contain records responsive to the FOIA Request;

WHEREAS, on June 27, 2018, HHS sent ICAN the following response to the FOIA Request:

> The [Department]'s searches for records did not locate any records responsive to your request. The Department of Health and Human Services (HHS) Immediate Office of the Secretary (IOS) conducted a thorough search of its document tracking systems. The Department also conducted a comprehensive review of all relevant indexes of HHS Secretarial Correspondence records maintained at Federal Records Centers that remain in the custody of HHS. These searches did not locate records responsive to your request, or indications that records responsive to your request and in the custody of HHS are located at Federal Records Centers.

WHEREAS, ICAN believes the foregoing response from HHS now resolves all claims asserted in this action;

IT IS HEREBY STIPULATED AND AGREED, by and between the parties by and through their respective counsel:

1. That the above-captioned action is voluntarily dismissed, with prejudice, pursuant to Federal Rule of Civil Procedure 41(a)(1)(A)(ii), each side to bear its own costs, attorney fees, and expenses; and

2. That this stipulation may be signed in counterparts, and that electronic (PDF) signatures may be deemed originals for all purposes.

Provider Incentive Programs: *An Opportunity for Medicaid to Improve Quality at the Point of Care*

Resource Paper

By:
Dianne Hasselman
Center for Health Care Strategies, Inc.

Made possible through support from The Commonwealth Fund.

March 2009

Contents

Introduction

Can there be such a thing as *too much* focus on quality? Imagine a primary care physician whose performance in diabetes care is assessed through incentive programs from multiple health plans. Each health plan uses slightly different performance indicators, requires different chronic care interventions, and provides different feedback reports for a subsection of the physician's patient panel — an overwhelming scenario, but unfortunately all too real.

Although the purpose of pay-for-performance (P4P) programs is to use financial incentives to "move the quality needle" in a deliberate manner and to increase value-based purchasing, the proliferation of incentive programs — particularly at the individual physician or practice level — is creating a patchwork of quality efforts with negative and unintended consequences. Many providers, frustrated with the numerous and fragmented performance reports they receive, discount or simply discard the data as confusing, inefficient, inaccurate, and unhelpful.

In recent years, there has been a groundswell among health policy experts, public and private purchasers, and payers toward greater standardization of quality improvement activities. Purchasers increasingly recognize the need for standardization around evidence-based guidelines. Significant movement has occurred in adopting nationally-recognized performance indicators to assess health outcomes. The National Quality Forum and its many partners are establishing national priorities and goals around performance measurement and reporting. National initiatives like *Aligning Forces for Quality*,[1] the *Regional Quality Improvement* initiative,[2] and *Bridges to Excellence*[3] are also helping to align public and private purchasers and payers around uniform quality improvement goals, common performance measures, and, in some instances, common payment.

By jointly developing incentive programs to improve quality at the point of care, purchasers and health plans can replace well-meaning but redundant and often conflicting pay-for-performance (P4P) programs. The resulting standardization of provider incentive programs could dramatically improve physician response to P4P efforts.

Medicaid and Provider Incentive Programs

With 63 million beneficiaries — 66 percent of whom are in managed care — and more than $361 billion in annual expenditures, state Medicaid programs are in an excellent position to impact quality at the point of care and to foster greater alignment across health plans and delivery systems.[4] Indeed, P4P programs are not new to states. Currently more than 25 states have P4P programs with their health plans or primary care case management (PCCM) programs.[5] Yet, while many states use P4P programs to motivate improvements at the health plan level, few have designed effective programs at the provider level.

Historically, states delegate responsibility for provider incentive programs to their managed care partners, particularly in risk-based managed care delivery systems. States have been reluctant to micromanage managed care operations and have encouraged plans to innovate. States have also been challenged to work within the regulatory parameters established by the Centers for Medicare and Medicaid Services (CMS) including a cap on total incentive payments in risk-based systems.

In addition to acknowledging the benefits of standardization, states are increasingly aware that quality ultimately must occur at the point of care. Many states understand that in the highly competitive managed care environment, collaboration and alignment across Medicaid plans — even around quality — occurs most readily when the regulatory and purchasing authority of the state is used. As such, there is growing involvement of state Medicaid agencies in provider incentive programs.

In 2006, with funding from The Commonwealth Fund and additional support from the Robert Wood Johnson Foundation, the Center for Health Care Strategies (CHCS) launched the *Pay-for-Performance Purchasing Institute* to help state Medicaid agencies design provider incentive programs. Seven states — Arizona, Connecticut, Idaho, Ohio, Massachusetts, Missouri, and West Virginia — worked with CHCS to develop and test physician-level financial and non-financial incentives, choose performance measures, engage providers effectively, and increase alignment across incentive programs. This resource paper presents examples, including several from that initiative, of how states are becoming increasingly involved in P4P at the practice level, particularly around efforts to improve alignment and standardization.[6]

Innovative State Models

The provider incentive program models described in this resource paper are based on the efforts of five state Medicaid programs:

- **Rhode Island** designed and implemented a provider incentive program that required Medicaid health plans to adopt standardized program goals, but allowed plans and providers to test different approaches to achieving those goals.

- **Arizona** is exploring the development of a provider incentive program that would require all Medicaid health plans to adopt common program goals, common performance measures, and to aggregate provider financial incentives across plans using a third-party broker.

- Since 2006, **Minnesota** has been participating in a provider incentive program where Medicaid and commercial purchasers and plans adopt uniform program goals and performance measures, and combine incentive dollars into "bucket" for provider payment.

- **Massachusetts** and **Missouri** are both focusing efforts around creating P4P program strategies and tools for use across different Medicaid delivery systems.

In considering the models above, a Medicaid program needs to recognize factors in its unique marketplace and circumstances, which may include:

- **Delivery system:** Will the incentive program operate in a risk-based managed care, primary care case management delivery system, or both?

- **Focus of P4P program:** Is the program targeting a chronic condition with a nationally-recognized measure set and a strong evidence base around impacting care (e.g., diabetes), or encouraging testing a new area with a less robust evidence base (e.g., reducing inappropriate emergency room utilization)?

- **Infrastructure:** Does the state have the infrastructure and staff to operate aspects of the program in house? The program design steps are consistent across models; however, "who does what" varies by state. In Rhode Island's model, the state is responsible for establishing and funding the provider incentive program, but the plans are responsible for the remaining steps. In Arizona's model, the state is more involved in all program design steps.

- **Political support:** Does the state have the political will and support to maximize alignment across plans? To join a multi-payer P4P program?

One size does not fit all in state-designed provider incentive programs, as illustrated by each of the following models, so states should consider their own unique circumstances when designing provider incentive programs.

Model 1: Alignment of Program Goals across Health Plans (Rhode Island)

Model 1 is based on Rhode Island's RIte Care P4P program. In 2005, the state required its health plans to implement a physician-level P4P component to compliment a health plan P4P program to reduce inappropriate emergency room (ER) use. The state had an incentive program at the plan level; however, with the prudent layperson laws and the Emergency Medicaid Treatment and Active Labor Act (EMTALA), the state and plans noted a gradual increase in ER utilization. The state decided to expand the incentive program to the point of care.

The state included a $0.95 per member per month (PMPM) increase to RIte Care's health plan capitation rate to be used for a primary care provider (PCP) incentive program. The state required that the additional PMPM payment be used to reward PCPs based on performance. Each plan was charged with designing a provider incentive program that promoted timely access to quality care, including preventive care, urgent care, and care during evening hours. Plans were not required to adopt the same provider-level measures or aggregate data into one rate per practice.

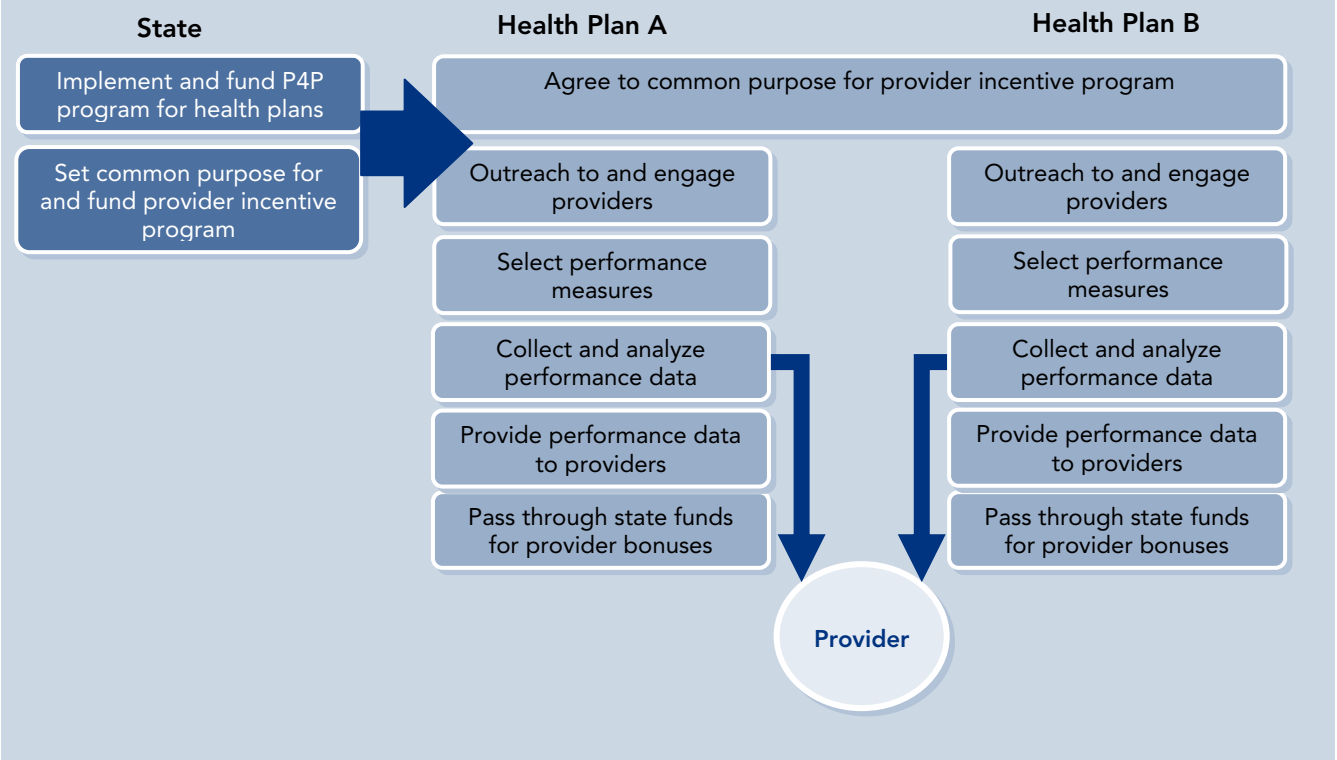
One of the plans, Neighborhood Health Plan of Rhode Island (NHPRI), targeted primary care practices with at least 200 NHPRI RIte Care members, creating a critical mass of potential new incentive dollars to "get the practice's attention." NHPRI divided the incentive payment into components. All eligible practices automatically received a payment of $0.30 PMPM during the first year. Practices that extended business hours or were open during the weekend received an additional PMPM amount. Practices that had multilingual practitioners on call after hours received an additional PMPM amount. Finally, practices that reduced ER utilization received an increase amount. Using this strategy, all eligible practices received some funding initially to work toward expanding access. Additional funding was not guaranteed or unlimited — progress had to be demonstrated over time. A subset of high-performing practices received the maximum amount for achieving specific outcomes.

Rhode Island's approach reflects its unique marketplace and delivery system. The state has a risk-based managed care program, so it operated the provider incentive program through its health plans. The program focus — reducing inappropriate ER utilization — did not have a strong evidence base of "what works." As such, the state wanted to leave ample room for the plans and providers to experiment. Adopting such an approach allowed the state and plans to test different provider incentive program designs and to compare and contrast what worked and what did not. The state is currently assessing outcomes data and convening its health plans to review, retool, and identify best practices.

States that are interested in testing provider incentive program options but are not yet ready to require greater alignment across plans or delivery systems might consider this strategy. Comparing and contrasting outcomes from different approaches would allow states to make more informed decisions in the future about how, where, and why to create greater standardization.

The figure below, based on Rhode Island's model, illustrates how a Medicaid program might design a provider incentive program across plans.

Model 1: Alignment of Purpose across Plans (Rhode Island)



Model 2: Alignment of Purpose, Measures, and Payment across Medicaid Plans Using a Third-Party Broker (Arizona)

Model 2 presents a provider incentive program that creates significant alignment across its Medicaid plans. It is based on a provider incentive approach that the Arizona Health Care Cost Containment System (AHCCCS) is exploring.

AHCCCS is considering a P4P program to improve care for 88,000 adult Medicaid beneficiaries with diabetes. In the proposed model, AHCCCS would aggregate claims data across Medicaid plans to calculate a provider's performance rate for all of his or her diabetic patients. In other words, the physician or practice would receive one consolidated diabetes performance report from the AHCCCS program, as opposed to a provider profile form each plan with whom the practice contracts. The proposed strategy aims to improve the validity and reliability of measurement and reduce the administrative burden on plans and providers alike.

Like the Rhode Island model, funds for provider bonuses would be included prospectively in the health plans' capitation rates. The health plans would be required to pass all state funds on to the providers. Incentive payments will be aggregated across plans into one payment per physician or practice. Thus a practice would receive one larger check, as opposed to multiple smaller checks. Because plans receive capitation rates prospectively, and provider performance would be measured and rewarded retrospectively, it

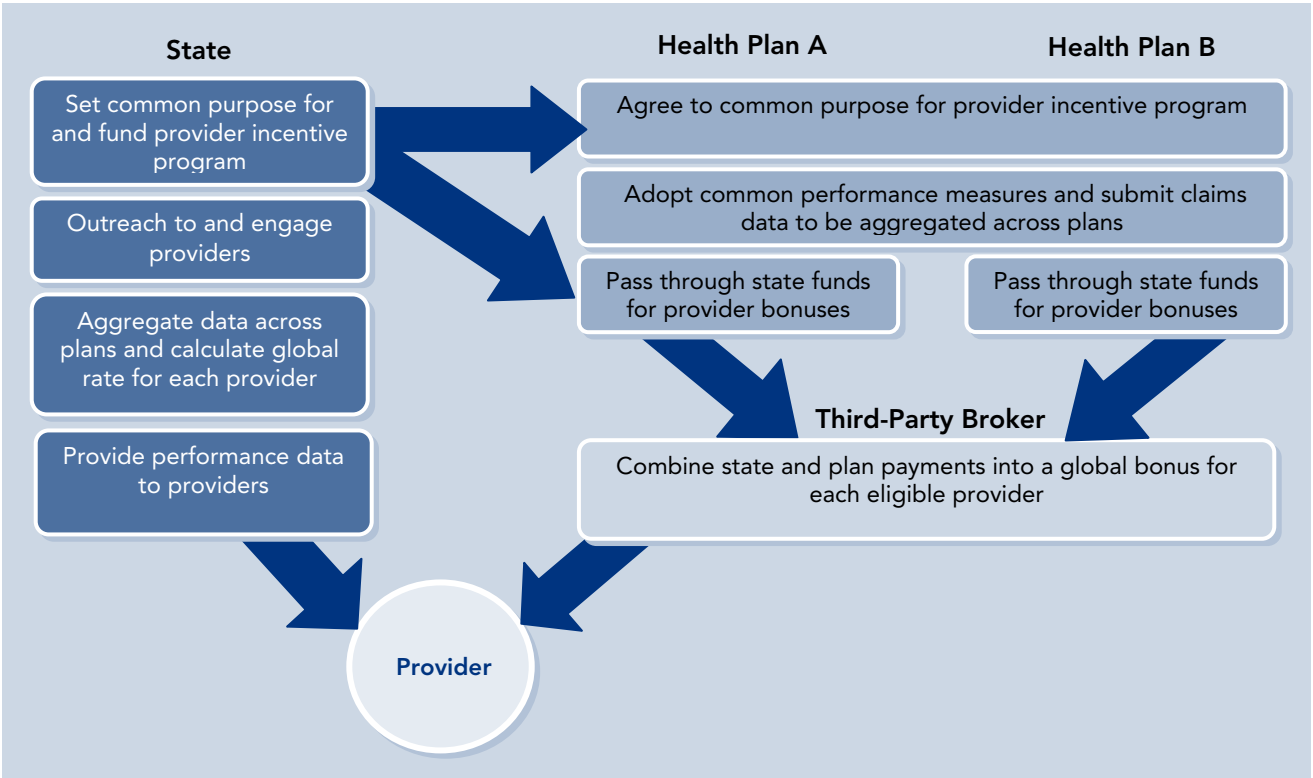
is possible that funds available for provider incentive payments might not be used in totality. Therefore, any remaining funds would accumulate and be used for provider incentive payments in the future.

The model that Arizona is exploring would use a third-party broker to receive and aggregate dollars from the plans, and to calculate and distribute bonus payments to practices. The state and CMS are currently exploring this broker model and whether and how it might be implemented.

Arizona's approach reflects its unique circumstances and delivery system. Like Rhode Island, Arizona operates a risk-based managed care delivery system, so any provider incentive program would need to operate through its plans. The potential program's focus — diabetes — has a nationally recognized set of measures and a strong evidence base around effective interventions. As such, the state could require plans to agree to a common set of measures. The state also has a rich source of high quality encounter data and a team of highly skilled data analysts who could calculate per practice or physician performance rates. Lastly, the large size of Arizona's program and the competitiveness of the managed care marketplace means that the state has significant purchasing leverage to direct quality improvement initiatives, if it so chooses.

The figure below, based on the model Arizona is exploring, illustrates how a Medicaid program might design a provider incentive program that is fully aligned across plans.

Model 2: Alignment of Purpose, Measures and Payment Across Plans Using a Third-Party Broker (Arizona)



Model 3: Alignment of Purpose, Measures, and Payment across Purchasers and Plans (Minnesota)

Model 3 is a cross-market collaboration that adopts a provider incentive program that is uniform across public *and* private purchasers (e.g., employers, Medicaid agencies, state employees, etc.) and plans (e.g., commercial and publicly funded). It is based on Minnesota's existing cross-payer provider incentive program. In this model, purchasers and plans use the same measures to assess provider performance and combine financial resources to reward high-performing physicians.

Such an approach has many benefits:

- Purchasers increase their buying power by banding together, focusing on value-based care, and demanding more efficient and effective health care.
- Plans must deliver value as purchasers make contracting decisions based on performance data. Plans benefit from creating economies of scale and reducing fragmentation of quality improvement activities.
- Practices are assessed by a common set of measures and a single report, which reduces administrative burden and confusion.
- When performance data is shared publicly, consumers have the opportunity to become more informed and active participants in their health care.

While public-private payer P4P programs are still in their infancy, the alignment and standardization created by this model holds great promise for Medicaid and commercial purchasers, providers, and consumers.

Minnesota's marketplace has unique characteristics that have helped accelerate innovations in quality. Its health care system is highly integrated. Hospitals and health systems own most primary care groups. As such, there is not only a strong business case to create alignment throughout a health care system, but the ability to do so.

Health care providers in Minnesota are required to serve the Medicaid population. This integration reinforces the importance of including Medicaid in cross-payer initiatives.

Lastly, Minnesota has created an infrastructure to support quality and innovation throughout its health care system. Three key building blocks have been particularly integral to Minnesota's achievements in value-based purchasing:

- **The Buyers Health Care Action Group** (BHCAG) is a coalition of private and public purchasers that seeks to promote purchasing strategies and develop tools that help purchasers buy and evaluate health care based on performance and value, not just price. BHCAG initiated Minnesota's diabetes provider incentive program in 2004.[7]
- **The Institute for Clinical Systems Improvement** (ICSI) develops evidence-based guidelines and measures for physician performance evaluation, and provides implementation support.[8]

[7] For more information about Minnesota's Buyers Health Care Action Group, visit **www.bhcag.com**.
[8] For more information about the Institute for Clinical Systems Improvement, visit **www.icsi.org**.

- **Minnesota Community Measurement** (MNCM) is a collaborative that receives and aggregates claims data from plans, collects clinical data from practices, and reports provider-level performance rates for conditions such as diabetes and cardiac disease. [9]

It is within this unique environment that BHCAG implemented a Bridges to Excellence (BTE) program to achieve optimal diabetes care in 2005. BTE is a national employer-led P4P program with a standard data exchange platform and performance measurements to foster cross-market collaborations in regions or states. Using evidence-based guidelines and measures developed by ICSI, MNCM collects, aggregates, and reports performance data for practices and clinics. BHCAG receives and aggregates financial incentives from purchasers, including Medicaid, and pays providers based on their performance.

In 2007, Minnesota's Department of Human Services (DHS), the state's Medicaid agency, joined BHCAG's effort and began to enroll Medicaid managed care recipients ages 18 to 75 with diabetes or cardiac disease into the initiative. DHS rewards practices based on their share of Medicaid patients, as opposed to clinical results. DHS includes dollars for provider incentives in health plan capitation rates. The plans, in turn, give those dollars to BHCAG.

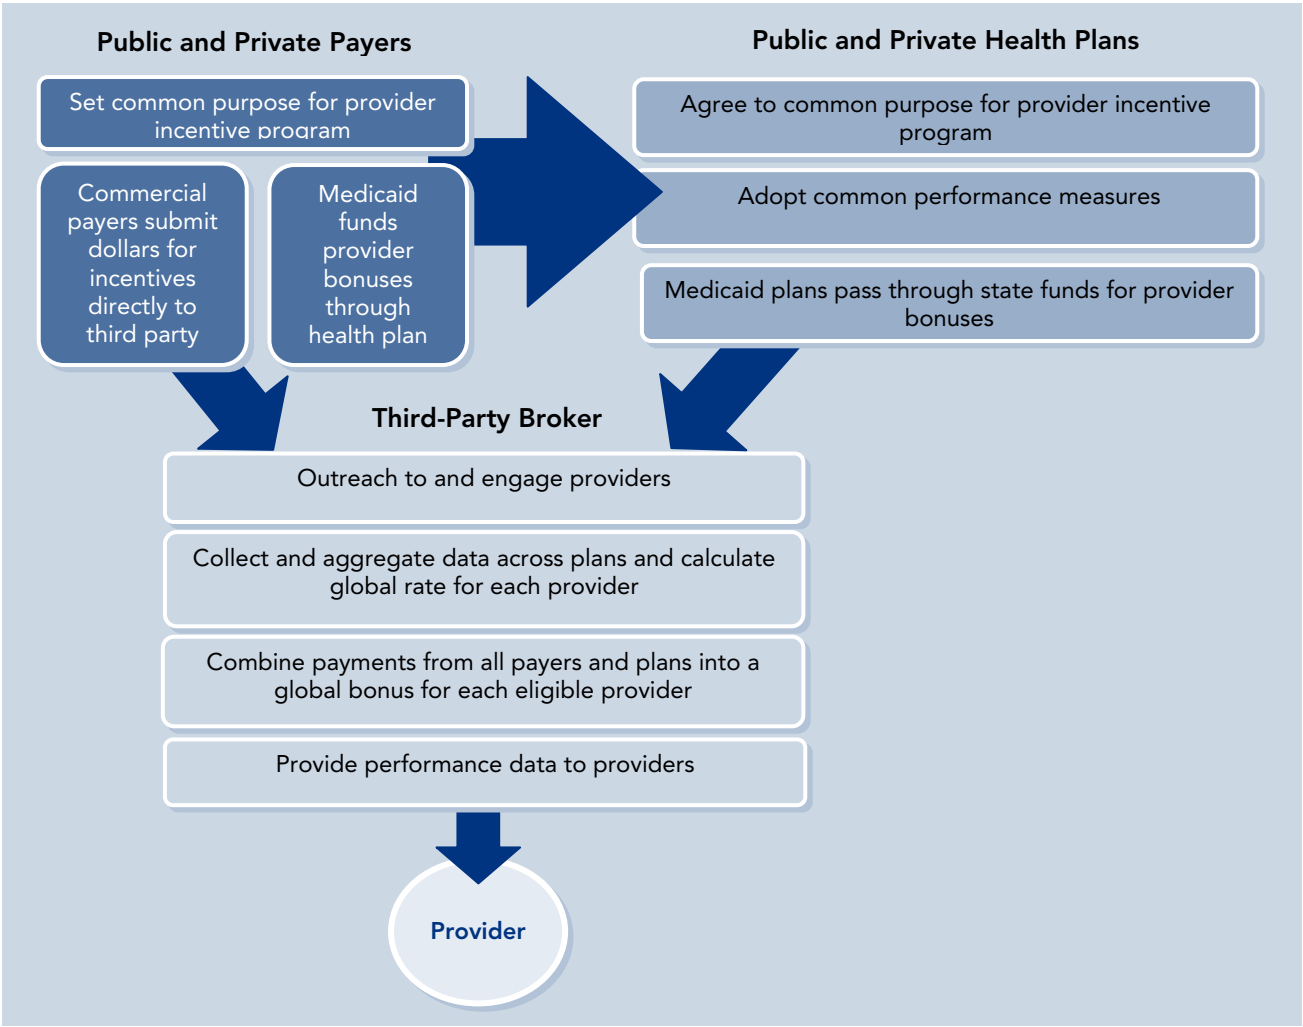
Through the BTE program, physicians providing optimal diabetes care to at least 10 percent of their patients with diabetes receive $100 per patient. In 2006, BHCAG paid physicians $97,000 in rewards, and rewarded $260,000 in 2007.[10] The percentage of Minnesotans receiving optimal diabetes care from providers participating in the BTE program has increased from 6 percent in 2004 to 22 percent in 2007.

DHS recently received approval from CMS for a new provider incentive program. This program will focus on Medicaid recipients remaining in fee-for-service. This population comprises 30% of Medicaid recipients, many of whom are disabled. Diabetes prevalence in this population is 10%, compared to 6% in the Medicaid managed care population. DHS will directly reward individual practices providing optimal care to Medicaid fee-for-service recipients with diabetes or cardiac disease. DHS will pay $125 per diabetic for the first year, and up to $500 for optimal performance in subsequent years. Practices will submit their data to DHS electronically.

The figure below, based on the model that Minnesota implemented, illustrates how to create full alignment across payers and plans.

[9] For more information about Minnesota Community Measurement, visit **www.mnhealthcare.org**.
[10] BHCAG March 2008 presentation at the CHCS Medicaid Purchasing Leadership Summit.

Model 3. Alignment of Purpose, Measures and Payment across Payers and Plans (Minnesota)



While several state Medicaid agencies have expressed interest in provider incentive programs that are aligned across purchasers and plans, Medicaid's engagement to date has been limited. States may face multiple challenges participating in a multi-payer P4P program. States have concerns about how data will be collected and used publicly. Public-private programs work best when there is a significant overlap of providers who serve both the commercial sector and Medicaid patients. States with comparatively low Medicaid reimbursement rates often have provider networks with a less integrated patient mix. Lastly, some Medicaid programs may struggle to obtain the funding necessary to adequately support and sustain provider incentive programs.

Model 4: Alignment of Purpose, Measures, and Interventions across Delivery Systems (Massachusetts and Missouri)

Model 4 depicts provider incentive programs being designed in Massachusetts and being implemented in Missouri. Both states developed P4P approaches within a non-risk-based context (PCCM or fee-for-service), with the intent to extend select program elements to the risk-based managed care delivery system in the future.

MassHealth, the Commonwealth's Medicaid program, is designing a provider incentive program for its Primary Care Clinician (PCC) Plan based on the following principles:

- Transparency and collaboration;
- Alignment with the existing data collection and reporting system;
- Minimization of provider reporting burden; and
- Consistency with established state and national P4P programs.

The program will measure performance of individual physician practices, group practices, community health centers, hospital-licensed health centers, and hospital outpatient departments. To participate in the clinical measures portion of the incentive program, providers must have a minimum number of Medicaid patients in the denominator of each clinical measure in the P4P program and must complete a practice survey.

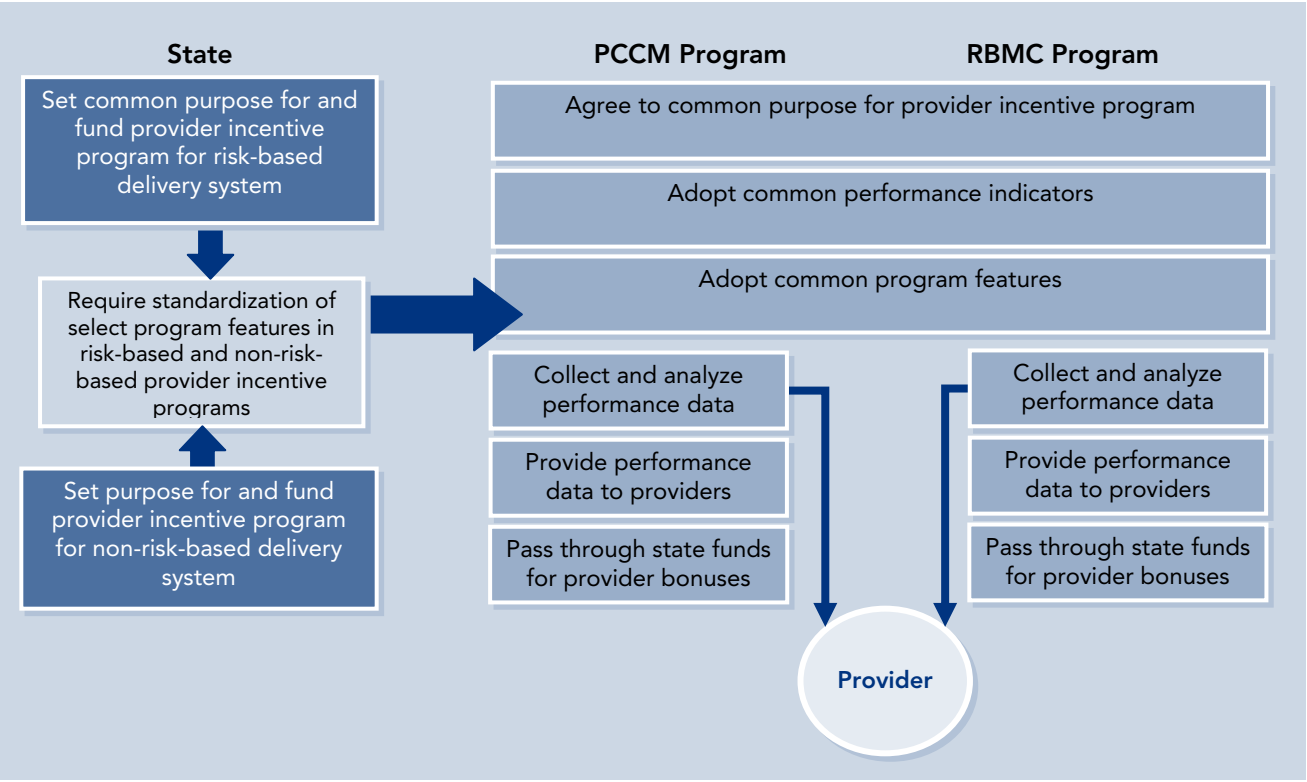
The practice infrastructure survey will be used to assess critical medical home components including: HIT capacity, follow-up from tests, referrals and acute events, guideline-based reminder systems, registries, access, and the process for gathering and tracking race and ethnicity information. During the first year of the program, practices will receive a "pay for reporting" amount if they fully complete and return the practice survey. Practices completing the survey will be assessed for eligibility for P4P funds based on their clinical indicator performance.

Provider performance around prevention and diabetes care will be assessed using HEDIS-based measures that are already collected and reported through the PCC Plan's profiling activities. MassHealth's new P4P program will allow providers to review their individual rates and submit additional information if they believe the rates are inaccurate. Payments will be based on achieving the performance benchmark for the clinical measures, or achieving improvement for clinical measures even though they do not meet the established benchmark rate. Incentives will be paid on a PMPM basis, based on the provider's total PCC Plan member enrollment. The state is still developing the specific PMPM amount.

The state is creating alignment across MassHealth's P4P programs. Specifically, all individual health plan provider incentive programs, including the new PCC Plan, will be required to use the same measures. They will also be required to use the same practice infrastructure survey tool.

The state of Missouri is also creating alignment with its fee-for-service (FFS) and risk-based managed care delivery system through a provider incentive program. Currently, physicians or mid-level practitioners in high-volume federally qualified health centers (FQHCs) in targeted geographic areas receive incentives for developing electronic care plans for patients with diabetes, asthma, gastroesophageal reflux disease, cardiovascular disease, or chronic obstructive pulmonary disease. The state pays providers $25 for developing the initial patient assessment online, and an additional $10 for updating web-based care plans. To assist providers with developing care plans, the state is placing care coordinators in the high-volume FQHCs to act as a liaison between the PCP and the patient. Missouri is currently revising its health plan contract to include the same provider incentive program.

Model 4. Alignment of Purpose, Measures, and Interventions Across Delivery Systems (Massachusetts and Missouri)



State Provider Incentive Program Profiles

Following are brief descriptions of additional state provider incentive programs:

Connecticut
Connecticut is working closely with its health plans to design and phase in a provider incentive program aimed at improving EPSDT rates. The first phase is to reward PCPs for completeness of EPSDT encounters. To do this, the state added payment incentives directly to the EPSDT reimbursement process so that medical practices can devote the time and resources necessary for care coordination. The state is now focusing on options for measuring and rewarding care coordination at the practice level. Specifically, the state will provide bonus payments through the health plan capitation rate to PCPs who coordinate care with specialists as appropriate based on EPSDT screening results.

Idaho
Idaho is piloting a provider incentive program within its PCCM delivery system and disease management program. Although the program will ultimately target five chronic diseases (diabetes, asthma, depression, hyperlipidemia and hypertension), the state made a strategic decision to "start small" by focusing first on diabetes. The state is targeting the pilot program to three high-volume FQHCs equipped with electronic medical records to facilitate data capture.

The diabetes program aligns with the state's existing disease management program and targets approximately 500 diabetics within the state. While Idaho is using nationally-recognized performance measures to assess changes in outcomes, it is initially rewarding practices based on process measures. Specifically, practices receive $50 per patient enrolled in the state's diabetes disease management program. They also receive $10 for each of the six diabetes measures reported. To date, the state has paid $20,000 to the three FQHCs. The state has $500,000 available for incentive payments as it continues to expand the P4P program. Next steps include establishing a secure web-based data submission and collection system.

Ohio
Ohio began exploring options for provider incentive programs by soliciting feedback from its health plans, provider community and other key stakeholders. A series of focus groups revealed physician frustration regarding the variety of measurement sets across different payers and plans. One medical director of a large primary care network described nine different measurement sets for which his organization is accountable. Physicians also voiced concerns with the accuracy of administrative data and were more likely to support P4P if their own data was used for measurement.

The state also surveyed health plans regarding the range of P4P methodologies, potential performance indicators, and estimated distribution of physician rewards over the various performance measurement domains. One key finding was that physician-level measurement, reporting and incentives could be complicated by the small numbers of encounters and measurable events at the physician-level. The state identified that only 12 percent of practices had a volume of 30 or more Medicaid patients — the number they estimate to sufficiently evaluate performance.

One option being considered is joining Cincinnati's Bridges to Excellence Diabetes Care Link program. Cincinnati, one of the original BTE pilot markets, has been active since 2003. Physicians in the program who demonstrate they are top performers in diabetes care can earn up to $100 for each patient covered by a participating employer. Employers (currently private only) fund incentives from documented savings achieved through lower health care costs and increased employee productivity that results from improved diabetes care.

Due to budgetary constraints, Ohio Medicaid has "tabled" short-term plans around developing a provider incentive program, but continues to consider its opportunities moving forward.

West Virginia
West Virginia is considering a provider incentive program that would support the state's Mountain Health Choices program. Mountain Health Choices offers a two-tiered benefit system — beneficiaries must sign a "personal responsibility" agreement to receive enhanced benefits. Through the agreement, the beneficiary acknowledges the role he/she plays in his/her health care delivery. The state is considering implementing a provider incentive program that rewards physicians and mid-level practitioners as they encourage and work with Medicaid recipients in completing the agreements. Due to budgetary constraints and limited resources, the state plans to revisit its P4P programs — both at the plan and provider level — in the near future.

Conclusion

While the number of provider-level incentive programs is low compared to plan-level programs, provider P4P initiatives are increasing with the greater awareness that health care is local and quality ultimately occurs at the point of care when the patient meets face-to-face with the provider.

The provider P4P models highlighted herein can help states identify options for creating greater standardization in their quality improvement activities, particularly in a risk-based managed care delivery system. Alignment of P4P programs can improve the validity and reliability of performance measurement, reduce administrative burdens on plans and providers, and create economies of scale for plans and breakthroughs in quality for patients — all of which lead to reductions in future cost growth. This resource paper deliberately highlights states that have chosen different levels of alignment, recognizing that states will vary in terms of their interest in and ability to create standardization.

This resource paper reflects the growing recognition of the need to standardize quality improvement initiatives to send a stronger message to providers. Fragmentation in quality improvement efforts creates duplication and confusion for providers. Provider incentive programs offer purchasers an opportunity to become more involved in improving quality at the point of care and in achieving a greater level of standardization across P4P programs. Although P4P is just one tool in the quality improvement "arsenal," Medicaid programs can play an important role in creating much needed alignment in P4P.

Appendix

Background on P4P

Pay-for-performance (P4P) programs are voluminous and growing throughout the public and private sectors as payers increasingly look for ways to link payment and quality. While many events have contributed to the proliferation of P4P programs, a few seminal events and initiatives are highlighted in this section.

The earliest P4P efforts were initiated by plans seeking to measure provider performance around cost and utilization, more so than quality. As employers saw their health care costs rising, they sought to link payment with health outcomes through health plans, which were responsible for a growing proportion of their employees. Plans were a logical starting place because they already collect standardized performance measures through the Healthcare Effectiveness and Data Information Set (HEDIS®) measures and customer satisfaction information through the Consumer Assessment of Healthcare Providers and Systems (CAHPS®) tool. Plans also have the capacity to collect and report data and are responsible for performance in many settings.

In 2001, the Institute of Medicine (IOM) released its groundbreaking report, *Crossing the Quality Chasm*, which revealed that up to 98,000 Americans die each year as a result of medical errors.[11] The IOM report stated that payers need to align payment policies to support quality improvement, as they often were paying more for poorer outcomes. This report was followed by one from RAND in 2003 that documented that patients receive the recommended care approximately half the time.[12] Both of these reports resonated deeply with health care purchasers, payers, providers, and consumers, and reinforced the need to link payment with performance.

As P4P grew in the private sector, public payers also began to link payment to performance. Medicare, for example, launched several P4P demonstration programs, targeting hospitals and physician practices. State Medicaid programs also began implementing P4P programs — some as early as the 1990s. Initial efforts focused on accountability, rather than quality or value, and targeted health plans. Because states began managed care enrollment with the Temporary Assistance for Needy Families (TANF) population, early P4P programs tended to focus on measures specific to services that mothers and children typically received, such as prenatal care visits, well-child checkups, and immunizations. Over time, as states have enrolled high-cost, high-need Medicaid beneficiaries into care management programs, P4P programs have expanded to focus on outcomes related to complex conditions and special needs.

As states have become more sophisticated purchasers of care and more proficient at collecting and using performance data and measures, P4P programs have become more advanced and targeted. As of July 2006, 28 state Medicaid agencies operated P4P programs, and half of those programs were operating for five or more years. Again, the majority of these programs were at the health plan level, followed by those targeting primary care case management (PCCM) programs, nursing homes, hospitals, behavioral health care providers, and lastly, individual physicians. In 2006, 19 states were planning to expand existing P4P programs in the next five years, and 15 Medicaid agencies were planning to start their first P4P programs.[13]

The growing availability of performance data, the increasing demand for value-based purchasing, and a greater national focus on creating more alignment and standardization around quality have contributed to the proliferation of P4P initiatives, particularly to measure performance at the point of care. A few of the most notable ones are described below.

Rewarding Results: Aligning Incentives with High-Quality Health Care

Rewarding Results was a three-year effort funded by the Robert Wood Johnson Foundation, the California HealthCare Foundation, and The Commonwealth Fund. The three foundations selected seven demonstration projects that made providers eligible for financial and non-financial rewards based on the achievement of specific quality goals linked to clinical quality. The demonstration projects offered varied approaches, typically targeting primary care physicians or physician organizations, and represented several types of insurance arrangements, (e.g., health maintenance organizations (HMOs), preferred provider organizations (PPOs), and Medicaid.)

Through use of incentives, the *Rewarding Results* projects significantly increased patient visits to the doctor; pushed physicians to embrace health information technology (HIT) and electronic medical records (EMRs) at a faster pace; increased the number of patients receiving annual mammograms and other screenings; and motivated physicians to monitor patient care more aggressively, particularly for chronically ill patients. The initiative included seven experimental projects — three of which are described below — designed to test a variety of P4P models.

Integrated Healthcare Association (IHA)
Created in 1996, the Integrated Healthcare Association is a California-based, statewide coalition of health plans, physicians, health care systems, purchasers, and consumers working to create the business case for quality at the physician group level. In 2003, IHA initiated its P4P program with the goal of rewarding physician groups for performance in clinical care, patient experience, and HIT investment based on common metrics and public reporting. Key to the program's success has been the use of uniform measures to evaluate performance across multiple health plans, physician groups, and patient populations. To date, it is the largest P4P initiative in the country.

Bridges to Excellence
Bridges to Excellence (BTE) is the largest employer-sponsored effort rewarding and recognizing physicians for meeting specific quality benchmarks. For the *Rewarding Results* initiative, the BTE employer coalition focused on four locations across the country and financially rewarded physicians per patient per year for excellence in diabetes and/or cardiac care. The BTE model is now in several markets across the country and has found that physicians who are recognized for providing high-quality and more efficient care deliver it at 15 to 20 percent lower cost than physicians not participating in the program.

Local Initiative Rewarding Results
Local Initiative Rewarding Results was the largest collaborative P4P effort to improve the health of babies and teens in Medicaid. The California-based project involved seven health plans that collaborated to test the impact of financial and non-financial incentives on provider quality. The program, which ran from 2002 through 2004, ultimately paid $5 million in provider incentives and involved 3,300 physicians touching the lives of 350,000 babies, adolescents, and parents. Five of the seven plans improved the rate of well-baby visits, with increases from 4 to 35 percent. Visits to the doctor by teens increased from 7 to 14 percent at six of the seven plans. Of the seven *Rewarding Results* projects nationwide, the *Local Initiative Rewarding Results* project was the only activity focusing on the Medicaid population and the first known collaborative effort to establish financial incentives within Medicaid among multiple plans with the same objective.

The Leapfrog Group

The Leapfrog Group was established in 2002 to mobilize employers' purchaser power in relation to health care services and to influence the quality and affordability of care. The *Crossing the Quality Chasm* report focused Leapfrog initially on reducing preventable medical mistakes, recommending that large employers provide more market reinforcement for the quality and safety of health care. The Leapfrog Group launched its Hospital Rewards Program in 2005 and continues to measure hospital cost and quality performance. Hospitals that demonstrate excellence or show improvement along both dimensions receive rewards.

Medicare P4P Demonstration Programs

The Centers for Medicare and Medicaid Services (CMS) has been instrumental in establishing demonstration projects for P4P at the point of care. Two of its key P4P demonstration projects focused on physician practices are described below.

Physician Group Practice (PGP) Demonstration
In 2005, CMS launched its two-year Physician Group Practice (PGP) Demonstration focusing on improving the quality of care delivered to patients with congestive heart failure, coronary artery disease, and diabetes mellitus. Ten large, multi-specialty group practices participated in the demonstration project and received $16.7 million in incentive payments for improving health outcomes and coordinating the overall health care needs of Medicare patients assigned to their groups.

Physician Quality Reporting Initiative (PQRI)
A related CMS value-based purchasing initiative is the Physician Quality Reporting Initiative (PQRI), which uses a pay-for-reporting approach. Under PQRI, physicians and other health care professionals earn incentive payments for reporting measurement data about the quality of care they provide to Medicare patients. CMS is now developing a program that moves from the PQRI pay-for-reporting approach to a performance-based payment plan.

CMS Payment Polices and Federal Regulations

The Centers for Medicare and Medicaid Services provides policy guidance on provider incentive programs that states must consider as they develop P4P programs in risk-based managed care and PCCM programs.

Payments to Providers
Under risk-based managed care, because a contractual relationship exists between the state and its plans, states are prohibited from paying providers outside of the health plan contract. In other words, states are restricted from making direct incentives payments to providers. As an alternative, a state can include funds for a provider incentive program in the health plan's capitation rate, then contractually require the health plan to pass the full incentive payment on to eligible providers.

In a PCCM environment, a state can make incentive payments directly to eligible providers or have the PCCM administrator pass through the bonuses to eligible providers. The state must specify the incentives in its State Plan, and the incentives must be tied to payments for services, as specified in the State Plan.

Incentive Payment Amounts
Incentive payments from the state cannot exceed 105 percent of the payments attributable to services covered by the incentive arrangement.[14] In risk-based managed care, total payments (capitation payments

[14] 42 CFR 438.

plus any incentive amounts) cannot exceed 105 percent of the approved capitation rate attributable to services covered by the incentive arrangement. A state could not, for example, offer a 3 percent incentive payment to its health plans, and an additional 3 percent as a "pass through" to physicians.

In a PCCM delivery system, the 105 percent ceiling is based on services that impact the P4P program target, and may include inpatient hospital, emergency room services, and other services as well as those provided or authorized by the physician, practice, or other PCCM provider. A state should work with CMS to develop an incentive methodology that fits its PCCM program design. Research shows that incentive payments must be large enough to be meaningful in order to motivate a change in behavior. As such, limits on incentive payments may present an even greater reason to collaborate with other purchasers, particularly when Medicaid can benefit from pre-existing quality improvement programs.

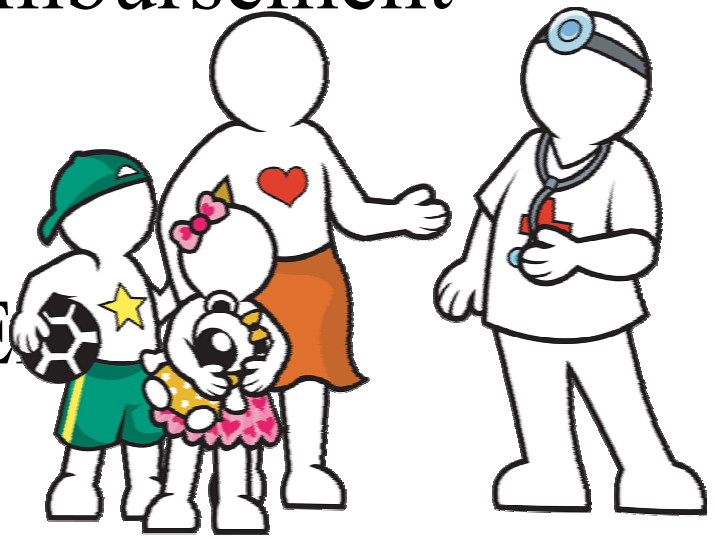
The IEHP Pay For Performance Program

IEHP Pay for Performance Program (P4P)

- ⇨**Goals**
- ⇨**Methodology**
- ⇨**Evolution**
- ⇨**Outcomes**

Goals

- Motivate Physicians to Provide Services
  - Outreach to assigned Members
  - 'Capture' when Member in office
  - Report the event
- Increase Physician Reimbursement
  - Beyond Capitation payments
  - Pediatricians
  - OB/Gyns
- 'Bind' Physicians to IE
  - Direct Payments from IEHP
  - Significant Percent of Income



Methodology

- Direct to Physician Payments
- Fee For Service Model
- ‘Easy’ Billing
- Timely Submission
- Timely Payments

➢ NOT CHDP or CPSP

The Beginning

The Evolution of P4P at IEHP

- The IEHP Immunization Program was the first attempt at a physician incentive program
- Launched September 1997
- Goal was to increase the immunization rate of IEHP Members 0-2 years of age.

The Beginning cont….

- Program provided direct reimbursement to physicians for immunizations
- Immunizations were submitted to IEHP via the PM160 form - only change was adding series #

PIP: The Physician Incentive Program

- In April 2000, the Physician Incentive Program was launched
- The new PIP program consisted of 5 components
  1. Immunizations
  2. Well Child Visits
  3. IHA/Adult Physical
  4. Perinatal Services
  5. Health Education Behavioral Assessment (HEBA)

PIP: The Physician Incentive Program cont…

- Well Child Visit Component
  - Physicians were reimbursed $50 for each well child visit done in accordance with the IEHP Well Child Visit schedule for Members 0 to 18 years old
  - Exams done during the first 120 days of enrollment were paid an additional $50 bonus

PIP: The Physician Incentive Program cont…

- Perinatal Services Component
  - Designed to ensure that all IEHP Members receive timely prenatal and postpartum care
  - Reimbursement Schedule

    $200 if date of service for initial visit in the 1st trime

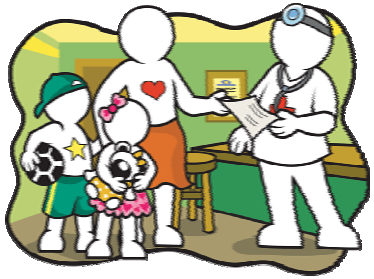
    $100 if the 2nd trimester

    $50 if in the 3rd trimester

    $50 for a postpartum exam within 8 weeks of delive

PIP: The Physician Incentive Program cont…

- In January 2001 the PIP program was redesigned
  - The IHA and HEBA components were removed
  - Reimbursement for Pap Tests was added - $25 reimbursement on CMS 1500
- In August 2001, Chlamydia Screening was added to the P4P program - $25 on CMS 1500



PIP: The Physician Incentive Program cont…

- In January 2003, the Diabetes component was added to PIP
- Providers were reimbursed $25 for each of the following:
  - HbA1c Tests
  - LDL Screening
  - Retinal Exams
  - Foot Exams

Pay For Performance

- With an increasing importance being placed on HEDIS results by DHS, MRMIB, and NCQA, IEHP decided to overhaul the PIP program
- In July 2004, the new Pay For Performance Program (P4P) was launched
- The P4P program is HEDIS-centered

Pay For Performance cont…

- Implemented a $100 bonus for
  - Completion of 6 well child visits by 15 months
  - Submission of a complete immunization record prior to age 2
- Significantly increased perinatal payments
- Implemented outcomes bonuses for Diabetes:
  - $50 For HgbA1c of 7.0 or less
  - $50 For LDL of 100 or less
- Added Asthma Component (9/1/05)
  - $25 for asthma progress note on-line
  - $20 for paper

Pay For Performance

Questions

The Payoff

- The Program is designed to increase the provision of preventive health services to our Members as well as to improve HEDIS results and we have achieved success in both areas
- Our P4P program has made a tremendous impact on our HEDIS results

Pay for Performance (P4P) Program Guide

Contact: QualityPrograms@iehp.org
Published: March 28, 2018

PROGRAM OVERVIEW

This program guide provides an overview of the 2018 Global Quality Pay for Performance (GQ P4P) Program for Independent Physician Associations (IPAs). In this third year of the program, IEHP has made program enhancements based on feedback from Providers in an effort to continually improve effectiveness. The IEHP GQ P4P program for IPAs is designed to reward IPAs for high performance and year-over-year improvement in key quality performance measures. This program overview is designed for IPAs and their staff as an easy guide to help maximize GQ P4P.

This year's GQ P4P Program continues to provide financial rewards to IPAs for improving healthcare quality across multiple domains and measures. The 2018 GQ P4P program focuses on performance-based incentives to IPAs for services rendered in 2018.

If you would like to get more information about IEHP's GQ P4P Program or best practices to help improve quality scores and outcomes, visit our Secure Provider Portal at ***www.iehp.org***, email the Quality Team at ***QualityPrograms@iehp.org*** or call the IEHP Provider Relations Team at 909-890-2054.

What's New?

Two measures were retired

- Annual Monitoring for Patients on Persistent Medications - Total
- Childhood Immunizations - Combo 3

Three measures were added to the Clinical Quality Domain

- Avoidance of Antibiotic Treatment in Adults with Acute Bronchitis
- Weight Assessment and Counseling for Nutrition and Physical Activity for Children and Adolescents
- Concurrent Use of Opioids and Benzodiazepines (monitoring only)

New Tier 1 and Tier 2 goal methodology includes a 'practical significance' standard

The budget was reduced from $30 million to $20 million, with removal of the condition to pass through 33-50 percent of the funding to Primary Care Providers (PCPs), which was in place for previous program years.

Eligibility and Participation

To be eligible for incentive payments in the 2018 GQ P4P Program, IPAs must meet the following criteria:

- Have at least 5,000 IEHP Medi-Cal Members assigned as of January 2018
- Have at least 30 Members in the denominator as of December 2018 for each quality measure to qualify
- Submit a GQ P4P Quality Work Plan to IEHP by March 1, 2018 in order to enroll in the program (see Work Plan details in Appendix 5)
- Meet minimum Encounter Data Gates in order to qualify for incentive payments

Minimum Data Requirements

Encounter Data

Encounter data is foundational to performance scoring and is essential to success in the GQ P4P Program. Complete, timely and accurate encounter data should be submitted through normal reporting channels for all services rendered to IEHP Members. Please use the codes listed in Appendix 2 to help with proper coding to meet measure requirements.

Lab Results

Data from lab results is also foundational to Program performance scoring. Providers should ensure they submit complete lab results data for services rendered to IEHP Members. IPAs should work with their network Providers to ensure they are using the appropriate lab vendors for IEHP Members, and submitting complete lab results data to IEHP.

Lab results that are performed in the office (e.g., point of care HbA1c testing, urine tests, etc.) should be coded and submitted through Providers' encounter data.

Immunizations

To maximize performance in immunization-based measures, **IEHP strongly encourages all Providers to report all immunizations via the California Immunization Registry (CAIR2)**. For more information on how to register for CAIR2, please visit *http://cairweb.org/*. IEHP is working closely with CAIR to establish a data sharing arrangement to be used in Global Quality P4P reporting.

Supplemental Data

What is Supplemental Data?

When services are not captured in traditional encounter data systems, other Supplemental Data sources may be used to collect information about services rendered to Members to support Quality Reporting.

When Supplemental Data may be needed

- For services that were provided prior to eligibility
- When a Provider has "proof-of-service" for a noted gap in care (e.g. cervical cancer screening, immunizations rendered by another provider)
- When Provider has "proof-of-service" for an eligible-population exclusion (e.g. total hysterectomy, bilateral mastectomy)

How to use Supplemental Data to support Global Quality P4P

Create an electronic log that includes minimum required data elements. See Appendix 6 for file layout requirements. Below is a listing of minimum data elements needed in a supplemental data log.

- Member ID
- Date of Service
- Provider Identification
- Provider Specialty
- Diagnosis Code(s) – if applicable
- Procedure Code(s)
- Lab Results – if applicable

Requirements for using Supplemental Data in Global Quality P4P Reporting

- The IPA must have clearly defined policies and procedures (in writing) that describe how Supplemental Data is collected, validated and used for P4P reporting
- Policies/procedures must be shared with IEHP and must be in place to validate quality / accuracy of Supplemental Data
- The IPA must collect "proof-of-service" documentation to confirm all services that are reported in the Supplemental Data log
- The IPA must receive approval from IEHP's Quality Team to use Supplemental Data in Global Quality Reporting (deadline for approval is October 31, 2018)
- The IPA must complete a P4P Roadmap no later than December 1, 2018
- The IPA must complete IPA data validation activities prior to submitting Supplemental Data to IEHP
- The IPA must submit a final Supplemental Data log to IEHP via SFTP no later than February 1, 2019

Data Validation Requirements for Supplemental Data in Global Quality P4P Reporting

- To be counted in final IPA Global Quality P4P rates, Supplemental Data file must pass IEHP's independent HEDIS® audit process
- The IPA must present "proof-of-service" documents within required timeframes when requested by IEHP's auditors
- An auditor review will compare "proof-of-service" documents to submitted data
- Supplemental Data records must pass 100 percent validation to be included in the final P4P reporting

Financial Overview

Providers are eligible to receive financial rewards for performance excellence and for performance improvement. Financial rewards are based on a tiered system, providing increasing financial rewards for reaching higher tiered level performance. The 2018 GQ P4P Program incentive pool is $20 million for the IPA Program. Incentive dollars for the 2018 performance period will be distributed monthly via a new monthly per Member per month (PMPM) Quality Payment beginning in July 2019 and continuing through June 2020.

IPA Encounter Data Gates

IPA encounter data submissions must meet minimum adequacy requirements in order to receive GQ P4P Program incentive dollars. IPA encounter data performance is based on all professional encounters submitted by the IPA for services rendered during the measurement year (e.g., 2018 dates of service). IPA encounter data volume will be compared to established encounter data benchmarks for Seniors and Persons with Disabilities (SPD) and Non-SPD Members. IPA performance will be calculated against each IPA's proportion of SPD and Non-SPD Members.

Encounter data benchmarks have been established and correspond to an Encounter Data Gate, reflecting higher encounter data volumes. As IPAs reach higher levels of encounter data performance, they become eligible for a larger percentage of the total possible GQ P4P incentive. Encounter rates are expressed as the number of encounters per Member per year (PMPY). An encounter is defined as a unique visit per Member per Provider per day. The table below describes the Encounter Data Gates, performance levels, and their impact to IPA GQ P4P Program incentive payments.

PERCENT OF POSSIBLE INCENTIVE PAYMENT	ENCOUNTER DATA GATE	NON-SPD PMPY	SPD PMPY
50%	Gate 1	3.0	9.0
75%	Gate 2	4.0	11.0
100%	Gate 3	5.0	13.0

The Encounter Data Gating methodology only applies to the IPA methodology. Encounter data must be submitted to IEHP in a timely way and must adhere to the reporting timeframes delineated in IEHP's Provider Policy and Procedure Manual - Policy 21A.

Performance Measures

Appendix 1 provides a list of the 23 measures included in the 2018 GQ P4P Program and includes the thresholds and benchmarks associated with respective tier goals. These measures have been categorized into four domains: *Clinical Quality; Behavioral Health Integration; Patient Experience; Encounter Data*.

Most measures included in the *Clinical Quality Domain* primarily use standard Healthcare Effectiveness Data and Information Set (HEDIS®) process and outcomes measures that are based on the specifications published by the National Committee for Quality Assurance (NCQA). Non-HEDIS® measures that are included in the Clinical Quality Domain come from the California Department of Health Care Services (DHCS) Medi-Cal Managed Care Quality Program and the Pharmacy Quality Alliance (PQA).

Clinical Quality Domain Measures:

- Avoidance of Antibiotic Treatment in Adults with Acute Bronchitis (New)
- Breast Cancer Screening
- Cervical Cancer Screening
- Childhood Immunizations – Combo 10
- Comprehensive Diabetes Care – Eye Exam
- Comprehensive Diabetes Care – HbA1c Control < 8
- Concurrent Use of Opioids and Benzodiazepines (New)
- Immunizations for Adolescents – Combo 2
- Initial Health Assessment
- Medication Management for People with Asthma – 75% rate
- Timely Postpartum Care
- Timely Prenatal Care
- Weight Assessment and Counseling for Nutrition and Physical Activity for Children and Adolescents (New)
    - Counseling for Physical Activity
    - Counseling for Nutrition
    - BMI Percentile
- Well-Child 3-6 Years of Life

IEHP's HEDIS® 2019 data set (measurement year 2018) will be used to evaluate Providers' year-end performance. This measure set undergoes an independent audit review prior to rate finalization.

The Initial Health Assessment (IHA) measure follows IEHP's IHA internal compliance monitoring methodology and is not a HEDIS® measure.

The Concurrent Use of Opioids and Benzodiazepines measure specification is developed and maintained by the PQA. This measure will not be used for incentive calculations but will be collected to establish a baseline rate for 2018. See Appendix 2 for measure details.

Behavioral Health Integration Domain Measures:

The Behavioral Health Integration Domain includes two measures derived from the Centers for Medicare and Medicaid Services (CMS) Physician Quality Reporting System (PQRS) measure set.[1]

- Screening for Clinical Depression in Primary Care
- Positive Depression Screening with Follow-Up Plan

Patient Experience Domain Measures:

Patient Experience Domain measures include Member Satisfaction Survey questions from the Consumer Assessment of Healthcare Providers and Systems (CAHPS) survey that is published by the Agency for Healthcare Research and Quality (AHRQ). IEHP conducts a Member Satisfaction Survey that is a modified CAHPS survey and is the sole data source supporting the performance scoring methodology for this measure domain. The IEHP Member Satisfaction Survey is conducted between June and December of each year. Surveys received from the 2018 Member Satisfaction Survey will be used to calculate the Patient Experience Domain measures. A copy of the current Member Satisfaction Survey is included in Appendix 4.

- Access to Care Needed Right Away
- Access to Routine Care
- Coordination of Care

Encounter Data Domain Measures:

The fourth measure domain is *Encounter Data*. IPAs eligible for the GQ P4P Program become eligible to receive payment dollars once they have met the minimum encounter data gate. Higher encounter gate performance qualifies an IPA to receive a higher percentage of incentive dollars. See the 'IPA Encounter Data Gates' section of this program guide for additional details on this methodology.

[1] For information on the PQRS measure set: https://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/PQRS/index.html.

2018 IPA Global Quality P4P Scoring and Payment Flowchart

PROGRAM ELIGIBILITY REQUIREMENTS

Membership will be determined as of 01/2018

IPAs with 5,000 or more assigned Members

SCORING METHOD

Incentive eligible IPAs will receive a Quality Score for each Measure

IPAs must have 30 or more Members in each measure to be eligible for a Quality Score

The Quality Score is averaged to determine the Global Quality Performance Score

At least three measures are required to determine the Global Quality Performance Score

IPA PAYMENT CALCULATION

[Global Quality Performance Score] x [# Medi-Cal average Member months] = Member Points

[Member Points] x [payment amount per Member pint] = Max Payment Amount

[Max Payment Amount] x [Encounter Gate %] = Final Payment Amount

Scoring Methodology

Payment will be awarded to IPAs based on individual performance in reaching established Quality Goals (e.g., Tier Goals for each measure).

In the *Clinical Quality Domain,* HEDIS® measure results are based on each measure's total eligible population assigned to the IPA. The eligible population is defined as the set of Members that meet the denominator criteria specified in the current year's HEDIS® Technical Specifications (Volume 2) published by NCQA. Members in the eligible population are attributed to the assigned PCP on the anchor date of each measure, as defined within the HEDIS® measure. Members contribute to a IPA's HEDIS® measure denominator if continuous enrollment criteria are met at the health plan level. For each measure, the HEDIS® score reflects the proportion of the eligible population that is in compliance with the numerator criteria, as defined in the current HEDIS® technical specifications (Volume 2).

In the *Clinical Quality Domain*, Non-HEDIS® measure results (i.e., Initial Health Assessment) are based on new health plan Members who are assigned to the IPA during the measurement year and who remain enrolled with IEHP and the IPA through the 120 day post enrollment period.
See Appendix 2 for measure details.

In the *Patient Experience Domain*, monthly Member Satisfaction Survey measures are based on Members who meet eligibility criteria to receive a mailed survey between June and December of the measurement year. Members eligible to receive a Member Satisfaction Survey must have been continuously enrolled with IEHP for at least six months in the measurement year (2018) and must have had an office visit in the prior six months, based on encounter data submitted to IEHP. Members who meet the survey eligibility criteria are randomly sampled to receive a survey. Survey measure results are attributed to the Member's assigned IPA based on the most recent encounter that qualified the Member for the survey. A Member is eligible to receive only one survey per calendar year.

For IPAs, the *Encounter Data Domain* measures assess the volume of IPA encounters received for all assigned IPA Members. The denominator is all assigned Medi-Cal Members each month of the measurement year (2018). All monthly assigned Members are summed to create the denominator (i.e., Member months). The numerator is the sum of all unique encounters (e.g., unique Member, Provider, date of service) in the measurement year for all assigned Members in the denominator. A Per Member Per Year (PMPY) rate is calculated following this formula:

(Total Unique Encounters / Total Member Months) x 12 = PMPY

Payment Methodology

IPA performance for each quality measure will be given a point value (i.e., a Quality Score). Points are assigned based on the Tier Goal achieved (e.g., Tier 1 = one point, Tier 2 = two points, Tier 3 = three points) for each measure.

IPAs that have at least three quality measures which meet the minimum denominator size (n = 30) will be considered for payment calculations. An average of all eligible Quality Scores will determine the overall GQ Performance Score. GQ P4P Program payments will be awarded according to the following formula:

[Global Quality Performance Score] x [# Medi-Cal Average Member Months] = ***Member Points***

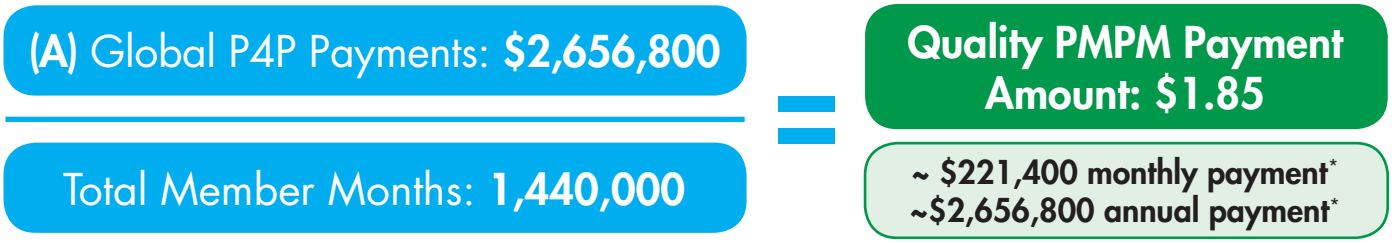
[Member Points] x [Payment Amount per Member Point] = ***Incentive Payout Total***

The payment amount per Member point is dependent on the total incentive money available for IPAs.

IPA PMPM Quality Payment Methodology

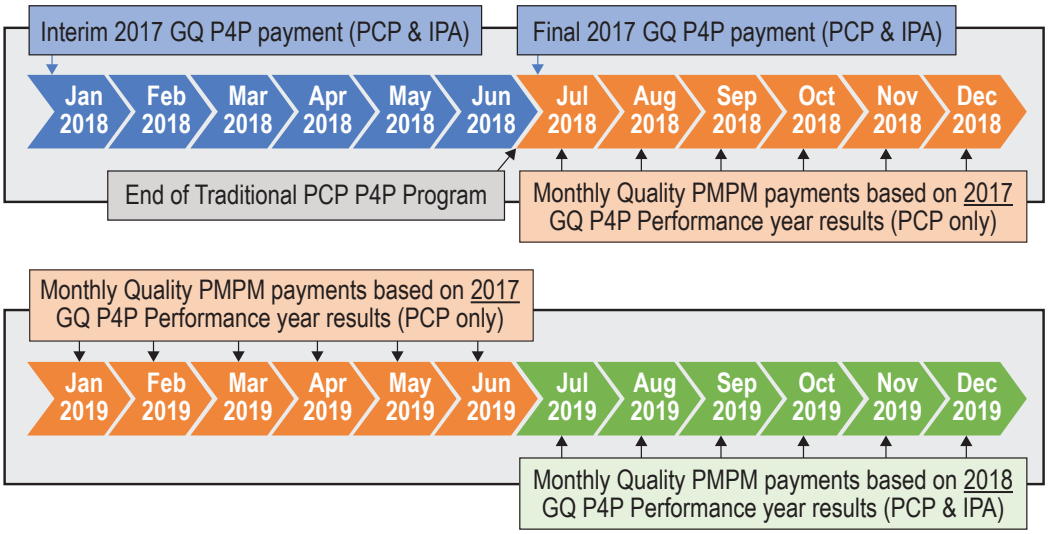
From July 2019 – June 2020, IPAs will receive a monthly PMPM (per member per month) quality payment based on 2018 GQ P4P performance using the following formula:

IPA payment example: *IPA with monthly average of 120,000 Members (1,440,000 Member Months), 2.0 GQ Quality Score and Encounter Data Gate 2 met*



**assuming stable membership volume*

Quality Incentive Payout Timeline: Provider Communication Timeline



Getting Help

Please direct questions and/or comments related to this program to IEHP's Provider Call Center at 909-890-2054 or to IEHP's Quality Department at ***QualityPrograms@iehp.org***.

Program Terms and Conditions

- Participation in IEHP's GQ P4P Program, as well as acceptance of incentive payments, does not in any way modify or supersede any terms or conditions of any agreement between IEHP and Providers or IPAs, whether that agreement is entered into, prior to or subsequent to, the date of this communication.
- There is no guarantee of future funding for, or payment under, any IEHP Provider incentive program. The IEHP GQ P4P Program and/or its terms and conditions may be modified or terminated at any time, with or without notice, at IEHP's sole discretion.
- Criteria for calculating incentive payments are subject to change at any time, with or without notice, at IEHP's sole discretion.
- In consideration of IEHP's offering of the IEHP GQ P4P Program, participants agree to fully and forever release and discharge IEHP from any and all claims, demands, causes of action, and suits, of any nature, pertaining to or arising from the offering by IEHP of the IEHP GQ P4P Program.
- The determination of IEHP regarding performance scoring and payments under the IEHP GQ P4P Program is final.
- As a condition of receiving payment under the IEHP GQ P4P Program, Providers and IPAs must be active and contracted with IEHP and have active assigned Members at the time of payment.

APPENDIX 1: *2018 IPA Global Quality P4P Program Measures*

2018 GQ P4P PROGRAM MEASURE LIST					
Domain	**Measure Name**	**Population**	**Tier 1**	**Tier 2**	**Tier 3[2]**
Clinical Quality	Avoidance of Antibiotic Treatment in Adults with Acute Bronchitis [1]	Adult	Improvement demonstrated by meeting the following 2 conditions: 10% reduction in non-compliance AND Improvement of at least 2.0 percentage points	Improvement demonstrated by meeting the following 2 conditions: 20% reduction in non-compliance AND Improvement of at least 3.0 percentage points	39.0%
Clinical Quality	Comprehensive Diabetes Care - HbA1c Control <8	Adult			58.0%
Clinical Quality	Comprehensive Diabetes Care - Eye Exam	Adult			68.0%
Clinical Quality	Medication Management for People with Asthma - 75%	Adult			48.0%
Behavioral Health Integration	Screening for Clinical Depression in Primary Care	Adult and Adolescent			50.0%
Behavioral Health Integration	Positive Depression Screening with Follow-Up Plan	Adult and Adolescent			90.0%
Clinical Quality	Breast Cancer Screening	Women			71.0%
Clinical Quality	Cervical Cancer Screening	Women			70.0%
Clinical Quality	Timeliness of Prenatal Care	Women			91.0%
Clinical Quality	Postpartum Care	Women			74.0%
Clinical Quality	Childhood Immunizations - Combo 10	Child	Improvement demonstrated by meeting the following 2 conditions: 10% reduction in non-compliance AND Improvement of at least 2.0 percentage points	Improvement demonstrated by meeting the following 2 conditions: 20% reduction in non-compliance AND Improvement of at least 3.0 percentage points	46.0%
Clinical Quality	Immunizations for Adolescents - Combo 2	Child			32.3%
Clinical Quality	Well-Child Visits 3-6 Years of Life	Child			83.0%
Clinical Quality	Weight Assessment and Counseling for Nutrition and Physical Activity for Children and Adolescents - Counseling for Physical Activity [1]	Child			72.0%
Clinical Quality	Weight Assessment and Counseling for Nutrition and Physical Activity for Children and Adolescents - Counseling for Nutrition [1]	Child			80.0%
Clinical Quality	Weight Assessment and Counseling for Nutrition and Physical Activity for Children and Adolescents - BMI Percentile [1]	Child			86.0%
Clinical Quality	Initial Health Assessment	All			50.0%
Clinical Quality	Concurrent Use of Opioids and Benzodiazepines [1] **	All	Baseline Reporting Year		
Patient Experience	Member Satisfaction Survey - Access to Care Needed Right Away	All	84.00%	86.00%	88.0%
Patient Experience	Member Satisfaction Survey - Coordination of Care	All	82.00%	84.00%	86.0%
Patient Experience	Member Satisfaction Survey – Access to Routine Care	All	82.00%	85.00%	86.0%
Encounter Data	Encounter Data for PCPs PMPY – SPD***	All	9.0	11.0	13.0
Encounter Data	Encounter Data for PCPs PMPY - Non-SPD***	All	3.0	4.0	5.0

*[1] New Measure for 2018 [2] Tier 3 goals set at the 90th percentile as published in the NCQA 2017 Mid-year Benchmarks and Thresholds and 2016 HEDIS® and Exclusion Audit Means, Percentiles source files ** Reporting Only Measure. Not eligible for incentive dollars*
*** Encounter Data measure benchmarks are "gates" not "tiers"*

APPENDIX 2: *Measures Overview*

Population: Adult

Avoidance of Antibiotic Treatment in Adults With Acute Bronchitis (AAB)

Methodology: HEDIS®

Measure Description: The percentage of adults 18-64 years of age with a diagnosis of acute bronchitis who were not dispensed an antibiotic prescription on or three days after the Index Episode Start Date (IESD).

- Episode Date is the date of service for any outpatient or emergency department (ED) visit during the Intake Period (January 1, 2018-December 24, 2018) with a diagnosis of acute bronchitis
- IESD: the earliest Episode Date during the Intake Period with a diagnosis of acute bronchitis that meets all of the following criteria:
    1. Episode Date is the date of service for any outpatient or ED visit during the Intake Period with a diagnosis of acute bronchitis.
    2. A 30-day Negative Medication History prior to the Episode Date.
    3. A 12-month Negative Comorbid Condition History prior to and including the Episode Date.
    4. A Negative Competing Diagnosis during the 38-day period from 30 days prior to the Episode Date through seven days after the Episode Date.
    5. The member was continuously enrolled one year prior to the Episode Date through seven days after the Episode Date.
- The measure is reported as an inverted rate [1 – (numerator/eligible population)]. A higher rate indicates appropriate treatment of adults with acute bronchitis (i.e., the proportion for whom antibiotics were not prescribed).
- Members in hospice are excluded from the eligible population.
- Exclude denied claims when assessing numerator criteria.
- Do not include ED visits or observation visits that result in an inpatient stay. When an ED or observation visit and an inpatient stay are billed on separate claims, the visit results in an inpatient stay when the admission date for the inpatient stay occurs on the ED/observation date of service or one calendar day after. An ED or observation visit billed on the same claim as an inpatient stay is considered a visit that resulted in an inpatient stay.

Denominator: Members 18-64 years of age, who had an outpatient visit, an observation visit or an ED visit between January 1 – December 24 of the measurement year (2018) with a diagnosis of acute bronchitis.

Numerator: Dispensed prescription for an antibiotic medication on or three days after IESD for the Members in denominator.

AAB ANTIBIOTIC MEDICATIONS			
Description	**Prescription**		
Aminoglycosides	• Amikacin • Gentamicin	• Tobramycin • Streptomycin	
Aminopenicillins	• Amoxicillin	• Ampicillin	
Beta-lactamase inhibitors	• Amoxicillin-clavulanate • Ticarcillin-clavulanate	• Piperacillin-tazobactam • Ampicillin-sulbactam	
First-generation cephalosporins	• Cefadroxil	• Cefazolin	• Cephalexin
Fourth-generation cephalosporins	• Cefepime		
Ketolides	• Telithromycin		
Lincomycin derivatives	• Clindamycin	• Lincomycin	
Macrolides	• Azithromycin • Clarithromycin	• Erythromycin • Erythromycin ethylsuccinate	• Erythromycin lactobionate • Erythromycin stearate
Miscellaneous antibiotics	• Aztreonam • Chloramphenicol • Dalfopristin-quinupristin	• Daptomycin • Erythromycin-sulfisoxazole	• Metronidazole • Vancomycin • Linezolid
Natural penicillins	• Penicillin G benzathine-procaine • Penicillin G potassium	• Penicillin G procaine • Penicillin G sodium	• Penicillin V potassium • Penicillin G benzathine
Penicillinase resistant penicillins	• Dicloxacillin	• Nafcillin	• Oxacillin
Quinolones	• Ciprofloxacin • Gemifloxacin	• Levofloxacin • Moxifloxacin	• Norfloxacin • Ofloxacin
Rifamycin derivatives	• Rifampin		
Second-generation cephalosporin	• Cefaclor • Cefotetan	• Cefoxitin • Cefprozil	• Cefuroxime
Sulfonamides	• Sulfadiazine	• Sulfamethoxazole-trimethoprim	
Tetracyclines	• Doxycycline	• Minocycline	• Tetracycline
Third-generation cephalosporins	• Cefdinir • Cefditoren • Cefixime	• Cefotaxime • Cefpodoxime • Ceftazidime	• Ceftibuten • Ceftriaxone
Urinary anti-infectives	• Fosfomycin • Nitrofurantoin • Trimethoprim	• Nitrofurantoin macrocrystals-monohydrate • Nitrofurantoin macrocrystals	

Comprehensive Diabetes Care (CDC) – HbA1c Control (<8.0)

Methodology: HEDIS®

Measure Description: The percentage of Members 18-75 years of age with diabetes (type 1 and type 2) who had the following:

- HbA1c Control (<8.0%) – This includes diabetics whose most recent HbA1c test during the measurement year (2018) has a value <8.0%.
  - The Member is not numerator compliant if the result for the most recent HbA1c test is ≥8.0% or is missing a result, or if an HbA1c test was not done during the measurement year (2018).
- The eligible population in this measure meets all of the following criteria:
  1. Members who are 18-75 years old as of December 31 of the measurement year (2018).
  2. Continuous enrollment in the measurement year (2018) with no more than one gap of up to 45 days during the measurement year.
  3. Members who meet any of the following criteria during the measurement year (2018) or the year prior to the measurement year (2017). Count services that occur over both years:
     - At least two outpatient visits, observation visits, ED visits or nonacute inpatient encounters on different dates of service, with a diagnosis of diabetes. Visit type need not be the same for the two visits.
     - At least one acute inpatient encounter with a diagnosis of diabetes.
     - Members who were dispensed insulin or hypoglycemics/ antihyperglycemics on an ambulatory basis during the measurement year (2018) or the year prior to the measurement year (2017).

CODES TO IDENTIFY HbA1c TESTS			
Service	**Code Type**	**Code**	**Code Description**
HbA1c Test (<7.0%)	CPT-CAT-II	3044F	Hg A1c Level Lt 7.0%
HbA1c Test	CPT	83036	Hemoglobin Glycated
HbA1c Test	CPT	83037	Hemoglobin; glycosylated (A1C) by device cleared by FDA for home use
HbA1c Test	CPT-CAT-II	3044F	Most recent hemoglobin A1c (HbA1c) level < 7.0%
HbA1c Test	CPT-CAT-II	3045F	Most recent hemoglobin A1c (HbA1c) level 7.0-9.0%
HbA1c Test	CPT-CAT-II	3046F	Most recent hemoglobin A1c (HbA1c) level > 9.0%
HbA1c Test	LOINC	17856-6	Hemoglobin A1c/hemoglobin.total In Blood By Hplc
HbA1c Test	LOINC	4548-4	Hemoglobin A1c/hemoglobin.total In Blood
HbA1c Test	LOINC	4549-2	Hemoglobin A1c/hemoglobin.total In Blood By Electrophoresis

- Members who meet any of the following criteria are excluded:
    1. Members in hospice
    2. Members who did not have a diagnosis of diabetes, in any setting, during the measurement year (2018) or the year prior to the measurement year (2017) and who had a diagnosis of gestational diabetes or steroid-induced diabetes, in any setting, during the measurement year (2018) or the year prior to the measurement year (2017)

Denominator: Members 18-75 years of age who meet all the criteria for eligible population.

Numerator: Members in the denominator who had the most recent HbA1c level <8 during the measurement year (2018).

Comprehensive Diabetes Care (CDC) – Eye Exam

Methodology: HEDIS®

Measure Description: The percentage of Members 18-75 years of age with diabetes (type 1 and type 2) who had the following:

- Eye Exam (retinal) performed – This includes diabetics who had one of the following:
  - A retinal or dilated eye exam by an eye care professional (optometrist or ophthalmologist) in the measurement year (2018)
  - A negative retinal or dilated eye exam (negative for retinopathy) by an eye care professional in the year prior to the measurement year (2018)
- The eligible population in this measure meets all of the following criteria:
  1. Members who were 18-75 years old as of December 31 of the measurement year (2018).
  2. Continuous enrollment in the measurement year (2018) with no more than one gap of up to 45 days during the measurement year.
  3. Members who meet any of the following criteria during the measurement year (2018) or the year prior to the measurement year (2017). Count services that occur over both years:
     - At least two outpatient visits, observation visits, ED visits or nonacute inpatient encounters on different dates of service, with a diagnosis of diabetes. Visit type need not be the same for the two visits.
     - At least one acute inpatient encounter with a diagnosis of diabetes.
     - Members who were dispensed insulin or hypoglycemics/ antihyperglycemics on an ambulatory basis during the measurement year (2018) or the year prior to the measurement year (2017).

CODES TO IDENTIFY EYE EXAMS			
Service	**Code Type**	**Code**	**Code Description**
Diabetic Retinal Screening	CPT	67028	Intravitreal Injection Of A Pharmacologic Agent (separate Procedure)
Diabetic Retinal Screening	CPT	67030	Discission Of Vitreous Strands (without Removal) Pars Plana Approach
Diabetic Retinal Screening	CPT	67031	Severing Of Vitreous Strands Vitreous Face Adhesions Sheets Membranes Or Opacities Laser Surgery (one Or More Stages)
Diabetic Retinal Screening	CPT	67036	Vitrectomy Mechanical Pars Plana Approach
Diabetic Retinal Screening	CPT	67039	Vitrectomy Mechanical Pars Plana Approach With Focal Endolaser Photocoagulation
Diabetic Retinal Screening	CPT	67040	Vitrectomy Mechanical Pars Plana Approach With Endolaser Panre Tinal Photocoagulation
Diabetic Retinal Screening	CPT	67041	Vitrectomy Mechanical Pars Plana Approach With Removal Of Preretinal Cellular Membrane (eg Macular Pucker)
Diabetic Retinal Screening	CPT	67042	Vitrectomy Mechanical Pars Plana Approach With Removal Of Internal Limiting Membrane Of Retina (eg For Repair Of Macular Hole
Diabetic Retinal Screening	CPT	67043	Vitrectomy mechanical pars plana approach, with removal of subretinal membrane (eg, Choroidal Neovascularization), includes, if performed, intraocular tamponade (ie, air, gas or silicone oil)
Diabetic Retinal Screening	CPT	67101	Repair Retinal Detachment, Incld Drainage Of Subretinal Fluid When Performed; Cryotherapy
Diabetic Retinal Screening	CPT	67105	Repair Retinal Detachment, Incld Drainage Of Subretinal Fluid When Performed; Photocoagulation
Diabetic Retinal Screening	CPT	67107	Repair Of retinal detachment scleral buckling (such as lamellar scleral dissection, Imbrication or encircling procedure), including, when performed, implant, cryotherapy, photocoagulation, and drainage of subretinal fluid
Diabetic Retinal Screening	CPT	67108	Repair Of Retinal Detachment With Vitrectomy Any Method With OR Without Air Or Gas Tamponade Focal Endolaser Photocoagulation
Diabetic Retinal Screening	CPT	67110	Repair Of Retinal Detachment By Injection Of Air Or Other Gas (e G Pneumatic Retinopexy)
Diabetic Retinal Screening	CPT	67112	Repair Of Retinal Detachment By Scleral Buckling Or Vitrectomy On Patient Having Previous Ipsilateral Retinal Detachment Repair
Diabetic Retinal Screening	CPT	67113	Repair Of Complex Retinal Detachment (eg, Proliferative Vitreoretinopathy Stage C-1 or greater, diabetic Traction Retinal Detachment, retinopathy of prematurity, retinal tear of greater than 90 degrees), with vitrectomy and membrane peeling, including, when performed, air, gas, or silicone oil tamponade, cryotherapy, endolaser photocoagulation, drainage of subretinal fluid, scleral buckling, and/or removal of lens
Diabetic Retinal Screening	CPT	67121	Removal Of Implanted Material Posterior Segment Intraocular

CODES TO IDENTIFY EYE EXAMS			
Service	**Code Type**	**Code**	**Code Description**
Diabetic Retinal Screening	CPT	67141	Prophylaxis Of Retinal Detachment (eg, retinal break lattice degeneration) without drainage, 1 or more sessions; cryotherapy, diathermy
Diabetic Retinal Screening	CPT	67145	Prophylaxis Of Retinal Detachment (eg, retinal break lattice degeneration) without drainage, 1 or more sessions; photocoagulation (laser or xenon arc)
Diabetic Retinal Screening	CPT	67208	Destruction Of Localized Lesion Of Retina (eg Macular Edema Tumors) One Or More Sessions Cryotherapy Diathermy
Diabetic Retinal Screening	CPT	67210	Destruction Of Localized Lesion Of Retina (eg Macular Edema Tumors) One Or More Sessions Photocoagulation
Diabetic Retinal Screening	CPT	67218	Destruction Of Localized Lesion Of Retina (eg Macular Edema Tumors) One Or More Sessions Radiation By Implantation Of Source
Diabetic Retinal Screening	CPT	67220	Destruction Of Localized Lesion Of Choroid (eg Choroidal Neovasc Ularization) Photocoagulation (eg Laser) One Or More Sessions
Diabetic Retinal Screening	CPT	67221	Destruction Of Localized Lesion Of Choroid (eg Choroidal Neovasc Ularization) Photodynamic Therapy (includes Intravenous Infusion
Diabetic Retinal Screening	CPT	67227	Destruction Of Extensive Or Progressive Retinopathy (eg Diabetic Retinopathy) One Or More Sessions Cryotherapy Diathermy
Diabetic Retinal Screening	CPT	67228	Destruction of extensive or progressive retinopathy (eg, Diabetic Retinopathy), 1 or more sessions; Photocoagulation
Diabetic Retinal Screening	CPT	92002	Ophthalmological services: medical examination and evaluation with initiation of diagnostic and treatment program; Intermediate, new patient
Diabetic Retinal Screening	CPT	92004	Ophthalmological services: medical examination and evaluation with initiation of diagnostic and treatment program; comprehensive, new patient, 1 or more visits
Diabetic Retinal Screening	CPT	92012	Ophthalmological services: medical examination and evaluation with initiation or continuation of diagnostic and treatment program; intermediate, established patient
Diabetic Retinal Screening	CPT	92014	Ophthalmological services: medical examination and evaluation with initiation or continuation of diagnostic and treatment program; comprehensive, established patient, 1 or more visits
Diabetic Retinal Screening	CPT	92018	Ophthalmological examination and evaluation under general anesthesia with or without manipulation of globe for passive range of motion or other manipulation to facilitate diagnostic examination; complete
Diabetic Retinal Screening	CPT	92019	Ophthalmological examination and evaluation under general anesthesia with or without manipulation of globe for passive range of motion or other manipulation to facilitate diagnostic examination; limited
Diabetic Retinal Screening	CPT	92134	Scanning computerized ophthalmic diagnostic imaging posterior segment, with interpretation and report, unilateral or bilateral: optic nerve
Diabetic Retinal Screening	CPT	92225	Ophthalmoscopy extended with retinal drawing (eg, for retinal detachment melanoma), with Interpretation and report; initial

Diabetic Retinal Screening	CPT	92250	Fundus Photography With Interpretation And Report
Diabetic Retinal Screening	CPT	92260	Ophthalmodynamometry
Diabetic Retinal Screening	CPT	99203	Office or other patient visit for the evaluation and management of a new patient, which requires these 3 key components: A detailed history: A detailed exam: Medical decision making of low complexity.
Diabetic Retinal Screening	CPT	99204	Office or other patient visit for the evaluation and management of a new patient, which requires these 3 key components: A comprehensive history: A comprehensive exam: Medical decision making of moderate complexity.
Diabetic Retinal Screening	CPT	99205	Office or other patient visit for the evaluation and management of a new patient, which requires these 3 key components: A comprehensive history: A comprehensive exam: Medical decision making of high complexity.
Diabetic Retinal Screening	CPT	99213	Office or other patient visit for the evaluation and management of an established patient, which requires at least 2 of these 3 components: An expanded problem focused history: An expanded problem focused examination: Medical decision making of low complexity.
Diabetic Retinal Screening	CPT	99214	Office or other patient visit for the evaluation and management of an established patient, which requires at least 2 of these 3 components: A detailed history: A detailed exam: Medical decision making of moderate complexity.
Diabetic Retinal Screening	CPT	99215	Office or other patient visit for the evaluation and management of an established patient, which requires at least 2 of these 3 components: A comprehensive history: A comprehensive exam: Medical decision making of high complexity.

CODES TO IDENTIFY EYE EXAMS			
Service	**Code Type**	**Code**	**Code Description**
Diabetic Retinal Screening	CPT	99242	Office consultation for a new or established patient which requires these 3 key components: An expanded problem focused history: An expanded problem focused examination: and, Straightforward medical decision making.
Diabetic Retinal Screening	CPT	99243	Office consultation for a new or established patient which requires these 3 key components: A detailed history: A detailed exam: and, Medical decision making of low complexity.
Diabetic Retinal Screening	CPT	99244	Office consultation for a new or established patient which requires these 3 key components: A comprehensive history: A comprehensive examination: and, Medical decision making of moderate complexity.
Diabetic Retinal Screening	CPT	99245	Office consultation for a new or established patient which requires these 3 key components: A comprehensive history: A comprehensive examination: and, Medical decision making of high complexity.
Diabetic Retinal Screening	HCPCS	S0620	Routine Ophthalmological Examination Including Refraction; New Patient (s0620)
Diabetic Retinal Screening	HCPCS	S0621	Routine Ophthalmological Examination Including Refraction; Established Patient (s0621)
Diabetic Retinal Screening	HCPCS	S3000	Diabetic Indicator; Retinal Eye Exam, Dilated, Bilateral (s3000)

- Members who meet any of the following criteria are excluded:
    1. Members in hospice
    2. Members who did not have a diagnosis of diabetes, in any setting, during the measurement year (2018) or the year prior to the measurement year (2017) and who had a diagnosis of gestational diabetes or steroid-induced diabetes, in any setting, during the measurement year or the year prior to the measurement year

Denominator: Members 18-75 years of age who meet all the criteria for eligible population.

Numerator: Members in the denominator who had an eye exam during the measurement year (2018).

Medication Management for People with Asthma – 75% rate (MMA)

Methodology: HEDIS®

Measure Description: The percentage of Members 5–64 years of age during the measurement year (2018) who were identified as having persistent asthma and were dispensed appropriate medications which they remained on for at least 75 percent of their treatment period. (Treatment Period: The period of time beginning on the Index Prescription Start Date through December 31, 2018.)

- Eligible population in this measure meets all of the following criteria:
  1. Age 5- 64 as of December 31 of the measurement year (2018).
  2. Continuous enrollment during the measurement year (2018) and the year prior to the measurement year (2017) with no more than one gap in enrollment of up to 45 days during each year of continuous enrollment.
  3. Members had a) At least one ED visit with a principal diagnosis of asthma, OR b) At least one acute inpatient encounter with a principal diagnosis of asthma, OR c) At least four outpatient visits or observation visits on different dates of service, with any diagnosis of asthma and at least two asthma medication dispensing events for any controller medication or reliever medication. Visit type need not be the same for the four visits, OR d) At least four asthma medication dispensing events for any controller medication or reliever medication.

ASTHMA CONTROLLER MEDICATIONS:			
Description	**Prescription**		
Antiasthmatic combinations	• Dyphylline-guaifenesin	• Guaifenesin-theophylline	
Antibody inhibitors	• Omalizumab		
Anti-interleukin-5	• Mepolizumab	• Reslizumab	
Inhaled steroid combinations	• Budesonide-formoterol • Fluticasone-salmeterol	• Fluticasone-vilanterol • Mometasone-formoterol	
Inhaled corticosteroids	• Beclomethasone • Budesonide • Ciclesonide	• Flunisolide • Fluticasone CFC free • Mometasone	
Leukotriene modifiers	• Montelukast	• Zafirlukast	• Zileuton
Mast cell stabilizers	• Cromolyn		
Methylxanthines	• Dyphylline	• Theophylline	

ASTHMA RELIEVER MEDICATIONS			
Description	**Prescriptions**		
Short-acting, inhaled beta-2 agonists	• Albuterol	• Levalbuterol	• Pirbuterol

- Members who meet any of the following criteria are excluded:
    1. Members who had no asthma controller medications dispensed during the measurement year (2018).
    2. Members in hospice are excluded.
    3. Members with the following diagnosis any time during the Member's history through December 31 of the measurement year (2018) are excluded: COPD, Acute Respiratory Failure, Cystic Fibrosis, Chronic respiratory conditions and Emphysema.

Denominator: Members 5–64 years of age during the measurement year (2018) who were identified as having persistent asthma and were dispensed appropriate medications which they remained on during the treatment period.

Numerator: Members in denominator who remained on an asthma controller medication for at least 75 percent of their treatment period.

Population: Adult and Adolescent

Screening for Clinical Depression in Primary Care

Methodology: IEHP-defined Quality Metric – Modified from PQRS measure (NQF 0418)

Measure Description: The percentage of Members aged 12 years and older screened for clinical depression on the date of the encounter using an age appropriate standardized depression screening tool during the measurement year (2018).

Denominator: All Members aged 12 years and older with a PCP visit in the measurement year (2018). Member counted only once in the denominator.

PRIMARY CARE PROVIDER VISIT CODES:			
Service	**Code Type**	**Code**	**Code Description**
Screening for Clinical Depression in Primary Care	CPT	99201	Office or other outpatient visit for the evaluation and management of a new patient which requires these three key components: A problem focused history; A problem focused examination; Straightforward medical decision making. Typically, 10 minutes are spent face-to-face with the patient and/or family.
Screening for Clinical Depression in Primary Care	CPT	99202	Office or other outpatient visit for the evaluation and management of a new patient which requires these three key components: An expanded problem focused history; An expanded problem focused examination; Straightforward medical decision making. Typically, 20 minutes are spent face-to-face with the patient and/or family.
Screening for Clinical Depression in Primary Care	CPT	99203	Office or other outpatient visit for the evaluation and management of a new patient which requires these three key components: A detailed history; A detailed examination; Medical decision making of low complexity. Typically, 30 minutes are spent face-to- face with the patient and/or family.
Screening for Clinical Depression in Primary Care	CPT	99204	Office or other outpatient visit for the evaluation and management of a new patient which requires these three key components: A comprehensive history; A comprehensive examination; Medical decision making of moderate complexity. Typically, 45 minutes are spent face-to-face with the patient and/or family.

PRIMARY CARE PROVIDER VISIT CODES:			
Service	**Code Type**	**Code**	**Code Description**
Screening for Clinical Depression in Primary Care	CPT	99205	Office or other outpatient visit for the evaluation and management of a new patient which requires these three key components: A comprehensive history; A comprehensive examination; Medical decision making of high complexity. Typically, 60 minutes are spent face-to-face with the patient and/or family.
Screening for Clinical Depression in Primary Care	CPT	99212	Office or other outpatient visit for the evaluation and management of an established patient which requires at least two of these 3 key components: A problem focused history; A problem focused examination; Straightforward medical decision making. Typically, 10 minutes are spent face-to-face with the patient and/or family.
Screening for Clinical Depression in Primary Care	CPT	99213	Office or other outpatient visit for the evaluation and management of an established patient which requires at least two of these 3 key components: An expanded problem focused history; An expanded problem focused examination; Medical decision making of low complexity. Typically, 15 minutes are spent face-to-face with the patient and/or family.
Screening for Clinical Depression in Primary Care	CPT	99214	Office or other outpatient visit for the evaluation and management of an established patient which requires at least two of these 3 key components: A detailed history; A detailed examination; Medical decision making of moderate complexity. Typically, 25 minutes are spent face-to-face with the patient and/or family.
Screening for Clinical Depression in Primary Care	CPT	99215	Office or other outpatient visit for the evaluation and management of an established patient which requires at least two of these 3 key components: A comprehensive history; A comprehensive examination; Medical decision making of high complexity. Typically, 40 minutes are spent face-to-face with the patient and/or family.
Screening for Clinical Depression in Primary Care	HCPCS	G0101	Office or other outpatient visit for the evaluation and management of an established patient which requires at least two of these 3 key components: A comprehensive history; A comprehensive examination; Medical decision making of high complexity. Typically, 40 minutes are spent face-to-face with the patient and/or family.
Screening for Clinical Depression in Primary Care	HCPCS	G0402	Initial preventive physical examination face-to-face visits services limited to new beneficiary during the first 12 months
Screening for Clinical Depression in Primary Care	HCPCS	G0438	Annual wellness visit includes a personalized prevention plan of service (pps) initial visit
Screening for Clinical Depression in Primary Care	HCPCS	G0439	Annual wellness visit includes a personalized prevention plan of service (pps) subsequent visit

PRIMARY CARE PROVIDER VISIT CODES:			
Service	**Code Type**	**Code**	**Code Description**
Screening for Clinical Depression in Primary Care	HCPCS	G0444	Annual depression screening 15 minutes
Screening for Clinical Depression in Primary Care	CPT	97003	Occupational therapy evaluation

Numerator: Members screened for clinical depression on the date of the encounter using an age appropriate standardized tool during the measurement year (2018).

CODES TO IDENTIFY SCREENING FOR CLINICAL DEPRESSION			
Service	**Code Type**	**Code**	**Code Description**
Screening for Clinical Depression in Primary Care	CPT	1220F	Patient screened for depression (sud)
Screening for Clinical Depression in Primary Care	CPT	3351F	Negative screen for depressive symptoms as categorized by using a standardized depression screening/ assessment tool (mdd)
Screening for Clinical Depression in Primary Care	CPT	3352F	No significant depressive symptoms as categorized by using a stan dardized depression assessment tool (mdd)
Screening for Clinical Depression in Primary Care	CPT	3353F	Mild to moderate depressive symptoms as categorized by using a standardized depression screening/ assessment tool (mdd)
Screening for Clinical Depression in Primary Care	CPT	3354F	Clinically significant depressive symptoms as categorized by usin g a standardized depression screening/assessment tool (mdd)
Screening for Clinical Depression in Primary Care	CPT	3725F	Screening for depression performed (dem)
Screening for Clinical Depression in Primary Care	HCPCS	G0444	Annual depression screening 15 minutes
Screening for Clinical Depression in Primary Care	HCPCS	G8431	Positive screen for clinical depression using a standardized tool and a follow-up plan documented
Screening for Clinical Depression in Primary Care	HCPCS	G8433	Screening for clinical depression using a standardized tool not documented patient not eligible/appropriate
Screening for Clinical Depression in Primary Care	HCPCS	G8510	Negative screen for clinical depression using a standardized tool patient not eligible/appropriate for follow-up plan documented
Screening for Clinical Depression in Primary Care	HCPCS	G8511	Screen for clinical depression using a standardize tool documented follow up plan not documented reason not specified
Screening for Clinical Depression in Primary Care	HCPCS	G8940	Screening for clinical depression documented follow-up plan not documented patient not eligible/ appropriate

Definitions:

Screening – Completion of a clinical or diagnostic tool used to identify people at risk of developing or having a certain disease or condition, even in the absence of symptoms.

Standardized Depression Screening Tool – A normalized and validated depression screening tool developed for the Member population in which it is being utilized. The name of the age appropriate standardized depression screening tool utilized must be documented in the medical record.

Examples of depression screening tools include but are not limited to:

- **Adolescent Screening Tools (12-17 years):** Patient Health Questionnaire for Adolescents (PHQ-A), Beck Depression Inventory-Primary Care Version (BDI-PC), Mood Feeling Questionnaire (MFQ), Center for Epidemiologic Studies Depression Scale (CES-D), and PRIME MD-PHQ2
- **Adult Screening Tools (18 years and older):** Patient Health Questionnaire (PHQ-9 or PHQ-2), Beck Depression Inventory (BDI or BDI-II), Center for Epidemiologic Studies Depression Scale (CES-D), Depression Scale (DEPS), Duke Anxiety-Depression Scale (DADS), Geriatric Depression Scale (GDS), Cornell Scale Screening, and PRIME MD-PHQ2

Positive Depression Screening with Follow Up Plan

Methodology: IEHP-defined Quality Metric – Modified from PQRS measure (NQF 0418)

Measure Description: The percentage of Members aged 12 years and older who screened positive for clinical depression using an age appropriate standardized depression screening tool who also have a follow-up plan documented during the measurement year (2018).

Denominator: All Members aged 12 years and older with a PCP visit with a positive depression screening in the measurement year (2018). Member counted only once in the denominator.

CODES TO IDENTIFY POSITIVE DEPRESSION SCREENING DURING A PRIMARY CARE PROVIDER VISIT:			
Service	**Code Type**	**Code**	**Code Description**
Positive Depression Screening with Follow Up Plan	CPT	3353F	Mild to moderate depressive symptoms as categorized by using a standardized depression screening/assessment tool (mdd)
Positive Depression Screening with Follow Up Plan	CPT	3354F	Clinically significant depressive symptoms as categorized by using a standardized depression screening/assessment tool (mdd)
Positive Depression Screening with Follow Up Plan	HCPCS	G8431	Positive screen for clinical depression using a standardized tool and a follow-up plan documented
Positive Depression Screening with Follow Up Plan	HCPCS	G8511	Screen for clinical depression using a standardize tool documented follow up plan not documented reason not specified
Positive Depression Screening with Follow Up Plan	HCPCS	G8940	Screening for clinical depression documented follow-up plan not documented patient not eligible/ appropriate

Numerator: Members screened positive for clinical depression with a follow-up plan documented during the measurement year (2018).

CODES TO IDENTIFY POSITIVE DEPRESSION SCREENING WITH FOLLOW-UP PLAN			
Service	**Code Type**	**Code**	**Code Description**
Positive Depression Screening with Follow Up Plan	CPT	0545F	Plan for follow-up care for major depressive disorder documented (mdd adol)
Positive Depression Screening with Follow Up Plan	HCPCS	G8431	Positive screen for clinical depression using a standardized tool and a follow-up plan documented
Positive Depression Screening with Follow Up Plan	HCPCS	G8940	Screening for clinical depression documented follow-up plan not documented patient not eligible/ appropriate

Definitions:

Follow-Up Plan – Documented follow-up for a positive depression screening ***must*** include one or more of the following:

- Additional evaluation for depression
- Suicide Risk Assessment
- Referral to a practitioner who is qualified to diagnose and treat depression
- Pharmacological interventions
- Other interventions or follow-up for the diagnosis or treatment of depression

Population: Women

Breast Cancer Screening (BCS)

Methodology: HEDIS®

Measure Description: The percentage of women 50–74 years of age who had a mammogram to screen for breast cancer any time on or between October 1 two years prior to the measurement year (2016) and December 31 of the measurement year (2018).

- The eligible population in the measure meets all of the following criteria:
  1. Women 52-74 years as of December 31 of the measurement year (2018).
  2. Continuous enrollment from October 1 two years prior to the measurement year (2016) through December 31 of the measurement year (2018) with no more than one gap in enrollment of up to 45 days for each calendar year of continuous enrolment. No gaps in enrollment are allowed from October 1 two years prior to the measurement year (2016) through December 31 two years prior to the measurement year (2016).

CODES USED TO IDENTIFY MAMMOGRAPHY:			
Service	**Code Type**	**Code**	**Code Description**
Breast Cancer Screening	CPT	77055	Mammography Unilateral
Breast Cancer Screening	CPT	77056	Mammography Bilateral
Breast Cancer Screening	CPT	77057	Screening Mammography Bilateral (2-view Film Study Of Each Breast)
Breast Cancer Screening	CPT	77061	Digital Breast Tomosynthesis Unilateral
Breast Cancer Screening	CPT	77062	Digital Breast Tomosynthesis Bilateral
Breast Cancer Screening	CPT	77063	Screening Digital Breast Tomosynthesis Bilateral (list Separately In Addition To Code For Primary Procedure)
Breast Cancer Screening	CPT	77065	Diagnostic Mammography W/computer-aided Detection; Unilateral
Breast Cancer Screening	CPT	77066	Diagnostic Mammography W/computer-aided Detection; Bilateral
Breast Cancer Screening	CPT	77067	Screening Mammography Bilateral (2-view Film Study Of Each Breast Including Computer-aided Detection (cad)
Breast Cancer Screening	HCPCS	G0202	Screening Mammography, Bilateral (2-view Study Of Each Breast), Including Computer-aided Detection (cad) When Performed (g0202)
Breast Cancer Screening	HCPCS	G0204	Diagnostic Mammography, Including Computer-aided Detection (cad) When Performed; Bilateral (g0204)
Breast Cancer Screening	HCPCS	G0206	Diagnostic Mammography, Including Computer-aided Detection (cad) When Performed; Unilateral (g0206)

- Members who meet any of the following criteria are excluded:
    1. Members who have had a bilateral mastectomy anytime during their history through December 31, 2018 may be excluded.

       To exclude Members who meet the exclusion criteria, please complete Member Historical Data Form and fax to IEHP's Quality Informatics Team at: 909-477-8568.

       A copy of the Historical Data Form is available in Appendix 3.

    2. Members in hospice are excluded.

Denominator: Women 52-74 years of age who met the criteria for eligible population.

Numerator: Members in denominator who had one or more mammograms any time on or between October 1 two years prior to the measurement year (2016) and December 31 of the measurement year (2018).

Cervical Cancer Screening (CCS)

Methodology: HEDIS®

Measure Description: The percentage of Women 21–64 years of age who were screened for cervical cancer using either of the following criteria:

- Women age 21–64 who had cervical cytology performed every 3 years.
- Women age 30–64 who had cervical cytology/human papillomavirus (HPV) co-testing performed every 5 years.
- The eligible population in the measure meets all of the following criteria:
    1. Women 24-64 years as of December 31 of the measurement year (2018).
    2. Continuous enrollment during the measurement year (2018) with no more than one gap in enrollment of up to 45 days.

CODES TO IDENTIFY CERVICAL CYTOLOGY:			
Service	**Code Type**	**Code**	**Code Description**
Cervical Cancer Screening	CPT	88141	Cytopathology Cervical Or Vaginal (any Reporting System) Requiring Interpretation By Physician (List separately In addition to code for technical service.)
Cervical Cancer Screening	CPT	88142	Cytopathology Cervical Or Vaginal (any Reporting System) Collected In Preservative Fluid Automated Thin Layer Preparation Manual screening Under Physician Supervision

CODES TO IDENTIFY CERVICAL CYTOLOGY:			
Service	**Code Type**	**Code**	**Code Description**
Cervical Cancer Screening	CPT	88143	Cytopathology Cervical Or Vaginal (any Reporting System) Collec Ted In Preservative Fluid Automated Thin Layer Preparation; manual screening Under Physician Supervision: With manual screening and rescreening Under Physician Supervision
Cervical Cancer Screening	CPT	88147	Cytopathology Smears Cervical Or Vaginal Screening By Automated System Under Physician Supervision
Cervical Cancer Screening	CPT	88148	Cytopathology Smears Cervical Or Vaginal Screening By Automated System With Manual Rescreening Under Physician Supervision
Cervical Cancer Screening	CPT	88150	Cytopathology Slides Cervical Or Vaginal Manual Screening Under Physician Supervision
Cervical Cancer Screening	CPT	88152	Cytopathology Slides Cervical Or Vaginal With Manual Screening And Computer-assisted Rescreening Under Physician Supervision
Cervical Cancer Screening	CPT	88153	Cytopathology Slides Cervical Or Vaginal With Manual Screening And Rescreening Under Physician Supervision
Cervical Cancer Screening	CPT	88154	Cytopathology Slides Cervical Or Vaginal With Manual Screening And Computer-assisted Rescreening Using Cell Selection And Review Under Physician Supervision
Cervical Cancer Screening	CPT	88164	Cytopathology Slides Cervical Or Vaginal (the Bethesda System) Manual Screening Under Physician Supervision
Cervical Cancer Screening	CPT	88165	Cytopathology Slides Cervical Or Vaginal (the Bethesda System) With Manual Screening And Rescreening Under Physician Supervision
Cervical Cancer Screening	CPT	88166	Cytopathology Slides Cervical Or Vaginal (the Bethesda System) With Manual Screening And Computer-assisted Rescreening Under Physician Supervision
Cervical Cancer Screening	CPT	88167	Cytopathology Slides Cervical Or Vaginal (the Bethesda System) With Manual Screening And Computer-assisted Rescreening Using cell selection and review Under Physician Supervision
Cervical Cancer Screening	CPT	88174	Cytopathology Cervical Or Vaginal (any Reporting System) Collected In Preservative Fluid Automated Thin Layer Preparation
Cervical Cancer Screening	CPT	88175	Cytopathology Cervical Or Vaginal (any Reporting System) Collected In Preservative Fluid Screening Automated By System
Cervical Cancer Screening	HCPCS	G0123	Screening Cytopathology, Cervical Or Vaginal (any Reporting System), Collected In Preservative Fluid, Automated Thin Layer Preparation, Screening By Cytotechnologist Under Physician Supervision (g0123)
Cervical Cancer Screening	HCPCS	G0124	Screening Cytopathology, Cervical Or Vaginal (any Reporting System), Collected In Preservative Fluid, Automated Thin Layer Preparation, Requiring Interpretation By Physician (g0124)

CODES TO IDENTIFY CERVICAL CYTOLOGY:			
Service	**Code Type**	**Code**	**Code Description**
Cervical Cancer Screening	HCPCS	G0141	Screening Cytopathology Smears, Cervical Or Vaginal, Performed By Automated System, With Manual Rescreening, Requiring Interpretation By Physician (g0141)
Cervical Cancer Screening	HCPCS	G0143	Screening Cytopathology, Cervical Or Vaginal (any Reporting System), Collected In Preservative Fluid, Automated Thin Layer Preparation, With Manual Screening And Rescreening By Cytotechnologist Under Physician Supervision (g0143)
Cervical Cancer Screening	HCPCS	G0144	Screening Cytopathology, Cervical Or Vaginal (any Reporting System), Collected In Preservative Fluid, Automated Thin Layer Preparation, With Screening By Automated System, Under Physician Supervision (g0144)
Cervical Cancer Screening	HCPCS	G0145	Screening Cytopathology, Cervical Or Vaginal (any Reporting System), Collected In Preservative Fluid, Automated Thin Layer Preparation, With Screening By Automated System And Manual Rescreening Under Physician Supervision (g0145)
Cervical Cancer Screening	HCPCS	G0147	Screening Cytopathology Smears, Cervical Or Vaginal, Performed By Automated System Under Physician Supervision (g0147)
Cervical Cancer Screening	HCPCS	G0148	Screening Cytopathology Smears, Cervical Or Vaginal, Performed By Automated System With Manual Rescreening (g0148)
Cervical Cancer Screening	HCPCS	P3000	Screening Papanicolaou Smear, Cervical Or Vaginal, Up To Three Smears, By Technician Under Physician Supervision (p3000)
Cervical Cancer Screening	HCPCS	P3001	Screening Papanicolaou Smear, Cervical Or Vaginal, Up To Three Smears, Requiring Interpretation By Physician (p3001)
Cervical Cancer Screening	HCPCS	Q0091	Screening Papanicolaou Smear; Obtaining, Preparing And Conveyance Of Cervical Or Vaginal Smear To Laboratory (q0091)
Cervical Cancer Screening	LOINC	10524-7	Microscopic Observation [identifier] In Cervix By Cyto Stain
Cervical Cancer Screening	LOINC	18500-9	Microscopic Observation [identifier] In Cervix By Cyto Stain Thinprep
Cervical Cancer Screening	LOINC	19762-4	General Categories [interpretation] Of Cervical Or Vaginal Smear Or Scraping By Cyto Stain

- Members who meet any of the following criteria are excluded:
    1. Members who have had a hysterectomy with no residual cervix, cervical agenesis or acquired absence of cervix any time during their history through December 31, 2018 may be excluded.

       To exclude Members who meet the exclusion criteria, please complete the Member Historical Data Form and fax to IEHP's Quality Informatics Team at: 909-477-8568.

       A copy of the Historical Data Form is available in Appendix 3.
    2. Members in hospice are excluded.

Denominator: Women 24-64 years of age who met the criteria for eligible population.

Numerator: Women in the denominator who received a timely screen for cervical cancer.

Timeliness of Prenatal Care (PPC)

Methodology: HEDIS®

Measure Description: The percentage of deliveries of live births on or between November 6, 2017 and November 5, 2018 that received a prenatal care visit as a Member of the organization in the first trimester, on the enrollment start date or within 42 days of enrollment in the organization.

- The eligible population in this measure meets all of the following criteria:
    1. Continuous enrollment 43 days prior to delivery through 56 days after delivery with no allowable gap.
    2. Members who delivered a live birth on or between November 6 of the year prior to the measurement year (2017) and November 5 of the measurement year (2018). This includes women who delivered in any setting. Women who had two separate deliveries (different dates of service) between November 6 of the year prior to the measurement year (2017) and November 5 of the measurement year (2018) count twice. Women who had multiple live births during one pregnancy count once.

CODES TO IDENTIFY STAND ALONE PRENATAL VISITS:			
Service	**Code Type**	**Code**	**Code Description**

Prenatal Visit	HCPCS	H1001	Prenatal Care, At-risk Enhanced Service; Antepartum Management
Prenatal Visit	HCPCS	H1002	Prenatal Care, At Risk Enhanced Service; Care Coordination
Prenatal Visit	HCPCS	H1003	Prenatal Care, At-risk Enhanced Service; Education
Prenatal Visit	HCPCS	H1004	Prenatal Care, At-risk Enhanced Service; Follow-up Home Visit
Prenatal Visit	HCPCS	Z1032	Initial Antepartum Office Visit
Prenatal Visit	HCPCS	Z1034	Antepartum Follow-Up Visit

Prenatal care visit to an OB/GYN or other prenatal care practitioner or PCP. For visits to a PCP, a diagnosis of pregnancy must be present. Documentation in the medical record must include a note indicating the date when the prenatal care visit occurred, and evidence of one of the following.

- A basic physical obstetrical examination that includes auscultation for fetal heart tone, or pelvic exam with obstetric observations, or measurement of fundus height (a standardized prenatal flow sheet may be used).

- Evidence that a prenatal care procedure was performed, such as:
  - Screening test in the form of an obstetric panel (must include all of the following: hematocrit, differential WBC count, platelet count, hepatitis B surface antigen, rubella antibody, syphilis test, RBC antibody screen, Rh and ABO blood typing), OR
  - TORCH antibody panel alone, OR
  - A rubella antibody test/titer with an Rh incompatibility (ABO/Rh) blood typing, OR
  - Echography of a pregnant uterus.
- Documentation of LMP or EDD in conjunction with either of the following.
  - Prenatal risk assessment and counseling/education.
  - Complete obstetrical history.
- Members in hospice are excluded.

Denominator: Members who delivered a live birth on or between November 6 of the year prior to the measurement year (2017) and November 5 of the measurement year (2018).

Numerator: Members in the denominator who had a prenatal care visit as a member of the organization in the first trimester, on the enrollment start date or within 42 days of enrollment in the organization.

Postpartum Care (PPC)

Methodology: HEDIS®

Measure Description: The percentage of deliveries of live births on or between November 6, 2017 and November 5, 2018 that had a postpartum visit on or between 21 and 56 days after delivery.

- The eligible population in this measure meets all of the following criteria:
  1. Continuous enrollment 43 days prior to delivery through 56 days after delivery with no allowable gap.
  2. Members who delivered a live birth on or between November 6 of the year prior to the measurement year (2017) and November 5 of the measurement year (2018). This includes women who delivered in any setting. Women who had two separate deliveries (different dates of service) between November 6 of the year prior to the measurement year (2017) and November 5 of the measurement year (2018) count twice. Women who had multiple live births during one pregnancy count once.

CODES TO IDENTIFY POSTPARTUM CARE:			
Service	**Code Type**	**Code**	**Code Description**

Postpartum Care	ICD10CM	Z01.419	[z01.419] Encounter For Gynecological Examination (general) (routine) Without Abnormal Findings
Postpartum Care	ICD10CM	Z01.42	[z01.42] Encounter For Cervical Smear To Confirm Findings Of Recent Normal Smear Following Initial Abnormal Smear
Postpartum Care	ICD10CM	Z30.430	[z30.430] Encounter For Insertion Of Intrauterine Contraceptive Device
Postpartum Care	ICD10CM	Z39.1	[z39.1] Encounter For Care And Examination Of Lactating Mother
Postpartum Care	ICD10CM	Z39.2	[z39.2] Encounter For Routine Postpartum Follow-up
Postpartum Care	HCPCS	Z1038	Postpartum Follow-Up Office Visit

- Members in hospice are excluded.

Denominator: Members who delivered a live birth on or between November 6 of the year prior to the measurement year (2017) and November 5 of the measurement year (2018).

Numerator: Members in the denominator who had a postpartum visit on or between 21 and 56 days after delivery.

Population: Child

Childhood Immunizations (CIS) – Combo 10

Methodology: HEDIS®

Measure Description: The percentage of children 2 years of age who had four diphtheria, tetanus and acellular pertussis (DTaP); three polio (IPV); one measles, mumps and rubella (MMR); three haemophilus influenza type B (HiB); three hepatitis B (HepB), one chicken pox (VZV); four pneumococcal conjugate (PCV); one hepatitis A (HepA); two or three rotavirus (RV); and two influenza (flu) vaccines by their second birthday. The measure calculates a rate for each vaccine and one combination rate.

- Combo 10 includes the timely completion of the following antigens:
  - DTaP; IPV; MMR; HiB; HepB; VZV; PCV; HepA; Rotavirus; Flu
- The eligible population in this measure meets all of the following criteria:
  1. Children who turn 2 years of age during the measurement year (2018).
  2. Continuous enrollment 12 months prior to the child's second birthday with no more than one gap in enrollment of up to 45 days during the 12 months prior to the child's second birthday.

CHILDHOOD IMMUNIZATION CODE SET:			
Antigen	**Code Type**	**Code**	**Code Description**
DTaP	CPT	90698	Diphtheria Tetanus Toxoids And Acellular Pertussis Vaccine And Hemophilus Influenza B Vaccine And Activated Poliovirus Vaccine, (DTaP-IPV/Hib), For Intramuscular Use
DTaP	CPT	90700	Diphtheria Tetanus Toxoids And Acellular Pertussis Vaccine (dta P) For Intramuscular Use

Flu	CPT	90673	Influenza Virus Vaccine Trivalent Derived From Recombinant Dna (r Iv3) Hemagglutinin (ha) Protein Only Preservative And Antibiotic
Flu	CPT	90685	Influenza Virus Vaccine Quadrivalent (II4V) Split Virus preservative free, 0.25 ml dosage, For Intramuscular Use
Flu	CPT	90686	Influenza Virus Vaccine Quadrivalent (II4V) Split Virus preservative free, 0.5 ml dosage, For Intramuscular Use
Flu	CPT	90687	Influenza Virus Vaccine Quadrivalent (II4V) Split Virus, 0.25 ml dosage, For Intramuscular Use
Flu	CPT	90688	Influenza Virus Vaccine Quadrivalent (II4V) Split Virus, 0.5 ml dosage, For Intramuscular Use
Flu	HCPCS	G0008	Administration Of Influenza Virus Vaccine (g0008)

- Members who meet any of the following criteria are excluded:
    1. Members in hospice are excluded.
    2. Children who had a contraindication for a specific vaccine are excluded from the denominator for all antigen rates and the combination rates.

Denominator: Children 2 years of age in the eligible population.

Numerator: Members in denominator who show timely completion of all antigens in combo10.

Immunizations for Adolescents (IMA) – Combo 2

Methodology: HEDIS®

Measure Description: The percentage of adolescents 13 years of age who had one dose of meningococcal conjugate; vaccine, one tetanus, diphtheria toxoids and acellular pertussis (Tdap); vaccine and two or three doses of the human papillomavirus (HPV) vaccine on or before their 13th birthday. The measure calculates a rate for each vaccine and a combination rate.

- At least one dose of meningococcal conjugate vaccine on or between the Member's 11th and 13th birthdays.
- At least one tetanus, diphtheria toxoids and acellular pertussis (Tdap) vaccine on or between the Member's 10th and 13th birthdays.
- At least two HPV vaccines, with different dates of service on or between the Member's 9th and 13th birthdays.
  - There must be at least 146 days between the first and second dose of the HPV vaccine. For example, if the service date for the first vaccine was March 1, then the service date for the second vaccine must be after July 25.

    OR

    At least three HPV vaccines, with different dates of service on or between the Member's 9th and 13th birthdays.
- The eligible population in this measure meets all of the following criteria:
  1. Adolescents who turn 13 years of age during the measurement year (2018).
  2. Continuous enrollment 12 months prior to the member's 13th birthday with no more than one gap in enrollment of up to 45 days during the 12 months prior to the 13th birthday.

CODES TO IDENTIFY MENINGOCOCAL:			
Antigen	**Code Type**	**Code**	**Code Description**
Meningococcal conjugate	CPT	90734	Meningococcal Conjugate Vaccine Serogroups A, C, Y and W-135, quadrivalent (MCV4 or MenACWY), For Intramuscular Use

CODES TO IDENTIFY TDAP:			
Antigen	**Code Type**	**Code**	**Code Description**
Tdap	CPT	90715	Tetanus Diphtheria Toxoids And Acellular Pertussis Vaccine (Tdap) When Administered To Individuals 7 Years Or Older For Intramuscular Use

CODES TO IDENTIFY HPV:			
Antigen	**Code Type**	**Code**	**Code Description**
HPV	CPT	90649	Human Papilloma Virus (hpv) Vaccine Types 6 11 16 18 Quadrivalent (4vHPV), 2 or 3 Dose Schedule, For Intramuscular Use
HPV	CPT	90650	Human Papilloma Virus (hpv) Vaccine Types 16, 18 bivalent (2vHPV) 2 or 3 Dose Schedule, For Intramuscular Use
HPV	CPT	90651	Human Papilloma Virus Vaccine 6 11 16 18 31 33 45 52 58, nonavalent (9vHPV) 2 or 3 Dose Schedule, For Intramuscular Use

- Members who meet any of the following criteria are excluded:
    1. Members in hospice are excluded.
    2. Adolescents who had a contraindication for a specific vaccine are excluded from the denominator for all antigen rates and the combination rates.

Denominator: Adolescents 13 years of age who meet all the criteria for eligible population.

Numerator: Members in the denominator who had one dose of meningococcal conjugate vaccine, one tetanus, diphtheria toxoids and acellular pertussis (Tdap) vaccine, and have completed the human papillomavirus (HPV) vaccine series by their 13th birthday during the measurement year (2018).

Well-Child 3-6 Years of life (W34)

Methodology: HEDIS®

Measure Description: The percentage of Members 3–6 years of age who had one or more well-child visits with a PCP during the measurement year (2018).

- The eligible population in this measure meets all of the following criteria:
  1. Age 3-6 years as of December 31 of the measurement year (2018).
  2. Continuous enrollment in the measurement year (2018) with no more than one gap in enrollment of up to 45 days.

CODES TO IDENTIFY WELL-CHILD: (*NOTE: These codes must be provided by a Primary Care Provider in an office setting.*)			
Service	**Code Type**	**Code**	**Code Description**
Well-Child 3-6 Years of Life	CPT	99382	Initial comprehensive preventive medicine evaluation and management of an individual including an age and gender appropriate history, examination, counseling/anticipatory guidance/risk factor reduction interventions, and the ordering of laboratory/diagnostic procedures, new patient: early childhood (age 1 through 4 years)
Well-Child 3-6 Years of Life	CPT	99383	Initial comprehensive preventive medicine evaluation and management of an individual including an age and gender appropriate history, examination, counseling/anticipatory guidance/risk factor reduction interventions, and the ordering of laboratory/diagnostic procedures, new patient: late childhood (age 5 through 11 years)
Well-Child 3-6 Years of Life	CPT	99392	Periodic comprehensive preventive medicine reevaluation and management of an individual including an age and gender appropriate history, examination, counseling/anticipatory guidance/risk factor reduction interventions, and the ordering of laboratory/diagnostic procedures, established patient; early childhood (age 1 through 4 years)
Well-Child 3-6 Years of Life	CPT	99393	Periodic comprehensive preventive medicine reevaluation and management of an individual including an age and gender appropriate history, examination, counseling/anticipatory guidance/risk factor reduction interventions, and the ordering of laboratory/diagnostic procedures, established patient; late childhood (age 5 through 11 years)

Well-Child 3-6 Years of Life	HCPCS	G0439	Annual Wellness Visit, Includes A Personalized Prevention Plan Of Service (pps), Subsequent Visit (g0439)
Well-Child 3-6 Years of Life	ICD10CM	Z00.121	Encounter For Routine Child Health Examination With Abnormal Findings
Well-Child 3-6 Years of Life	ICD10CM	Z00.129	Encounter For Routine Child Health Examination Without Abnormal Findings
Well-Child 3-6 Years of Life	ICD10CM	Z00.5	Encounter For Examination Of Potential Donor Of Organ And Tissue

CODES TO IDENTIFY WELL-CHILD: (*NOTE: These codes must be provided by a Primary Care Provider in an office setting.*)			
Service	**Code Type**	**Code**	**Code Description**
Well-Child 3-6 Years of Life	ICD10CM	Z00.8	Encounter For Other General Examination
Well-Child 3-6 Years of Life	ICD10CM	Z02.0	Encounter For Examination For Admission To Educational Institution
Well-Child 3-6 Years of Life	ICD10CM	Z02.1	Encounter For Pre-employment Examination
Well-Child 3-6 Years of Life	ICD10CM	Z02.2	Encounter For Examination For Admission To Residential Institution
Well-Child 3-6 Years of Life	ICD10CM	Z02.5	Encounter For Examination For Participation In Sport
Well-Child 3-6 Years of Life	ICD10CM	Z02.6	Encounter For Examination For Insurance Purposes
Well-Child 3-6 Years of Life	ICD10CM	Z02.71	Encounter For Disability Determination
Well-Child 3-6 Years of Life	ICD10CM	Z02.79	Encounter For Issue Of Other Medical Certificate
Well-Child 3-6 Years of Life	ICD10CM	Z02.81	Encounter For Paternity Testing
Well-Child 3-6 Years of Life	ICD10CM	Z02.82	Encounter For Adoption Services
Well-Child 3-6 Years of Life	ICD10CM	Z02.83	Encounter For Blood-alcohol And Blood-drug Test
Well-Child 3-6 Years of Life	ICD10CM	Z02.89	Encounter For Other Administrative Examinations
Well-Child 3-6 Years of Life	ICD10CM	Z02.9	Encounter For Administrative Examinations, Unspecified

- Members in hospice are excluded.

Denominator: Members 3-6 years of age who meet all the criteria for eligible population.

Numerator: Members in the denominator who had at least one well-child visit with a PCP during the measurement year (2018).

The Well-Child visit must occur with a PCP, but the PCP does not have to be the practitioner assigned to the child.

Weight Assessment and Counseling for Nutrition and Physical Activity for Children and Adolescents (WCC)

Methodology: HEDIS®

Measure Description: The percentage of Members 3–17 years of age who had an outpatient visit with a PCP or OB/GYN and who had evidence of the following during the measurement year (2018). Report each of the three indicators below.

- BMI percentile documentation*
- Counseling for nutrition
- Counseling for physical activity
- The eligible population in this measure meets all of the following criteria:
    1. Members who are 3-17 years of age as of December 31 of the measurement year (2018).
    2. Continuous enrollment in the measurement year (2018) with no more than one gap up to 45 days.
    3. An outpatient visit with a PCP or an OB/GYN during the measurement year (2018).

* Because BMI norms for youth vary with age and gender, this measure evaluates whether BMI percentile is assessed rather than an absolute BMI value.

CODES TO IDENTIFY BMI PERCENTILE:		
Code	**Code Type**	**Description**
Z68.51	ICD10	Body Mass Index (BMI) Pediatric, Less Than 5th Percentile For Age
Z68.52	ICD10	Body Mass Index (BMI) Pediatric, 5th Percentile To Less Than 85th Percentile For Age
Z68.53	ICD10	Body Mass Index (BMI) Pediatric, 85th Percentile To Less Than 95th Percentile For Age
Z68.54	ICD10	Body Mass Index (BMI) Pediatric, Greater Than Or Equal To 95th Percentile For Age

CODES TO IDENTIFY COUNSELING FOR PHYSICAL ACTIVITY:		
Code	**Code Type**	**Description**
G0447	HCPCS	Face-to-face Behavioral Counseling For Obesity, 15 Minutes
S9451	HCPCS	Exercise Classes, Non-Physician Provider, Per Session
Z02.5	ICD10	Encounter For Examination For Participation In Sport
Z71.82	ICD10	Exercise Counseling

CODES TO IDENTIFY COUNSELING FOR NUTRITION:		
Code	**Code Type**	**Description**
97802	CPT	Medical Nutrition Therapy Initial Assessment And Intervention Individual Face-to-face With The Patient Each 15 Minutes
97803	CPT	Medical Nutrition Therapy Re-assessment And Intervention Individual Face-to-face With The Patient Each 15 Minutes
97804	CPT	Medical Nutrition Therapy Group (2 Or More Individual(s)) Each 30 Minutes
G0270	HCPCS	Medical Nutrition Therapy; Reassessment And Subsequent Intervention(s) Following Second Referral In Same Year For Change In Diagnosis, Medical Condition Or Treatment Regimen (including Additional Hours Needed For Renal Disease), Individual, Face To Face
G0271	HCPCS	Medical Nutrition Therapy, Reassessment And Subsequent Intervention(s) Following Second Referral In Same Year For Change In Diagnosis, Medical Condition, Or Treatment Regimen (including Additional Hours Needed For Renal Disease), Group (2 Or More Individuals)
G0447	HCPCS	Face-to-face Behavioral Counseling For Obesity, 15 Minutes (G0447)
S9449	HCPCS	Weight Management Classes, Non-Physician Provider, Per Session (S9449)
S9452	HCPCS	Nutrition Classes, Non-Physician Provider, Per Session (S9452)
S9470	HCPCS	Nutritional Counseling, Dietitian Visit (S9470)
Z71.3	ICD10	Dietary Counseling And Surveillance

Members who meet any of the following criteria are excluded:

1. Members in hospice are excluded.
2. Female Members who have a diagnosis of pregnancy during the measurement year (2018) are excluded. A diagnosis of pregnancy will be determined using claims and encounter data only.

Denominator: Members 3-17 years of age who meet all the criteria for eligible population.

Numerator: Members in the denominator who had evidence of BMI, counseling of nutrition or physical activity during the measurement year (2018).

Population: All

Initial Health Assessment (IHA)

Methodology: IEHP-Defined Compliance Metric

Measure Description: The IHA is a comprehensive assessment that is completed during the Member's initial encounter with a PCP, appropriate medical specialist, or Non-Physician medical Provider and must be documented in the Member's medical record. The IHA enables the Member's PCP to assess and manage the acute, chronic and preventive health needs of the Member.

IEHP provides PCPs a monthly detailed Member roster on the IEHP Secure Provider Portal for all newly enrolled IEHP Members who are due for an IHA after 120 days of enrollment.

- The eligible population is newly assigned Members with an IEHP effective enrollment date of January 1, 2018 through December 31, 2018. The IHA must be provided within 120 days of enrollment (e.g., Member enrolled in December 2018 must be seen by April 2019 and PCP must submit encounter by May 2019)
- IHA visits completed during the 11 months prior to enrollment with IEHP count towards numerator compliance.

Concurrent Use of Opioids and Benzodiazepines

Methodology: IEHP-Defined Compliance Metric

Measure Description: The Concurrent Use of Opioids and Benzodiazepines measure specification is developed and maintained by the Pharmacy Quality Alliance (PQA). This measure examines the percentage of individuals 18 years and older with concurrent use of prescription opioids and benzodiazepines. The denominator includes individuals 18 years and older by the first day of the measurement year with two or more prescription claims for opioids filled on two or more separate days, for which the sum of the days supply is 15 or more days during the measurement period. The numerator includes individuals from the denominator with two or more prescription claims for benzodiazepines filled on two or more separate days, and concurrent use of opioids and benzodiazepines for 30 or more cumulative days.

Exclusion: Patients in hospice care and those with a cancer diagnosis are excluded.

Access to Care Needed Right Away

Methodology: Monthly Member Satisfaction Survey.

Measure Description: In the last six months, when you needed care right away, how often did you get care as soon as you needed it?

- Valid response: never, sometimes, usually, always
- Target response: usually, always

Measure Support: To help identify opportunities to improve customer service, IEHP conducts a monthly Member Satisfaction Survey between June-December annually. Member survey responses are analyzed and shared at the PCP level.

Coordination of Care

Methodology: Monthly Member Satisfaction Survey

Measure Description: In the last six months, how often did your Personal Doctor seem informed and up-to-date about the care you got from these doctors or other health providers?

- Valid response: never, sometimes, usually, always
- Target response: usually, always

Measure Support: To help identify opportunities to improve customer service, IEHP conducts a monthly Member Satisfaction Survey between June-December annually. Member Survey responses are analyzed and shared at the PCP level.

Rating of Access to Routine Care

Methodology: Monthly Member Satisfaction Survey

Measure Description: In the last six months, how often did you get an appointment for a check-up or routine care at a Doctor's office or clinic as soon as you needed it?

- Valid response: never, sometimes, usually, always
- Target response: usually, always

Measure Support: To help identify opportunities to improve customer service, IEHP conducts a monthly Member Satisfaction Survey between June-December annually. Member Survey responses are analyzed and shared at the IPA level.

INLAND EMPIRE HEALTH PLAN

HISTORICAL DATA FORM

The Historical Data form is for submissions of visits, procedures or services to close quality gaps in care as reflected on the Preventative Care Rosters that cannot be submitted via claims or encounters (e.g. services received prior to IEHP Membership, historical surgical procedures, etc.). **Any form submitted without appropriate proof of service documentation or any form that doesn't include Member name, DOB and date of service will NOT be processed.**

Results from LabCorp, Quest, BioData, RadNet, ARMC, RUHS, and Loma Linda **do not require submission** as IEHP receives this information directly.

Type of Historical Data:

- ☐ **PAP ONLY**
- ☐ **PAP AND HPV [co-testing]**
- ☐ **History of Total/Complete Hysterectomy [NO residual cervix]**
- ☐ **Mammogram**
- ☐ **History of Mastectomy**
- ☐ **Dilated Retinal Exam with Results**
- ☐ **Group A Streptococcus (Strep) Test – Throat**
- ☐ **HbA1c Results (for in-office Point of Care Testing)**
- ☐ **Other:**_____

For Immunizations - Please submit through CAIR2 website: https://cair.cdph.ca.gov

IEHP MEDI-CAL ADULT MEMBER SATISFACTION SURVEY 2017

Instructions: Answer each question by marking the box to the left of your answer.

You are sometimes told to skip over some questions in this survey. When this happens you will see an arrow with a note that tells you what question to answer next, like this: ☒ Yes ➔ **If Yes, go to #1 on page 1**
☐ No

Your Personal Doctor

1. **A personal doctor is the one you would see if you need a check-up, want advice about a health problem, or get sick or hurt. Do you have a personal doctor?**
   - ☐1 Yes
   - ☐2 No ➔ **If No, go to Question 14**

2. **In the last 6 months, how often did your personal doctor explain things in a way that was easy to understand?**
   - ☐1 Never
   - ☐2 Sometimes
   - ☐3 Usually
   - ☐4 Always

3. **In the last 6 months, how often did your personal doctor listen carefully to you?**
   - ☐1 Never
   - ☐2 Sometimes
   - ☐3 Usually
   - ☐4 Always

4. **In the last 6 months, how often did your personal doctor show respect for what you had to say?**
   - ☐1 Never
   - ☐2 Sometimes
   - ☐3 Usually
   - ☐4 Always

5. **In the last 6 months, how often did your personal doctor spend enough time with you?**
   - ☐1 Never
   - ☐2 Sometimes
   - ☐3 Usually
   - ☐4 Always

6. **In the last 6 months, how often did you and your personal doctor talk about all the prescribed medicines you take?**
   - ☐1 Never
   - ☐2 Sometimes
   - ☐3 Usually
   - ☐4 Always

7. **In the last 6 months, when you had a scheduled visit with your doctor, did he or she have your health records or other facts about your care?**
   - ☐1 Never
   - ☐2 Sometimes
   - ☐3 Usually
   - ☐4 Always

8. **In the last 6 months, did your doctor order a blood test, x-ray or other test for you?**
   - ☐1 Yes
   - ☐2 No ➔ **If No, go to Question 10**

9. **In the last 6 months, when your doctor ordered a blood test, x-ray or other test for you, how often did someone from your doctor's office give you those results?**
   - ☐1 Never
   - ☐2 Sometimes
   - ☐3 Usually
   - ☐4 Always

10. **Would you send a friend to see your doctor?**
    - ☐1 Yes
    - ☐2 No

11. **Using any number from 0 to 10, where 0 is the worst personal doctor possible and 10 is the best personal doctor possible, what number would you use to rate your "personal doctor"?**
    - ☐ 0 Worst personal doctor possible
    - ☐ 1
    - ☐ 2
    - ☐ 3
    - ☐ 4
    - ☐ 5
    - ☐ 6
    - ☐ 7
    - ☐ 8
    - ☐ 9
    - ☐ 10 Best personal doctor possible

Clerks and Receptionists at your Personal Doctor's Office

12. In the last 6 months, how often were clerks and receptionists at your personal doctor's office as helpful as you thought they should be?
    - 1 Never
    - 2 Sometimes
    - 3 Usually
    - 4 Always

13. In the last 6 months, how often did clerks and receptionists at your personal doctor's office treat you with courtesy and respect?
    - 1 Never
    - 2 Sometimes
    - 3 Usually
    - 4 Always

Your Access to Care in the Last 6 Months

These questions ask about your own health care. Do not include care you got when you stayed overnight in a hospital. Do not include the times you went for dental care visits.

14. In the last 6 months, did you have an illness, injury, or condition that needed care right away in a clinic, emergency room, or doctor's office?
    - 1 Yes
    - 2 No ➔ If No, go to Question 16

15. In the last 6 months, when you needed care right away, how often did you get care as soon as you needed?
    - 1 Never
    - 2 Sometimes
    - 3 Usually
    - 4 Always

16. In the last 6 months, did you make any appointments for a check-up or routine care at a doctor's office or clinic?
    - 1 Yes
    - 2 No ➔ If No, go to Question 18

17. In the last 6 months, how often did you get an appointment for a check-up or routine care at a doctor's office or clinic as soon as you needed?
    - 1 Never
    - 2 Sometimes
    - 3 Usually
    - 4 Always

18. In the last 6 months, did you need care after normal office hours?
    - 1 Yes
    - 2 No ➔ If No, go to Question 21

19. In the last 6 months, how often was it easy to get the after-hours care you thought you needed?
    - 1 Never
    - 2 Sometimes
    - 3 Usually
    - 4 Always

20. In the last 6 months, when you needed after-hours care, what did you do?
    - 1 Called IEHP Nurse Advice Line
    - 2 Called my personal doctor's office
    - 3 Went to the Urgent Care
    - 4 Went to the Emergency Room
    - 5 Did not get care
    - 6 Other

21. In the last 6 months, did you take any prescribed medicine?
    - 1 Yes
    - 2 No ➔ If No, go to Question 24

22. In the last 6 months, how often was it easy to get your prescribed medicine?
    - 1 Never
    - 2 Sometimes
    - 3 Usually
    - 4 Always

23. In the last 6 months, how often were your prescriptions not ready for you at the pharmacy due to an issue with IEHP's Prior Authorization process?
    - 1 Never
    - 2 Sometimes
    - 3 Usually
    - 4 Always
    - 5 Don't know

24. In the last 6 months, did you try to get information or help about prescriptions from IEHP's customer service?
    - 1 Yes
    - 2 No ➔ If No, go to Question 27

25. In the last 6 months, how often did IEHP's customer service give you the information or help you needed about prescription drugs?
    - 1 Never
    - 2 Sometimes
    - 3 Usually
    - 4 Always

26. In the last 6 months, how often did IEHP's customer service staff treat you with courtesy and respect when you tried to get information or help about prescription drugs?
    - 1 Never
    - 2 Sometimes
    - 3 Usually
    - 4 Always

27. In the last 6 months, did you get care from a doctor or other health provider besides your personal doctor?
    - 1 Yes
    - 2 No ➔ If No, go to Question 29

28. In the last 6 months, how often did your personal doctor seem informed and up-to-date about the care you got from these doctors or other health providers?
    - 1 Never
    - 2 Sometimes
    - 3 Usually
    - 4 Always

29. Using any number from 0 to 10, where 0 is the worst health care possible and 10 is the best health care possible, what number would you use to rate all your health care in the last 6 months??
    - 0 Worst health care possible
    - 1
    - 2
    - 3
    - 4
    - 5
    - 6
    - 7
    - 8
    - 9
    - 10 Best health care possible

Your Health Plan: Inland Empire Health Plan (IEHP)

The next questions ask about your experience with your health plan.

30. In the last 6 months, did you get information or help from IEHP's customer service?
    - 1 Yes
    - 2 No ➔ If No, go to Question 33

31. In the last 6 months, how often did IEHP's customer service give you the information or help you needed?
    - 1 Never
    - 2 Sometimes
    - 3 Usually
    - 4 Always

32. In the last 6 months, how often did IEHP's customer service staff treat you with courtesy and respect?
    - 1 Never
    - 2 Sometimes
    - 3 Usually
    - 4 Always

33. Using any number from 0 to 10, where 0 is the worst health plan possible and 10 is the best health plan possible, what number would you use to rate your health plan?
    - 0 Worst health plan possible
    - 1
    - 2
    - 3
    - 4
    - 5
    - 6
    - 7
    - 8
    - 9
    - 10 Best health plan possible

12	Monthly Submission Volume Meeting IEHP Target Adequacy Rate	5
13	Monthly Submissions Accepted with <1% Error Rate	5
14	Tracking of Capitated Provider-Level Encounters	5
15	Use of Supplemental Data to improve data capture	5
16	Supplemental Data shared with IEHP timely and in agreed upon format	5
	Patient Experience Domain	
17	Physician-level Reports and Monitoring of Performance Metrics	5
18	Office Staff and Physician Education Programs to Improve Patient Experience	5
19	Office Staff/ Practitioner Recognition Programs for High Performers	5
OVERALL PROGRAM SCORE		**100**

APPENDIX 6: *Supplemental Claim File Data Dictionary*

The Claim file contains claims for medical services. It may also contain lab services that do not have an associated result, pharmaceuticals administered in the practitioners office (usually documented by J codes in the CPT Field), and medical encounter data. The Claim file should contain one record per unique claim line.

SUPPLEMENTAL CLAIM FILE DATA DICTIONARY			
Field Name	**Data Type**	**File Order**	**Notes**
MemberKey	Text (14)	1	IEHP Member ID.
ProviderKey	Text (25)	2	This should be the rendering provider's NPI.
ClaimNumber	Text (80)	3	Used to identify the claim source for Primary Source Verification.
DOS	Date	4	The beginning Date of Service for the claim in MM/DD/YYYY format.
DOSThru	Date	5	The ending Date of Service for the claim in MM/DD/YYYY format.
ICD9DxPri	Text (5)	6	ICD-9 diagnosis codes should contain all available digits (including all preceding zeros). Do not include the period that follows the third digit. If no fourth or fifth digit was coded, do not pad the missing spaces. For example, V42.0 should be loaded as V420. With the introduction of ICD-10 code set, IEHP will continue to support the ICD-9 code set as there are historical claims that rely on these codes (for HEDIS we recommend 3-4 years of historical claims data) in order to accurately calculate HEDIS rates.
ICD9DxSec1	Text (5)	7	
ICD9DxSec2	Text (5)	8	
ICD9DxSec3	Text (5)	9	
ICD9DxSec4	Text (5)	10	
ICD9DxSec5	Text (5)	11	
ICD9DxSec6	Text (5)	12	
ICD9DxSec7	Text (5)	13	
ICD9DxSec8	Text (5)	14	
ICD9DxSec9	Text (5)	15	
ICD9DxSec10	Text (5)	16	
ICD10DxPri	Text (7)	17	ICD-10 diagnosis codes should contain all available alphanumeric code. Do not include the decimal. For example, V39.00XS should be coded as V3900XS.
ICD10DxSec1	Text (7)	18	
ICD10DxSec2	Text (7)	19	
ICD10DxSec3	Text (7)	20	
ICD10DxSec4	Text (7)	21	
ICD10DxSec5	Text (7)	22	
ICD10DxSec6	Text (7)	23	
ICD10DxSec7	Text (7)	24	
ICD10DxSec8	Text (7)	25	
ICD10DxSec9	Text (7)	26	
ICD10DxSec10	Text (7)	27	
PCPFlag	Bit	28	Indicator for whether the claim provider serves as a PCP for the health plan. Refers to the provider's contractual relationship to the plan, rather than medical specialty. Valid values are 0 (no), or 1 (yes)
HCFAPOS	Text (2)	29	

SUPPLEMENTAL CLAIM FILE DATA DICTIONARY			
Field Name	**Data Type**	**File Order**	**Notes**
TOB	Text (4)	30	Must be converted to standard 4-digit length by adding leading zeros, if necessary.
UBRevenueCode	Text (4)	31	Must be converted to standard 4-digit length by adding leading zeros, if necessary.
UBOccurCode1	Text (2)	32	
UBOccurCode2	Text (2)	33	
UBOccurCode3	Text (2)	34	
UBOccurCode4	Text (2)	35	
HCPCSPx	Text (5)	36	
HCPCSMOD	Text (2)	37	
CPTPx	Text (5)	38	Level II CPT Codes are supported by HEDIS and should be placed in the same field as other CPT procedure codes.
CPTMOD1	Text (2)	39	
CPTMOD2	Text (2)	40	
ICD9Px1	Text (4)	41	ICD-9 procedure codes should contain all available digits (including all preceding zeros). Do not include the period that follows the third digit. With the introduction of ICD-10 code set, IEHP will continue to support the ICD-9 code set as there are historical claims that rely on these codes (for HEDIS we recommend 3-4 years of historical claims data) in order to accurately calculate HEDIS® rates.
ICD9Px2	Text (4)	42	
ICD9Px3	Text (4)	43	
ICD9Px4	Text (4)	44	
ICD9Px5	Text (4)	45	
ICD9Px6	Text (4)	46	
ICD9Px7	Text (4)	47	
ICD9Px8	Text (4)	48	
ICD9Px9	Text (4)	49	
ICD9Px10	Text (4)	50	
ICD10Px1	Text (7)	51	ICD-10 procedure codes should contain all available alphanumeric code. Do not include the decimal. For example, V39.00XS should be coded as V3900XS.
ICD10Px2	Text (7)	52	
ICD10Px3	Text (7)	53	
ICD10Px4	Text (7)	54	
ICD10Px5	Text (7)	55	
ICD10Px6	Text (7)	56	
ICD10Px7	Text (7)	57	
ICD10Px8	Text (7)	58	
ICD10Px9	Text (7)	59	
ICD10Px10	Text (7)	60	
ProviderSpecialty	Text (15)	61	Use Provider Specialties in the Provider Specialty Crosswalk Tab
POS	Text (2)	62	Place of Service. Also automatically built using a cross-reference. Valid values are: BC (Birthing Center), DN (Day/Night Hospitalization), ER (Emergency Room), IA (Inpatient Acute), IN (Inpatient Non-Acute), LA (Laboratory), OA (Outpatient/ Ambulatory), OC (Office/Clinic), OT (Other), RM (Mail Order Prescription Drugs), RR (Retail Pharmacy).

Supplemental Lab Claim File Data Dictionary

The LabClaim file contains claims for laboratory services and allows lab results to be stored. The LabClaim file should contain one record per unique lab service claim.

SUPPLEMENTAL LAB CLAIM FILE DATA DICTIONARY			
Field Name	**Data Type**	**File Order**	**Notes**
MemberKey	Text (30)	1	
ProviderKey	Text (25)	2	This should be the rendering provider's NPI.
ClaimNumber	Text (80)	3	Used to identify the claim source for Primary Source Verification.
DOS	Date	4	The Date of Service for the claim in MM/DD/YYYY format.
CPTPx	Text (5)	5	Level II CPT Codes are supported by HEDIS and should be placed in the same field as other CPT procedure codes.
LOINC	Text (7)	6	LOINC codes must contain the dash character that precedes the final digit.
HCPCSPx	Text (5)	7	Used for medical services, that comes in through lab claims. Only one HCPCS code per claim line is allowed. If the claim contains multiple HCPCS codes, load them as separate claims.
HCPCSMod	Text (2)	8	
Result	Decimal(28,10)	9	Used to document numeric lab results.
PosNegResult	Bit	10	Used to document positive/negative lab results. Valid values are 0 (negative), or 1 (positive).

APPENDIX 7: *Constructing the IPA Payment Amount per Member Point*

Using the formula below, the Payment Amount per Member Point is calculated as follows:

[Expected Global Quality Performance Score] x [Total Medi-Cal Membership as of 1/2018] =*
Total Member Points

[Total Incentive Dollars Available] / [Total Member Points] =
Payment Amount per Member Point

Final Payment Amount per Member Point Calculation:

EXPECTED GLOBAL QUALITY PERFORMANCE SCORE		TOTAL MEDI-CAL MEMBERSHIP AS OF 1/2018*		MEMBER POINTS
1.88	x	720,776	=	1,355,058.88

PROVIDER	TOTAL INCENTIVE DOLLARS AVAILABLE		MEMBER POINTS		PAYMENT PER MEMBER POINT
IPA	$20,000,000	÷	1,355,058.88	=	$14.76**

**Excludes IEHP Direct, Kaiser, Allied Pacific IPA, Heritage Provider Network and Pomona Valley Medical Group Medi-Cal membership. ** Payment per Member Point is not finalized. Payment Per Member Point will be included in published status reports beginning in the Spring.*

Rates will be shared with IPAs at least quarterly to track progress toward goals.
Initial IPA reports will be available in March 2018.

Quality Improvement

Provider Incentive Program

Welcome to California Health & Wellness

AGENDA

1. Medi-Cal Performance Measures
2. HEDIS Status Report vs. Care in Gap Report
3. Patient Level Compliance Bonus
   - "Critical" Measures
   - "Important" Measures
4. Provider Quality Performance Incentive
   - Star Ratings
5. Notice of Pregnancy Bonus
6. Frequently Asked Questions
7. Things to Remember
8. Quality Incentive Training Series

MEDI-CAL PERFORMANCE MEASURES

california health & wellness

HYBRID MEASURES

- Childhood Immunizations
- Adolescent Immunizations
- Well Child Visits
- Controlling High Blood Pressure
- Cervical Cancer Screening
- Weight Assessment and Counseling for Children/Adolescents *3 indicators
- Prenatal Care
- Postpartum Care
- Comprehensive Diabetes Care *6 indicators

ADMINISTRATIVE MEASURES

- Annual Monitoring for Patients on Persistent Medications *3 indicators
- Children and Adolescents Access to Primary Care Physicians *4 indicators based on age groups
- Medication Management for Asthma *2 indicators
- Avoidance of Antibiotic use for Bronchitis
- Use of imaging studies for low back pain
- Ambulatory Care *2 indicators
- All Cause Readmissions

NOTE: Compliance is based on NCQA HEDIS measure specifications and must be received aa a medical claim with the correct coding or by submission of the medical record with the correct documentation meeting measure compliance guidelines.

WHATS THE DIFFERENCE?

HEDIS STATUS REPORT vs. GAP IN CARE REPORT

california health & wellness

HEDIS STATUS REPORT

- Sent directly to provider location monthly
- Does not include all CHW membership
- Only includes patients/members that are identified for a specific measure
- Eligible for Provider Incentives
  - Patient Level Compliance Bonus
  - Provider Quality Performance Rating
  - Notice of Pregnancy Bonus

GAP IN CARE REPORT

- Located on the Provider Portal
- Includes all CHW membership assignment
- Not all patients/members on the GAP report are eligible for provider incentives

Patient Level Compliance Bonus

california health & wellness

Critical Measures = $75

- Childhood Immunizations
- Well Child Exam for Children Ages 3 to 6
- Controlling High Blood Pressure
- Diabetic Care: HbA1c Test
- Cervical Cancer Screening

Important Measures = $25

- Weight Assessment and Counseling for Children
- Diabetic Care: Eye Exam
- Diabetic Care: Medical Attention to Nephropathy
- Children Access to Primary Care Physicians
- Annual Monitoring for Patients on Persistent Medications
- Adolescent Immunizations

NOTE: Compliance is based on NCQA HEDIS measure specifications and must be received as a medical claim with the correct coding or by submission of the medical record with the correct documentation meeting measure compliance guidelines.

CRITICAL MEASURES

california health & wellness

Childhood Immunizations

- Received combination of vaccines before 2nd Birthday

Well Child Exam for Children ages 3- 6

- Annual "well child" exam - PM-160 Form in California

Prenatal Care

- Initial Prenatal Care visit in 1st Trimester, OR within 42 days of enrollment if enrolled after 1st trimester

Controlling High Blood Pressure

- Patients diagnosed with Hypertension in 1st half of year, need follow-up BP test and value < 140/90

Diabetic Care – Annual HbA1c Blood Test

- Blood test taken anytime in calendar year

Cervical Cancer Screening

- Ages (21-64): Pap test in past 3 years (2013 – 2015)
- Ages (30-64): Pap Test & HPV test in past 5 years (2011-2015)

NOTE: Compliance is based on NCQA HEDIS measure specifications and must be received aa a medical claim with the correct coding or by submission of the medical record with the correct documentation meeting measure compliance guidelines.

PROVIDER QUALITY "STAR" PERFORMANCE INCENTIVE

NOTICE OF PREGNANCY BONUS

Improving Prenatal Care is a critical goal for CAHW and early identification of patients increases the likelihood of success. Providers are asked to complete an NOP – Notice of Pregnancy form for every patient with a new diagnosis of pregnancy. For every new NOP submitted for patients in their first trimester, you will receive a bonus of $75.00

Ongoing Bonus Payout: {Quarterly beginning October 2015}

FREQUENTLY ASKED QUESTIONS

Can I code for immunizations even if I am not charging for them?

- Yes. Coding for immunizations helps identify members that are compliant and those that still need additional vaccines.

Where can I find the Notice of Pregnancy (NOP) form?

- You can find the NOP as well as additional HEDIS information of our Provider Portal located on our website: **www.CAHealthWellness.com**

What if the doctor listed on the report is no longer practicing at this office/location?

- The HSR is reflective of membership assigned at your location . Although the provider is no longer at a particular site, the members are still assigned to that site.

Can I log the data into an Excel Spreadsheet and fax to you?

- Unfortunately no. In adherence to our audit and auditors, we are required to have the specific medical record

Will we get credit for submitting the NOP even if do not practice prenatal care at our facility?

- Yes. We need help identifying women that become pregnant so we can ensure great prenatal care. If a patient is identified as being pregnant, fill out the NOP and send in immediately. The NOP will be paid on a first submitted basis.

What does the "x" stand for on our report?

- The "x" means that the service is still needed for this measure. If the service has been completed already; please fax the medical record documentation to 877-278-9978.

Is this the same incentive program as last year?

- No. This provider incentive program is specific for this year. Each year we will tailor a provider incentive program that continues to improve the health and wellbeing of our members as well as rewarding our stakeholders.

THINGS TO REMEMBER

- 5 critical measures paid at $75 by turning non-compliant into compliant
  - Childhood Immunizations
  - Well Child Visits 3-6 years of age
  - Controlling High Blood Pressure
  - Diabetes Care: HbA1c Tests
  - Cervical Cancer Screening
- 6 important measures paid at $25 by turning non-compliant into compliant
  - Weight Assessment and Counseling for Nutrition and Physical Activity
  - Adolescent Immunizations
  - Diabetes Care: Eye Exam
  - Diabetes Care: Medical Attention for Nephropathy
  - Children and Adolescents Access to Primary Care Physician
  - Annual Monitoring for Patients on Persistent Medications

  ✓ **Bonus Payout: By October 31, 2015** for services in July, August, September

  ✓ **Bonus Payout: By March 31, 2016** for services in October, November, December

- Provider Quality Performance Ratings Payout

  ✓ **Bonus Payout: By March 31, 2016**

- Notice of Pregnancy (NOP) Bonus

  ✓ **Ongoing Bonus Payout starting October 2015**

- Make sure to use the “HEDIS STATUS REPORT” to change your patients from non-compliant to compliant

Please fax clinical documentation to our QI HEDIS Department: (877) 278-9978

2016 Performance Recognition Program

PROVIDER INCENTIVE PROGRAM FOR:

- **BCN Commercial HMO**
- **BCN Advantage℠ HMO-POS**
- **BCBSM Medicare Plus Blue℠ PPO**

CONTENTS

2016 PERFORMANCE RECOGNITION PROGRAM

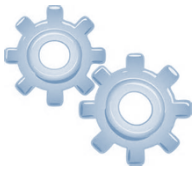
The Provider Performance Recognition Program rewards Blue Care Network Commercial providers and Medicare Advantage providers for both Blue Cross Blue Shield of Michigan and BCN for their role in helping Blue Cross and BCN achieve the objectives of the Healthcare Effectiveness Data and Information Set, or HEDIS®, and the Centers for Medicare & Medicaid Services' star ratings program. These objectives include:

- Better care
- Healthier people and communities
- Affordable care

Each program rewards providers who encourage their patients to get preventive screenings and procedures, such as eye exams and mammograms, and for achieving patient outcomes such as ensuring diabetic members have their blood sugar controlled.

Our philosophy is to use meaningful payments to encourage positive clinical results as well as increase HEDIS outcomes and CMS star ratings.

The components of the program, including the performance measures that are based on HEDIS benchmarks, are described in this booklet. Primary care physicians must have attributed or assigned members to participate in the program.



BLUE CROSS BLUE SHIELD OF MICHIGAN AND BLUE CARE NETWORK
2016 PAYOUT SUMMARY — BCN COMMERCIAL

BCN Commercial HMO payment calculation

Payments for each eligible provider are calculated using the following methodology, regardless of membership level.

1. Quality score: A quality score for each program measure is computed for each provider using the following formula:

   a) Numerator = Eligible members meeting criteria

   b) Denominator = Total members eligible

   c) Numerator ÷ Denominator: The individual provider's quality score for each program measure

2. Compare the individual provider's quality score to the plan goal for quality. The payment for services will be calculated once the plan goal is met, based upon the Numerator.

   For measures with no specific plan goal, a flat fee will be paid for each service completed.

BCN Commercial HMO payment table

QUALITY INCENTIVE MEASURES	PLAN GOAL	PAYOUT
Breast cancer screening	80%	$100
Childhood immunizations — combo 10	63%	$400
Weight assessment and counseling for children: BMI percentile, counseling for nutrition and physical activity	63%	$150
Comprehensive diabetes care: HbA1c < 8%	68%	$250
Comprehensive diabetes care: monitoring for nephropathy	90%	$125
Controlling high blood pressure for hypertension	75%	$100
Depression management — PHQ9 testing	Flat Fee	$200
Smoking/tobacco cessation counseling	Flat Fee	$30

BLUE CROSS BLUE SHIELD OF MICHIGAN AND BLUE CARE NETWORK
2016 PAYOUT SUMMARY — MEDICARE

Medicare Advantage payment calculation

Program payments for each eligible provider are calculated using the following methodology.

1. Quality score: A quality score for each program measure is computed for each provider by determining:
   - Numerator = Eligible members meeting criteria
   - Denominator = Total members eligible
   - Numerator ÷ Denominator: The individual provider's quality score for each program measure
2. Compare the quality score for each measure to the **CMS star rating scale** for that measure to determine a star score for each measure.
3. Average the star scores for all measures to determine an overall star rating by provider.
4. Convert the overall star rating into a per-member-per-month payment using the **Medicare Advantage payment table**.

Note: Providers are scored separately for BCN Advantage and Medicare Advantage PPO products.
See next page for **CMS star rating scale** and **Medicare Advantage payment table**.

BLUE CROSS BLUE SHIELD OF MICHIGAN AND BLUE CARE NETWORK
2016 PAYOUT SUMMARY — MEDICARE

Medicare Advantage payment calculation
Example #1: "Dr. A"

DR. A QUALITY SCORES BY MEASURE:	NUMERATOR	DENOMINATOR	SCORE	STARS	WEIGHTED STARS
Adult BMI assessment	32	32	100%	5	5
Breast cancer screening	15	15	100%	5	5
Colorectal cancer screening	25	35	72%	4	4
Comprehensive diabetes care: HbA1c ≤ 9% (weighted x 3)	11	12	90%	5	5 5 5
Comprehensive diabetes care: monitoring for nephropathy	10	10	100%	5	5
Controlling high blood pressure for hypertension	0	0	n/a	n/a	n/a
Disease modifying anti-rheumatic drug therapy for rheumatoid arthritis	1	1	100%	5	5
Medication adherence for diabetes medications (weighted x 3)	5	6	83%	5	5 5 5
Medication adherence for hypertension medications (weighted x 3)	12	16	75%	3	3 3 3
Medication adherence for cholesterol medications (weighted x 3)	20	24	83%	5	5 5 5
Total stars					78
Number of measures with a star score for Dr. A					17
Average star rating					4.59
Per-member-per-month payment					$7.00
Dr. A's 2016 member months					1,000
Dr. A's total 2016 program dollars earned					**$7,000**

- Dr. A scored an average of 4.59 stars for 2016
- 4.59 stars places Dr. A in the 4.5 to 4.99 star range
- Dr. A will earn $7 per member per month for 2016

BLUE CROSS BLUE SHIELD OF MICHIGAN AND BLUE CARE NETWORK
2016 PAYOUT SUMMARY — MEDICARE

Medicare Advantage payment calculation
Example #2: "Dr. B"

	Scoring
Total stars	59
Number of measures with a star score for Dr. B	18
Average star rating 2016 for Dr. B	3.28
Average star rating 2015 for Dr. B	2.17
Dr. B star improvement 2015 – 2016	1.11
Per-member-per-month payment	$2.00
Dr. B's 2016 member months	500
Dr. B's total 2016 program dollars earned	**$1,000**

- Dr. B scored an average of 3.28 stars, below the 3.5 stars threshold for 2016
- Dr. B showed a 1.11 star improvement from 2015 to 2016
- The 1.11 star improvement is divided by 0.5 to determine how many half-star increments Dr. B improved
- 1.11/0.5 = 2.22, the 2.22 is rounded down to the nearest whole number which is 2
- Dr. B improved 2 half-star increments
- Dr. B will earn two times the improvement per member per month of $1
- Dr. B will earn $2 per member per month for 2016

Medicare Advantage payment calculation
Example #3: "Dr. C"

	Scoring
Total stars	31
Number of measures with a star score for Dr. C	12
Average star rating 2016 for Dr. C	2.58
Average star rating 2015 for Dr. C	3.08
Dr. C star improvement 2015 – 2016	None
Per-member-per-month payment (Dr. C showed no improvement)	$0
Dr. C's 2016 member months	750
Dr. C's total 2016 program dollars earned	**$0**

- Dr. C scored average of 2.58 stars, below the 3.5 stars threshold for 2016
- Dr. C showed no improvement from 2015 to 2016
- Dr. C does not qualify for a program payment for 2016

2016 PROGRAM SCHEDULE

JAN	FEB	MAR	APR	MAY	JUN	JUL	AUG	SEP	OCT	NOV	DEC	JAN	FEB	MAR	APR	MAY	JUN	JUL	AUG

Measurement period: January to December, 2016

HEB/Supplemental Date: January 2016 to Early/Mid-January 2017

Claim/EMR Submission: January 2016 to February 2017

Payment: May to August 2017

Note: See Page 24 for the schedule for the depression management quality measure.

PROGRAM QUALIFICATIONS

1. The primary care physician or physician organization must sign the BCN 2016 Medical Services Agreement to participate in the BCN Commercial and BCN Advantage Performance Recognition Programs and the Blue Cross Medicare Advantage PPO Provider Agreement to participate in the Blue Cross Medicare Plus Blue PPO Performance Recognition Program.

2. The primary care physician or physician organization must comply with all terms and conditions of those agreements, including:
   - Providing timely and accurate encounter, referral and claims data
   - Remitting any funds due for prior contract years

3. The primary care physician must be affiliated for the entire 2016 calendar year.

4. The primary care physician must be affiliated at the time of payment to be eligible for any program payments unless the PCP recently retired.

5. The primary care physician or PCP office must have a Health e-Blue℠ sign-on and actively use the program.

6. BCN and Blue Cross retain the right to modify the Performance Recognition Program for any reason and at any time. Modifications may include, but are not limited to:
   - Exclusion or removal of program measures
   - Changes to program calculation methodologies

7. Blue Care Network and Blue Cross conduct periodic random audits on provider data returns. If you are randomly selected to be audited for Health e-Blue data entry or electronic medical records, you must pass the audit in order to be eligible for payment.

PERFORMANCE MEASUREMENT GUIDELINES

- Each primary care physician will be credited for services completed through **Dec. 31, 2016,** to members who meet all measurement requirements, are continuously enrolled with the plan for the entire year and are assigned to a primary care physician whether or not the primary care physician was the member's primary care physician at the time services were provided.

- Credit will be granted to the primary care physician for each component measure only when the specific identified service is documented as provided to the member (by the primary care physician, the member's previous primary care physician or a specialist). Members may be excluded from measures under certain circumstances, such as bilateral mastectomy for breast cancer screening, which should be indicated to Blue Cross or BCN by the primary care physician offices via the Health e-Blue *Treatment Opportunities by Condition/Measure* screen.

- Blue Cross and BCN recognize that many primary care physician offices send reminder letters or may not see certain members in their offices who are identified by Blue Cross or BCN as needing certain services. Such occurrences will not count as credit toward the component measure.

- Each primary care physician's quality performance measurement data comes directly from Blue Cross or BCN's Health Management Program reporting database accessible through Health e-Blue. The Health e-Blue *Treatment Opportunities by Condition/Measure* for the Performance Recognition Program will include:
  - A list of the cohort member population for each component measure that needs a specific health promotion, disease prevention or health management service according to evidence-based medicine
  - **Intervention** opportunities for physicians to supplement Blue Cross or BCN's databases by providing service or exclusion data of which Blue Cross or BCN had no knowledge
  - **A Quality Summary Report or Performance Recognition Program composite score** that shows the monthly quality composite rates for the primary care physician and provider organizations

ADMINISTRATIVE DETAILS

Health e-Blue

Health e-Blue provides a valuable opportunity for provider offices to assess their current performance and return data to Blue Cross or BCN. We accept electronic submission of data through the Healthy e-Blue application, EMR, claims and HEDIS initiatives. Entering missing information will help reduce reporting errors. If your office needs assistance with or has a question about BCN Health e-Blue, please contact Health e-Blue technical support at healtheblue@bcbsm.com. For Blue Cross Health e-Blue questions please contact MAHealtheblue@bcbsm.com.

Please remember that all data entered into Health e-Blue must be for services you provide, not for services ordered, reminders sent or referrals provided.

Distribution of Blue Cross and BCN Performance Recognition Program Payment Reports and Payments

Blue Cross and BCN will make every effort to send the 2016 payment reports and payments by summer 2017.

BCN payments will be made according to BCN's incentive payment policy, subject to the requirements outlined in this document. The primary care physician's payment will be associated with the medical care group the primary care physician is affiliated with as of December 31, 2016.

Reconsideration

Blue Cross and BCN strongly encourage primary care physicians to focus on the ongoing review and data submission using Health e-Blue during each Performance Recognition Program year. In the event any future reconsideration process is provided based on extenuating circumstances, Blue Cross or BCN will notify the affected primary care physician of the terms, conditions and limitations of such a process.

QUESTIONS

If you have questions or concerns about the Performance Recognition Program, please contact your **provider consultant**. You can find contact information for your provider consultant by following these steps:

- Go to bcbsm.com/providers.
- Click on *Contact Us* in the upper right corner of the page.
- Under *Physicians and professionals*, click on *Blue Cross Blue Shield of Michigan* or *Blue Care Network provider contacts*.
- Click on *Provider consultants*.
- Find your provider consultant either on the *physician organization consultants* list or the applicable regional list.

BREAST CANCER SCREENING						
Product lines	**BCN Commercial, BCN Advantage, Blue Cross Medicare Plus Blue PPO**					
Source	HEDIS/CMS stars					
Description	The percentage of women who had a mammogram to screen for breast cancer					
Continuous enrollment	Must be continuously enrolled with the same Blue Cross or BCN plan October 1, 2014 through December 31, 2016					
Age criteria	52 to 74 years of age as of December 31, 2016					
Exclusionary criteria	Women who have had a bilateral mastectomy The following criteria meets bilateral mastectomy: • Bilateral mastectomy • Unilateral mastectomy with bilateral modifier • Two unilateral mastectomies with services dates 14 days or more apart					
Numerator	A mammogram at any time on or between October 1, 2014, and December 31, 2016					
Denominator	The eligible population					
Level of measure	Provider level					
Target: COMM	80%					
Payout: COMM	$100 per service completed for each eligible member					
Target: BCNA/MAPPO	1 star	2 stars	3 stars	4 stars	5 stars	Weight
	< 39%	39 – 62.9%	63 – 73.9%	74 – 79.9%	≥ 80%	1
Payout: BCNA/MAPPO	Per member, per month, based on overall average stars score for Medicare PRP measures					

HEALTH CARE OUTCOMES: PREVENTIVE HEALTH

CHILDHOOD IMMUNIZATIONS – COMBO 10	
Product lines	**BCN Commercial**
Source	HEDIS
Description	The percentage of children 2 years of age who meet the combination 10 criteria on or before their second birthday: • (4) DTaP* vaccinations • (3) IPV* vaccinations • (1) MMR vaccination • (1) VZV vaccination • (3) HiB* vaccinations • (3) Hepatitis B vaccinations • (4) PCV* vaccinations • (1) HepA vaccination • (2 or 3) RV* vaccinations • (2) Influenza** vaccinations *Vaccinations administered prior to 42 days after birth are not counted as a numerator hit. **Vaccinations administered prior to 180 days after birth are not counted as a numerator hit.
Continuous enrollment	Must be continuously enrolled 12 months prior to child's second birthday
Age criteria	Children who turn 2 years of age during 2016
Exclusionary criteria	Children who are documented with an anaphylactic reaction to the vaccine or its components
Numerator	The number of children who completed vaccinations as defined above
Denominator	The eligible population
Level of measure	Provider level
Target: COMM	63%
Payout: COMM	$400 per Combo 10 completed for each eligible member

HEALTH CARE OUTCOMES: PREVENTIVE HEALTH

WEIGHT ASSESSMENT AND COUNSELING FOR CHILDREN: BMI PERCENTILE, COUNSELING FOR NUTRITION AND COUNSELING FOR PHYSICAL ACTIVITY	
Product lines	**BCN Commercial**
Source	HEDIS
Description	Members 3 to 17 years of age who have an active BCN Commercial span through the end of 2016 and had an outpatient visit between January 1, 2016, and December 31, 2016, with a PCP or ObGyn, where BMI percentile, counseling for nutrition and counseling for physical activity were documented in the medical record. The member's outpatient visit was reflected on a claim and the BMI percentile, counseling for nutrition and counseling for physical activity was reflected on a claim, electronic data submission for an EMR or entered in Health e-Blue.
Continuous enrollment	Must be continuously enrolled with BCN for 2016
Age criteria	3 to 17 years of age as of December 31, 2016
Numerator	• BMI percentile documentation during the measurement period (January to December 2016). Documentation in the member's medical record must also include height and weight. • Counseling for nutrition during the measurement period (January to December 2016). • Counseling for physical activity during the measurement period (January to December, 2016).
Denominator	The eligible population
Level of measure	Provider level
Target: COMM	63%
Payout: COMM	$150 per eligible member for whom all services were complete

HEALTH CARE OUTCOMES: PREVENTIVE HEALTH

COLORECTAL CANCER SCREENINGS						
Product lines	**BCN Advantage, Blue Cross Medicare Plus Blue PPO**					
Source	HEDIS/CMS stars					
Description	The percentage of members who had appropriate screening for colorectal cancer					
Continuous enrollment	Must be continuously enrolled with the same Blue Cross/BCN plan for 2015-2016					
Age criteria	51 to 75 years as of December 31, 2016					
Exclusionary criteria	Either of the following any time during the member's history through December 31, 2016 • Colorectal cancer • Total colectomy					
Numerator	One or more screenings for colorectal cancer. Any of the following meet criteria: • Fecal occult blood test during 2016 (digital rectal exams do not count) • Flexible sigmoidoscopy 2012 through 2016 • Colonoscopy 2007 through 2016					
Denominator	The eligible population					
Level of measure	Provider level					
Target: BCNA/MAPPO	1 star	2 stars	3 stars	4 stars	5 stars	Weight
	< 51%	51 – 62.9%	63 – 70.9%	71 – 77.9%	≥ 78%	1
Payout: BCNA/MAPPO	Per member, per month, based on overall average stars score for Medicare PRP measures					

HEALTH CARE OUTCOMES: DISEASE MANAGEMENT

COMPREHENSIVE DIABETES CARE: CONTROLLED HbA1c < 8%	
Product lines	**BCN Commercial**
Source	HEDIS
Description	The percentage of members with diabetes (type 1 or 2) and a documented HbA1c < 8% using the latest lab conducted in 2016
Continuous enrollment	Members must be continuously enrolled with the same BCN plan for 2016
Age criteria	18 to 75 years as of December 2016
Exclusionary criteria	• Diagnosis of gestational or steroid-induced diabetes, in any setting, during 2015 or 2016 and • Did not have a diagnosis of diabetes in 2015 or 2016
Numerator	The number of members with diabetes (type 1 or 2) with an HbA1c < 8.0%. This measure considers the most recent lab conducted in 2016. The member is not compliant if the most recent result is ≥ 8, if the member is missing a result or the test was not done during 2016.
Denominator	All members with diabetes as defined above
Level of measure	Provider level
Target: COMM	68%
Payout: COMM	$250 per service completed for each eligible member

COMPREHENSIVE DIABETES CARE: CONTROLLED HbA1c ≤ 9%						
Product lines	**BCN Advantage, Blue Cross Medicare Plus Blue PPO**					
Source	HEDIS/CMS stars					
Description	The percentage of members with diabetes (type 1 or 2) and a documented HbA1c ≤ 9% using the latest lab conducted in 2016					
Continuous enrollment	Must be continuously enrolled with the same Blue Cross or BCN plan for 2016					
Age criteria	18 to 75 years as of December 2016					
Exclusionary criteria	• Diagnosis of gestational or steroid-induced diabetes, in any setting, during 2015 or 2016 and • Did not have a diagnosis of diabetes in 2015 or 2016					
Numerator	The number of members with diabetes (type 1 or 2) with an HbA1c ≤9.0% This measure considers the most recent lab conducted in 2016. The member is not compliant if the most recent result is > 9, the member is missing a result or the test was not done during 2016.					
Denominator	All members with diabetes as defined above					
Level of measure	Provider level					
Target: BCNA/MAPPO	1 star	2 stars	3 stars	4 stars	5 stars	**Weight**
	< 49%	49 – 59.9%	60 – 70.9%	71 – 83.9%	≥ 84%	**3**
Payout: BCNA/MAPPO	Per member, per month, based on overall average stars score for Medicare PRP measures					

HEALTH CARE OUTCOMES: DISEASE MANAGEMENT

COMPREHENSIVE DIABETES CARE: MONITORING FOR NEPHROPATHY						
Product lines	**BCN Commercial, BCN Advantage, Blue Cross Medicare Plus Blue PPO**					
Source	HEDIS/CMS stars					
Description	The percentage of members with diabetes (type 1 or 2) who have had one of the following: • A nephropathy screening or monitoring test (test for urine albumin or protein) in 2016 • Medical treatment for nephropathy in 2016 • Visit with a nephrologist in 2016 • At least one dispensing event of ACEI/ARB medication in 2016					
Continuous enrollment	Members must be continuously enrolled with the same Blue Cross or BCN plan for 2016					
Age criteria	18 to 75 years as of December 2016					
Exclusionary criteria	• Diagnosis of gestational or steroid-induced diabetes, in any setting, during 2015 or 2016 and • Did not have a diagnosis of diabetes in 2015 or 2016					
Numerator	Members with diabetes (type 1 or 2) who have had one of the following: • A nephropathy screening or monitoring test (test for urine albumin or protein) in 2016 • Medical treatment for nephropathy in 2016 • Visit with a nephrologist in 2016 • At least one dispensing event of ACEI/ARB medication in 2016					
Denominator	All members with diabetes as defined above					
Level of measure	Provider level					
Target: COMM	90%					
Payout: COMM	$125 per service completed for each eligible member					
Target: BCNA/MAPPO	1 star	2 stars	3 stars	4 stars	5 stars	Weight
	< 85%	85 – 88.9%	89 – 92.9%	93 – 96.9%	≥ 97%	1
Payout: BCNA/MAPPO	Per member, per month, based on overall average stars score for Medicare PRP measures					

HEALTH CARE OUTCOMES: DISEASE MANAGEMENT

CONTROLLING HIGH BLOOD PRESSURE: HYPERTENSION						
Product lines	**BCN Commercial, BCN Advantage, Blue Cross Medicare Plus Blue PPO**					
Source	BCN and Blue Cross clinical guidelines					
Description	Members 18 to 85 years of age who were diagnosed with hypertension anytime on or before June 30, 2016 Control is demonstrated by: • Members 18 to 59 years of age with BP < 140/90 mm Hg • Members 60 to 85 years of age with diagnosis of diabetes with BP < 140/90 mm Hg • Members 60 to 85 years of age without a diagnosis of diabetes with BP < 150/90 mm Hg The last blood pressure reading between July 1, 2016 and December 31, 2016, will be counted.					
Continuous enrollment	Must be continuously enrolled with the same Blue Cross or BCN plan for 2016					
Age criteria	Members 18 to 85 years as of December 31, 2016					
Numerator	Members as defined above					
Denominator	The eligible population					
Level of measure	Provider level					
Target: COMM	75%					
Payout: COMM	$100 per service completed for each eligible member					
Target: BCNA/MAPPO	1 star	2 stars	3 stars	4 stars	5 stars	Weight

HEALTH CARE OUTCOMES: DISEASE MANAGEMENT

MEDICATION ADHERENCE FOR DIABETES MEDICATIONS						
Product lines	**BCN Advantage, Blue Cross Medicare Plus Blue PPO**					
Source	CMS stars					
Description	The percentage of adult Medicare members who adhere to their prescribed drug therapy across the following classes of oral diabetes medications; biguanides, sulfonylureas, thiazolidinediones, DPP-IV inhibitors, incretin mimetics, meglitinides, and SGLT2 inhibitors					
Continuous enrollment	Members must be continuously enrolled with the same Blue Cross or BCN plan for 2016					
Age criteria	18 years of age by December 31, 2016					
Numerator	Number of adult members 18 years or older enrolled during 2016 with a proportion of days covered at 80 percent or more across the classes of oral diabetes medications Members are excluded if they have one or more fills for insulin during the measurement period.					
Denominator	Number of adult members 18 years or older enrolled during 2016 with at least two fills of medication across any of the drug classes					
Level of measure	Provider level					
Target: BCNA/MAPPO	1 star	2 stars	3 stars	4 stars	5 stars	**Weight**
	< 60%	60 – 68.9%	69 – 74.9%	75 – 81.9%	≥ 82%	**3**
Payout: BCNA/MAPPO	Per member, per month, based on overall average stars score for Medicare PRP measures					

MEDICATION ADHERENCE FOR HYPERTENSION MEDICATIONS						
Product lines	**BCN Advantage, Blue Cross Medicare Plus Blue PPO**					
Source	CMS stars					
Description	The percentage of adult Medicare members who adhere to their prescribed drug therapy for ACEI or ARB medications					
Continuous enrollment	Members must be continuously enrolled with the same Blue Cross or BCN plan for 2016					
Age criteria	18 years of age by December 31, 2016					
Numerator	Number of adult members 18 years of age or older enrolled during 2016 with a proportion of days covered at 80 percent or more for ACEI or ARB medications					
Denominator	Number of adult members 18 years or older enrolled during 2016 with at least two fills of either the same medication or medications with the same active ingredient					
Level of measure	Provider level					
Target: BCNA/MAPPO	1 star	2 stars	3 stars	4 stars	5 stars	**Weight**
	< 58%	58 – 72.9%	73 – 76.9%	77 – 80.9%	≥ 81%	**3**
Payout: BCNA/MAPPO	Per member, per month, based on overall average stars score for Medicare PRP measures					

HEALTH CARE OUTCOMES: DISEASE MANAGEMENT

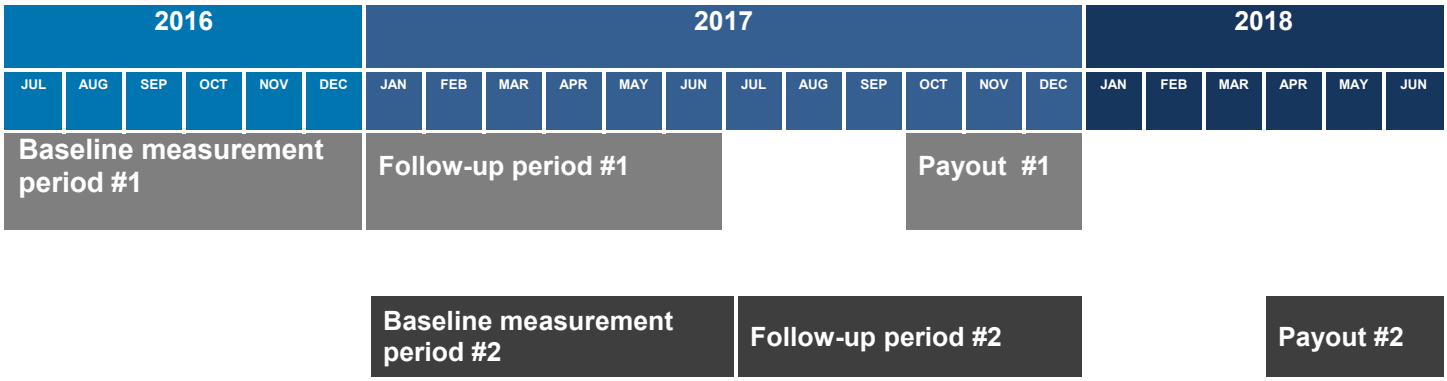
MEDICATION ADHERENCE FOR CHOLESTEROL MEDICATIONS						
Product lines	**BCN Advantage, Blue Cross Medicare Plus Blue PPO**					
Source	CMS stars					
Description	The percentage of adult Medicare members who adhere to their prescribed drug therapy for statin cholesterol medications					
Continuous enrollment	Members must be continuously enrolled with the same Blue Cross or BCN plan for 2016					
Age criteria	18 years of age by December 31, 2016					
Numerator	Number of adult members 18 years of age or older enrolled during the measurement period with a proportion of days covered at 80 percent or more for statin cholesterol medications					
Denominator	Number of adult members 18 years of age or older enrolled during 2016 with at least two fills of either the same statin medication or medications with the same active ingredient.					
Level of measure	Provider level					
Target: BCNA/MAPPO	1 star	2 stars	3 stars	4 stars	5 stars	**Weight**
	< 50%	50 – 60.9%	61 – 72.9%	73 – 78.9%	≥ 79%	**3**
Payout: BCNA/MAPPO	Per member, per month, based on overall average stars score for Medicare PRP measures					

HEALTH CARE OUTCOMES: DISEASE MANAGEMENT

SMOKING/TOBACCO CESSATION COUNSELING	
Product lines	**BCN Commercial**
Source	BCN Medical Administration
Description	Members who use tobacco and receive face-to-face cessation advice, information on medications and strategies to help them quit, and a follow-up letter from the physician to review the information discussed
Continuous enrollment	Not required
Age criteria	Members 18 years of age or older as of January 1, 2016
Numerator	Members as defined above who are smokers or tobacco users
Denominator	The eligible population
Level of measure	Provider level
Target: COMM	Flat fee per member who meets measure
Payout: COMM	$30 per service completed for each eligible member
Additional Details:	PCPs were provided with a sample member letter in the January-February 2016 *BCN Provider News* to send upon completion of an office visit that summarized the following that took place during the visit: • Face-to-face tobacco cessation advice • Information and medications that can assist the member in tobacco cessation • Tobacco cessation strategies to increase the member's chance of success These letters must be sent to the member upon completion of the visit and a copy must also be faxed to BCN at 1-**866-637-4972** to receive credit for this measure. The letter must be in the format provided by BCN in order to receive credit. A template for this letter can be found at **bcbsm.com**. 1. Login to Provider Secured Services. 2. Click on *BCN Provider Publications and Resources*. 3. Click on Forms and look under *Member materials*.

HEALTH CARE OUTCOMES: DISEASE MANAGEMENT

DEPRESSION MANAGEMENT: PHQ9 TESTING	
Product lines	**BCN Commercial**
Source	BCN Medical Administration
Description	Members who have any depressive condition and had a PHQ9 administered during the baseline period scoring greater than or equal to 10 and had a follow-up PHQ9 administered during the follow-up period, scoring below 5.
Continuous enrollment	Members must be continuously enrolled with the same BCN plan for the baseline and follow-up periods
Age criteria	12 years of age or older as of the first day of the baseline measurement period
Numerator	The last qualifying encounter (PHQ9 screening with a score < 5) in the follow-period determines the numerator events for the performance measure.
Denominator	The first qualifying encounter (PHQ9 Screening with a score ≥ 10) in the baseline determines the denominator events for the performance measure.
Level of measure	Provider level
Target: COMM	Flat fee per member who meets measure
Payout: COMM	$200 per service completed for each eligible member
Additional Details:	Measurement periods, follow-up periods and payouts will be on a rolling basis as outlined below:



CMS MILLION HEARTS INCENTIVE PROGRAM

Blue Care Network has implemented a program to prevent cardiovascular disease. The program is designed for BCN Advantage members, ages 40 and over, who have a history of cardiovascular disease or diabetes. The focus of the program is to reduce the morbidity and mortality related to cardiovascular disease in these members.

The program incorporates clinical practice guidelines for the management of ischemic heart disease and diabetes mellitus following the guiding principles behind the nation Million Hearts™ initiative. Million Hearts is a national initiative to prevent 1 million heart attacks and strokes over five years. It is led by the U.S. Department of Health and Human Services, the Centers for Disease Control and Prevention and the Centers for Medicare & Medicaid Services in partnership with other federal agencies.

CMS Million Hearts payment table

Quality incentive measures	Plan goal	Payout
Aspirin or antiplatelet therapy	Flat fee	$25
Blood pressure control	Flat fee	$25
Tobacco cessation counseling	Flat fee	$25

CMS Million Hearts payment calculation

CMS Million Hearts requires no specific plan goal. A flat fee is paid for each service completed.

CMS Million Hearts program qualifications

Providers must meet the Performance Recognition Program qualifications in order to be considered for a CMS Million Hearts incentive payment.

Providers can locate Million Hearts members in Health e-Blue under the Treatment Opportunity by Condition/Measures.

CMS Million Hearts data submission options

- Submit a claim with an appropriate CPT II code
- Health e-Blue entry
- Electronic medical record exchange

CMS MILLION HEARTS PROVIDER INCENTIVE

2017 Performance Recognition Program

PROVIDER INCENTIVE PROGRAM FOR:

- **BCN Commercial HMO**
- **BCN Advantage℠ HMO-POS**
- **BCBSM Medicare Plus Blue℠ PPO**

CONTENTS

2017 PERFORMANCE RECOGNITION PROGRAM

The Provider Performance Recognition Program rewards Blue Care Network commercial providers and Medicare Advantage providers for both Blue Cross Blue Shield of Michigan and BCN for their role in helping Blue Cross and BCN achieve the objectives of the Healthcare Effectiveness Data and Information Set, or HEDIS®, and the Centers for Medicare & Medicaid Services' star ratings program. These objectives include:

- Better care
- Healthier people and communities
- Affordable care

Each program rewards providers who encourage their patients to get preventive screenings and procedures, such as eye exams and mammograms, and for achieving patient outcomes such as ensuring diabetic members have their blood sugar controlled.

Our philosophy is to use meaningful payments to encourage positive clinical results as well as increase HEDIS outcomes and CMS star ratings.

The components of the program, including the performance measures that are based on HEDIS benchmarks, are described in this booklet.

We encourage primary care physicians or PCP offices to have a Health e-Blue℠ sign-on and actively use the program.

BLUE CROSS BLUE SHIELD OF MICHIGAN AND BLUE CARE NETWORK
2017 PAYOUT SUMMARY

Payment calculation

Payments for each eligible provider are calculated using the following method.

For measures with a goal:

1. Quality score: A quality score for each program measure is computed for each provider using the following formula:
   a) Numerator = Eligible members meeting criteria
   b) Denominator = Total members eligible
   c) Numerator ÷ Denominator: The individual provider's quality score for each program measure

2. Compare the individual provider's quality score to the plan goal for quality. The payment for services will be calculated once the plan goal is met, based upon the numerator.

For measures with no specific goal, a flat fee will be paid for each service completed.

Payment table

QUALITY INCENTIVE MEASURES	BCN COMMERCIAL		MEDICARE ADVANTAGE℠	
	Goal	Payout	Goal	Payout
Breast cancer screening	80%	$125	76%	$50

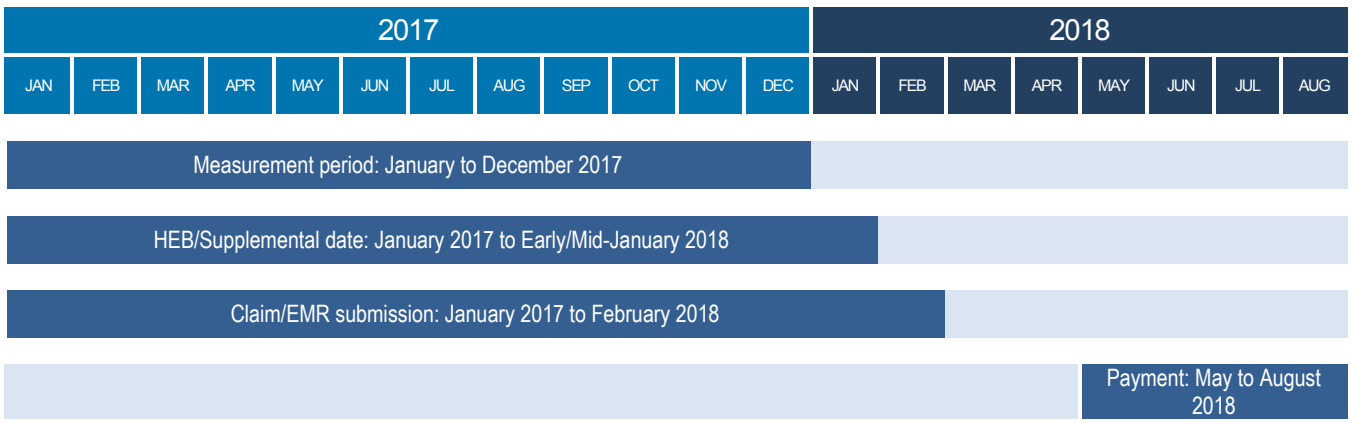
2017 PROGRAM SCHEDULE



Note: See Page 16 for the depression management quality measure schedule.

BLUE CARE NETWORK COMMERCIAL
2017 MARKETPLACE MEMBERSHIP PAYOUT

To recognize the added effort required in managing the Marketplace population of members, BCN is offering a premium to providers who have a larger Marketplace membership and continue to meet performance goals. Providers whose assigned BCN Commercial membership is made up of ≥ 20 percent marketplace members will receive a 15 percent premium on Performance Recognition Program payments earned.

BCN will alert providers who qualify for this premium (based upon total 2016 BCN Commercial member months) at the start of the 2017 measurement year.

Example

Dr. A has 1,000 total BCN Commercial member months in 2016 and 250 of those member months were from the Marketplace population of members (25 percent of the total) and therefore qualifies for the Marketplace premium. Dr. A's performance by measure is outlined below.

QUALITY INCENTIVE MEASURES	Goal	Payout	Dr. A Score	Goal Met or Missed?	Dr. A Numerator	PRP Payment
Breast cancer screening	80%	$125	82%	Met	30	$3,750
Childhood immunizations — Influenza	flat fee	$50	n/a	n/a	2	$100
Comprehensive diabetes care: eye examination	flat fee	$25	n/a	n/a	2	$50
Comprehensive diabetes care: HbA1c < 8%	66%	$250	78%	Met	8	$2,000
Comprehensive diabetes care: monitoring for nephropathy	93%	$150	56%	Missed	5	$0
Depression management — PHQ9 testing	flat fee	$200	n/a	n/a	2	$400
Follow-up care for children with prescribed ADHD medication - initiation phase	47%	$100	50%	Met	1	$100
Use of imaging studies for low back pain	83%	$150	100%	Met	1	$150
Weight assessment & counseling for children: BMI percentile	83%	$50	83%	Met	10	$500
Weight assessment & counseling for children: counseling for nutrition	78%	$75	83%	Met	10	$750
Weight assessment & counseling for children: counseling for physical activity	63%	$100	67%	Met	8	$800
Well care visits – first 15 months	89%	$100	100%	Met	2	$200
Total base PRP payment						**$8,800**
15% Marketplace premium						**$1,320**
Total PRP payment with Marketplace premium						**$10,120**

Dr. A earned a 2017 base PRP payment of $8,800 plus a 15 percent premium of $1,320 to add up to a total payment of $10,120.

PROGRAM QUALIFICATIONS

1. The primary care physician or physician organization must sign the BCN 2017 Medical Services Agreement to participate in the BCN Commercial and BCN Advantage Performance Recognition Programs and the Blue Cross Medicare Advantage PPO Provider Agreement to participate in the Blue Cross Medicare Plus Blue PPO Performance Recognition Program.

2. The primary care physician or physician organization must comply with all terms and conditions of those agreements, including:
   - Providing timely and accurate encounter, referral and claims data
   - Remitting any funds due for prior contract years

3. The primary care physician must be affiliated for the entire 2017 calendar year.

4. Primary care physicians must have attributed or assigned members to participate in the program.

5. The primary care physician must be affiliated at the time of payment to be eligible for any program payments unless the PCP recently retired.

6. BCN and Blue Cross retain the right to modify the Performance Recognition Program for any reason and at any time. Modifications may include but are not limited to:
   - Exclusion or removal of program measures
   - Changes to program calculation methods

PERFORMANCE MEASUREMENT GUIDELINES

Measurement timeframe

Each primary care physician will be credited for services completed through **December 31, 2017** to members who meet all measurement requirements, are continuously enrolled with the plan for the entire year and are assigned to a primary care physician whether or not the primary care physician was the member's primary care physician at the time services were provided.

Exclusions

Members may be excluded from measures under certain circumstances such as bilateral mastectomy for breast cancer screening, which should be indicated to Blue Cross or BCN by the primary care physician offices via the Health e-Blue *Treatment Opportunities by Condition/Measure* screen.

Members in hospice during 2017 are excluded from the PRP program.

Qualifying Services

Credit will be granted to the primary care physician for each component measure only when the specific identified **service is documented as provided** to the member (by the primary care physician, the member's previous primary care physician or a specialist).

Blue Cross and BCN recognize that many primary care physician offices send **reminder letters** or may not see certain members in their offices who are identified by Blue Cross or BCN as needing certain services. Such occurrences **won't count** as credit toward the component measure.

Reporting

Each primary care physician's quality performance measurement data comes directly from Blue Cross or BCN's Health Management Program reporting database accessible through Health e-Blue. The Health e-Blue *Treatment Opportunities by Condition/Measure* for the Performance Recognition Program will include:

- A list of the cohort member population for each component measure that needs a specific health promotion, disease prevention or health management service according to evidence-based medicine
- **Intervention** opportunities for physicians to supplement Blue Cross or BCN's databases by providing service or exclusion data of which Blue Cross or BCN had no knowledge
- **A Quality Summary Report or Performance Recognition Program composite score** that shows the monthly quality composite rates for the primary care physician and provider organizations

ADMINISTRATIVE DETAILS

Health e-Blue℠

Health e-Blue provides a valuable opportunity for provider offices to assess their current performance and return data to Blue Cross or BCN. We accept electronic submission of data through the Healthy e-Blue application, EMR, claims and HEDIS initiatives. Entering missing information will reduce reporting errors. If your office has a question about BCN Health e-Blue, please contact Health e-Blue technical support at healtheblue@bcbsm.com. For Blue Cross Health e-Blue questions, contact MAHealtheblue@bcbsm.com.

Please remember that all data entered into Health e-Blue must be for services you provide, not for services ordered, reminders sent or referrals provided.

Distribution of Blue Cross and BCN Performance Recognition Program Payment Reports and Payments

Blue Cross and BCN will make every effort to send the 2017 payments and payment reports by **summer 2017**. BCN payments will be made according to BCN's incentive payment policy, subject to the requirements outlined in this document. The primary care physician's payment will be associated with the medical care group the primary care physician is affiliated with as of **December 31, 2017.**

Reconsideration

Blue Cross and BCN strongly encourage primary care physicians to focus on the ongoing review and data submission using Health e-Blue during each Performance Recognition Program year. In the event any future reconsideration process is provided based on **extenuating circumstances**, Blue Cross or BCN will notify the affected primary care physician of the terms, conditions and limitations of such a process.

QUESTIONS

If you have questions about the Performance Recognition Program, please contact your **provider consultant**. You can find contact information by following these steps:

- Go to bcbsm.com/providers.
- Click on *Contact Us* in the upper right corner of the page.
- Under *Physicians and professionals*, click on *Blue Cross Blue Shield of Michigan* or *Blue Care Network provider contacts*.
- Click on *Provider consultants*.
- Find your provider consultant either on the *physician organization consultants* list or the applicable regional list.

HEALTH CARE OUTCOMES: PREVENTIVE HEALTH

BREAST CANCER SCREENING	
Product lines	**BCN Commercial, BCN Advantage, Blue Cross Medicare Plus Blue PPO**
Source	HEDIS/CMS stars
Description	The percentage of women who had a mammogram to screen for breast cancer
Continuous enrollment	Must be continuously enrolled with the same Blue Cross or BCN plan October 1, 2015 through December 31, 2017
Age criteria	52 to 74 years of age as of December 31, 2017
Exclusionary criteria	Women who have had a bilateral mastectomy The following criteria meets bilateral mastectomy: • Bilateral mastectomy • Unilateral mastectomy with bilateral modifier • Two unilateral mastectomies with services dates 14 days or more apart
Numerator	A mammogram at any time on or between October 1, 2015 and December 31, 2017
Denominator	The eligible population
Target: COMM	80%
Payout: COMM	$125 per service completed for each eligible member
Target: BCNA/MAPPO	76%
Payout: BCNA/MAPPO	$50 per service completed for each eligible member

CHILDHOOD IMMUNIZATIONS – INFLUENZA	
Product lines	**BCN Commercial**
Source	HEDIS
Description	Two influenza vaccinations with different dates of service, administered on or before the second birthday. Vaccinations administered prior to 180 days after birth are not counted as a numerator hit
Continuous enrollment	Must be continuously enrolled 12 months prior to child's second birthday
Age criteria	Children who turn 2 years of age during 2017
Exclusionary criteria	Children who are documented with an anaphylactic reaction to the vaccine or its components
Numerator	The number of children who completed vaccinations as defined above
Denominator	The eligible population
Target: COMM	Flat fee per member who meets measure
Payout: COMM	$50 per eligible member for whom all services were complete (not payable per vaccination)

HEALTH CARE OUTCOMES: PREVENTIVE HEALTH

COLORECTAL CANCER SCREENINGS	
Product lines	**BCN Advantage, Blue Cross Medicare Plus Blue PPO**
Source	HEDIS/CMS stars
Description	The percentage of members who had appropriate screening for colorectal cancer
Continuous enrollment	Must be continuously enrolled with the same Blue Cross/BCN plan for 2016-2017
Age criteria	51 to 75 years as of December 31, 2017
Exclusionary criteria	Either of the following any time during the member's history through December 31, 2017 • Colorectal cancer • Total colectomy
Numerator	One or more screenings for colorectal cancer. Any of the following meet criteria: • Fecal occult blood test during 2017 (digital rectal exams do not count) • Flexible sigmoidoscopy 2013 through 2017 • Colonoscopy 2008 through 2017 • FIT-DNA (Cologuard®) 2015 through 2017 • CT Colonography 2013 through 2017
Denominator	The eligible population
Target: BCNA/MAPPO	78%
Payout: BCNA/MAPPO	$50 per eligible member for whom all services were complete

WEIGHT ASSESSMENT AND COUNSELING FOR CHILDREN: BMI PERCENTILE	
Product lines	**BCN Commercial**
Source	HEDIS
Description	Members 3 to 17 years of age who have an active BCN Commercial span through the end of 2017 and had an outpatient visit between January 1, 2017, and December 31, 2017, with a PCP or OB-GYN, where BMI percentile was documented in the medical record The member's outpatient visit was reflected on a claim and the BMI percentile was reflected on a claim, electronic data submission for an EMR or entered in Health e-Blue
Continuous enrollment	Must be continuously enrolled with BCN for 2017
Age criteria	3 to 17 years of age as of December 31, 2017
Exclusionary criteria	Members who have a diagnosis of pregnancy during the measurement year
Numerator	BMI percentile documentation during the measurement period (January to December 2017) Documentation in the member's medical record must also include height and weight
Denominator	The eligible population
Target: COMM	83%
Payout: COMM	$50 per eligible member for whom all services were complete

HEALTH CARE OUTCOMES: PREVENTIVE HEALTH

WEIGHT ASSESSMENT AND COUNSELING FOR CHILDREN: COUNSELING FOR NUTRITION	
Product lines	**BCN Commercial**
Source	HEDIS
Description	Members 3 to 17 years of age who have an active BCN Commercial span through the end of 2017 and had an outpatient visit between January 1, 2017 and December 31, 2017, with a PCP or OB-GYN, where BMI counseling for nutrition was documented in the medical recordThe member's outpatient visit was reflected on a claim and the counseling for nutrition was reflected on a claim, electronic data submission for an EMR or entered in Health e-Blue
Continuous enrollment	Must be continuously enrolled with BCN for 2017
Exclusionary criteria	Members who have a diagnosis of pregnancy during the measurement year
Age criteria	3 to 17 years of age as of December 31, 2017
Numerator	Counseling for nutrition during the measurement period — January to December 2017
Denominator	The eligible population
Target: COMM	78%
Payout: COMM	$75 per eligible member for whom all services were complete

WEIGHT ASSESSMENT AND COUNSELING FOR CHILDREN: COUNSELING FOR PHYSICAL ACTIVITY	
Product lines	**BCN Commercial**
Source	HEDIS
Description	Members 3 to 17 years of age who have an active BCN Commercial span through the end of 2017 and had an outpatient visit between January 1, 2017 and December 31, 2017 with a PCP or OB-GYN, where counseling for physical activity was documented in the medical record The member's outpatient visit was reflected on a claim and the counseling for physical activity was reflected on a claim, electronic data submission for an EMR or entered in Health e-Blue
Continuous enrollment	Must be continuously enrolled with BCN for 2017
Age criteria	3 to 17 years of age as of December 31, 2017
Exclusionary criteria	Members who have a diagnosis of pregnancy during the measurement year
Numerator	Counseling for physical activity during the measurement period (January to December, 2017)
Denominator	The eligible population
Target: COMM	63%
Payout: COMM	$100 per eligible member for whom all services were complete

HEALTH CARE OUTCOMES: PREVENTIVE HEALTH

WELL CARE VISITS – FIRST 15 MONTHS	
Product lines	**BCN Commercial**
Source	HEDIS
Description	Percentage of children with 6 or more well-child visits in the first 15 months of life
Continuous enrollment	Must be continuously enrolled 31 days of age through 15 months
Age criteria	Children who turn 15 months during 2017
Numerator	The number of children who completed six or more well-care visits with a primary care physician in the first 15 months of life with different dates of service
Denominator	The eligible population
Target: COMM	89%
Payout: COMM	$100 per eligible member for whom all services were complete

HEALTH CARE OUTCOMES: DISEASE MANAGEMENT

COMPREHENSIVE DIABETES CARE: RETINAL EYE EXAMS	
Product lines	**BCN Commercial, BCN Advantage, Blue Cross Medicare Plus Blue PPO**
Source	HEDIS
Description	The percentage of members with diabetes (Type 1 or 2) and a documented retinal eye exam
Continuous enrollment	Members must be continuously enrolled with the same BCN plan for 2017
Age criteria	18 to 75 years as of December 2017
Exclusionary criteria	Diagnosis of gestational or steroid-induced diabetes, in any setting, during 2016 or 2017
Numerator	The number of members with diabetes (Type 1 or 2) with a retinal eye exam during 2017 or a retinal eye exam with negative results during 2016
Denominator	All members with diabetes as defined above
Target: COMM	Flat fee per member who meets measure
Payout: COMM	$25 per service completed for each eligible member
Target: BCNA/MAPPO	Flat fee per member who meets measure
Payout: BCNA/MAPPO	$25 per service completed for each eligible member
Additional Details	This measure is payable to the provider who performs the service (if an eye care professional performs the service, he or she is eligible for the incentive, not the PCP). All results must be submitted in order to qualify for this incentive

COMPREHENSIVE DIABETES CARE: CONTROLLED HbA1c < 8%	
Product lines	**BCN Commercial**
Source	HEDIS
Description	The percentage of members with diabetes (Type 1 or 2) and a documented HbA1c < 8% using the latest lab conducted in 2017
Continuous enrollment	Members must be continuously enrolled with the same BCN plan for 2017
Age criteria	18 to 75 years as of December 2017
Exclusionary criteria	Diagnosis of gestational or steroid-induced diabetes, in any setting, during 2016 or 2017
Numerator	The number of members with diabetes (Type 1 or 2) with an HbA1c < 8.0%. This measure considers the most recent lab conducted in 2017. The member isn't compliant if the most recent result is ≥ 8, if the member is missing a result or the test was not done during 2017
Denominator	All members with diabetes as defined above
Target: COMM	66%
Payout: COMM	$250 per service completed for each eligible member

HEALTH CARE OUTCOMES: DISEASE MANAGEMENT

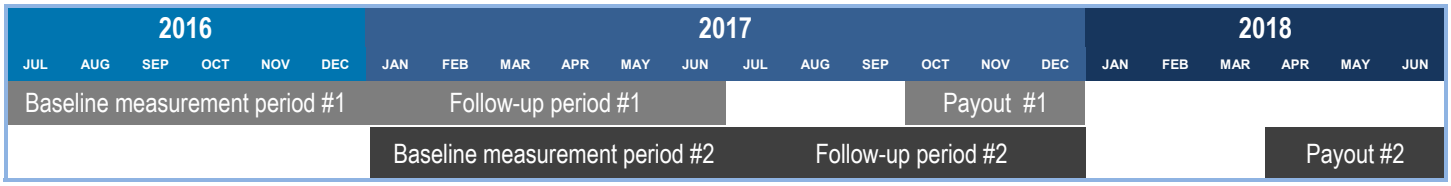
COMPREHENSIVE DIABETES CARE: CONTROLLED HbA1c ≤ 9%	
Product lines	**BCN Advantage, Blue Cross Medicare Plus Blue PPO**
Source	HEDIS/CMS stars
Description	The percentage of members with diabetes (Type 1 or 2) and a documented HbA1c ≤ 9% using the latest lab conducted in 2017
Continuous enrollment	Must be continuously enrolled with the same Blue Cross or BCN plan for 2017
Age criteria	18 to 75 years as of December 2017
Exclusionary criteria	Diagnosis of gestational or steroid-induced diabetes, in any setting, during 2016 or 2017
Numerator	The number of members with diabetes (Type 1 or 2) with an HbA1c ≤9.0% This measure considers the most recent lab conducted in 2017. The member isn't compliant if the most recent result is > 9, the member is missing a result or the test wasn't done during 2017
Denominator	All members with diabetes as defined above
Target: BCNA/MAPPO	84%
Payout: BCNA/MAPPO	$125 per service completed for each eligible member

COMPREHENSIVE DIABETES CARE: MONITORING FOR NEPHROPATHY	
Product lines	**BCN Commercial, BCN Advantage, Blue Cross Medicare Plus Blue PPO**
Source	HEDIS/CMS stars
Description	The percentage of members with diabetes (Type 1 or 2) who have had one of the following: • A nephropathy screening or monitoring test (test for urine albumin or protein) in 2017 • Medical treatment for nephropathy in 2017 • Visit with a nephrologist in 2017 • At least one dispensing event of ACEI/ARB medication in 2017
Continuous enrollment	Members must be continuously enrolled with the same Blue Cross or BCN plan for 2017
Age criteria	18 to 75 years as of December 2017
Exclusionary criteria	Diagnosis of gestational or steroid-induced diabetes, in any setting, during 2016 or 2017
Numerator	Members with diabetes (Type 1 or 2) who have had one of the following: • A nephropathy screening or monitoring test (test for urine albumin or protein) in 2017 • Medical treatment for nephropathy in 2017 • Visit with a nephrologist in 2017 • At least one dispensing event of ACEI/ARB medication in 2017
Denominator	All members with diabetes as defined above
Target: COMM	93%
Payout: COMM	$150 per service completed for each eligible member
Target: BCNA/MAPPO	97%
Payout: BCNA/MAPPO	$75 per service completed for each eligible member

HEALTH CARE OUTCOMES: DISEASE MANAGEMENT

CONTROLLING HIGH BLOOD PRESSURE: HYPERTENSION	
Product lines	**BCN Advantage, Blue Cross Medicare Plus Blue PPO**
Source	BCN and Blue Cross clinical guidelines
Description	Members 18 to 85 years of age who were diagnosed with hypertension anytime on or before June 30, 2017 Control is demonstrated by: • Members 18 to 59 years of age with BP < 140/90 mm Hg • Members 60 to 85 years of age with diagnosis of diabetes with BP < 140/90 mm Hg • Members 60 to 85 years of age without a diagnosis of diabetes with BP < 150/90 mm Hg The last blood pressure reading prior to December 31, 2017 will be counted The last controlled blood pressure must occur after the date of diagnosis
Continuous enrollment	Must be continuously enrolled with the same Blue Cross or BCN plan for 2017
Age criteria	Members 18 to 85 years as of December 31, 2016
Exclusionary Criteria	For exclusions, please refer to the HEDIS 2017 Specification Document
Numerator	Members as defined above
Denominator	The eligible population
Target: BCNA/MAPPO	86%
Payout: BCNA/MAPPO	$25 per service completed for each eligible member

DEPRESSION MANAGEMENT: PHQ9 TESTING	
Product lines	**BCN Commercial**
Source	BCN Medical Administration
Description	Members who have a PHQ9 administered during the baseline period, scoring greater than or equal to 10 and had a follow-up PHQ9 administered during the follow-up period, scoring below 5 or with a reduction of 50% from the original score
Continuous enrollment	Members must be continuously enrolled for the baseline and follow-up periods
Age criteria	12 years of age or older as of the first day of the baseline measurement period
Numerator	The last qualifying encounter (PHQ9 screening with a score < 5 or a 50% reduction from the original score, to indicate remission) in the follow-up period determines the numerator events for the performance measure
Denominator	The first qualifying encounter (PHQ9 Screening with a score ≥ 10) in the baseline determines the denominator events for the performance measure. Only those scoring ≥ 10 will appear in the Treatment Opportunities panel
Target: COMM	Flat fee per member who meets measure
Payout: COMM	$200 per service completed for each eligible member
Additional Details:	See Appendix 2 for a step-by-step guide on how to enter data to qualify for this measure. We *will not* display the PHQ-9 testing rate on the HEB QSRs when the data become available Measurement periods, follow-up periods and payouts will be on a rolling basis as outlined below:



DISEASE-MODIFYING ANTI-RHEUMATIC DRUG THERAPY FOR RHEUMATOID ARTHRITIS	
Product lines	**BCN Advantage, Blue Cross Medicare Plus Blue PPO**
Source	HEDIS, CMS Stars
Description	The percentage of members 18 years of age or older diagnosed with rheumatoid arthritis who were dispensed at least one ambulatory prescription for a disease-modifying anti-rheumatic drug
Continuous enrollment	Members must be continuously enrolled with the same Blue Cross or BCN plans for 2017
Age criteria	18 to 85 years of age or older as of December 31, 2017
Numerator	Members as defined above
Denominator	The eligible population
Level of measure	Provider level
Target: BCNA/MAPPO	Flat fee per member who meets measure
Payout: BCNA/MAPPO	$100 per service completed for each eligible member

HEALTH CARE OUTCOMES: DISEASE MANAGEMENT

FOLLOW-UP AFTER HOSPITALIZATION WITHIN 3 DAYS OF A MEDICAL DISCHARGE	
Product lines	**BCN Advantage, Blue Cross Medicare Plus Blue PPO**
Source	BCN and BCBSM Medical Administration
Description	The percentage of members who had a follow-up visit with their PCP or specialist within three days of a medical hospital discharge
Continuous enrollment	Members must be continuously enrolled with the same Blue Cross or BCN plans for 2017
Age criteria	18 to 85 years of age or older as of December 31, 2017
Numerator	Members as defined above
Denominator	The eligible population
Level of measure	Provider level
Target: BCNA/MAPPO	Flat fee per member who meets measure
Payout: BCNA/MAPPO	$50 per service completed for each eligible member
Additional Information	The goal of this measure is to aid in medication reconciliation, post discharge and to avoid member readmissions

FOLLOW-UP CARE FOR CHILDREN WITH PRESCRIBED ADHD MEDICATION – INITIATION PHASE	
Product lines	**BCN Commercial**
Source	HEDIS
Description	The percentage of members 6 to 12 years of age as of the Index Prescription Start Date with an ambulatory prescription dispensed for ADHD medication, who had one follow-up visit with practitioner with prescribing authority during the 30-day Initiation Phase
Continuous enrollment	Members must be continuously enrolled for 120 days prior to the IPSD through 30 days after the IPSD
Age criteria	6 to 12 years of age as of December 31, 2017
Exclusionary criteria	Exclude from the denominator for both rates, members with a diagnosis of narcolepsy any time during their history through December 31, 2017
Numerator	Members as defined above
Denominator	The eligible population
Level of measure	Provider level
Target: COMM	47%
Payout: COMM	$100 per service completed for each eligible member
Additional Information	This measure doesn't match HEDIS timeframes. This measure will consider IPSD from January 1, 2017 through December 31, 2017 and will allow for a 30-day runout into 2018 to track follow-up visits for IPSD occurring in the last month of 2017

HEALTH CARE OUTCOMES: DISEASE MANAGEMENT

OSTEOPOROSIS MANAGEMENT IN WOMEN WHO HAD A FRACTURE	
Product lines	**BCN Advantage, Blue Cross Medicare Plus Blue PPO**
Source	HEDIS, CMS Stars
Description	The percentage of women 67 to 85 years of age who suffered a fracture and who had EITHER a bone mineral density test or a prescription for a drug to treat or to prevent osteoporosis in the six months after the fracture The member has to be negative for a diagnosis of fracture for 60 days (two months) prior to the IESD and have appropriate testing or treatment for osteoporosis after the fracture defined by any of the following criteria: • A BMD test on the initial fracture date (IESD) or in the 180-day period after the initial fracture date - OR - • A BMD test during the inpatient stay for the fracture (applies only to fractures requiring hospitalization) - OR - • A dispensed prescription to treat osteoporosis on the initial fracture date or in the 180-day period after the initial fracture date
Continuous enrollment	12 months before the initial fracture date through six months after the initial fracture date
Age criteria	Women 67 to 85 years of age as of December 31, 2017
Exclusionary criteria	Exclude members who had a BMD 730 days prior to IESD, or a claim/encounter for osteoporosis therapy or received a dispensed prescription to treat osteoporosis during the 365 days prior to the IESD
Numerator	Members as defined above
Denominator	The eligible population
Level of measure	Provider level
Target: BCNA/MAPPO	Flat fee per member who meets measure
Payout: BCNA/MAPPO	$100 per service completed for each eligible member

USE OF IMAGING STUDIES FOR LOW BACK PAIN	
Product lines	**BCN Commercial**
Source	HEDIS
Description	The percentage of members with a primary diagnosis of low back pain who didn't have an imaging study (plain X-ray, MRI, CT scan) within 28 days of the diagnosis
Continuous enrollment	Members must be continuously enrolled with the same Blue Cross or BCN plans for 2017
Age criteria	18 to 85 years of age or older as of December 31, 2017
Numerator	Members as defined above
Denominator	The eligible population
Level of measure	Provider level
Target: COMM	83%
Payout: COMM	$150 per service completed for each eligible member
Additional Information	This measure will be based on HEDIS 2016 specifications, not the adjusted, new HEDIS specifications

CMS MILLION HEARTS INCENTIVE PROGRAM

Blue Care Network has implemented a program to prevent cardiovascular disease. The program is designed for BCN Advantage members, ages 40 and older, who have a history of cardiovascular disease or diabetes. The focus of the program is to reduce the morbidity and mortality related to cardiovascular disease in these members.

The program incorporates clinical practice guidelines for the management of ischemic heart disease and diabetes mellitus following the guiding principles of the nation Million Hearts™ initiative. Million Hearts is a national initiative to prevent one million heart attacks and strokes over five years. It is led by the U.S. Department of Health and Human Services, the Centers for Disease Control and Prevention and the Centers for Medicare & Medicaid Services in partnership with other federal agencies.

CMS Million Hearts payment table

Quality incentive measures	Plan goal	Payout
Aspirin or antiplatelet therapy	Flat fee	$25
Blood pressure control	Flat fee	$25
Tobacco cessation counseling	Flat fee	$25

CMS Million Hearts payment calculation

CMS Million Hearts requires no specific plan goal. A flat fee is paid for each service completed.

CMS Million Hearts program qualifications

Providers must meet the Performance Recognition Program qualifications to be considered for a CMS Million Hearts incentive payment.

Providers can locate Million Hearts members in Health e-Blue under the Treatment Opportunity by Condition/Measures.

CMS Million Hearts data submission options

- Submit a claim with an appropriate CPT II code
- Health e-Blue entry
- Electronic medical record exchange

CMS MILLION HEARTS PROVIDER INCENTIVE
QUALITY INCENTIVE MEASURES

ASPIRIN OR ANTIPLATELET THERAPY	
Product lines	**BCN Advantage**
Source	CMS Million Hearts
Description	Members age 40 and over as of December 31, 2017 with a history of diabetes, cardiovascular disease or both who are prescribed or currently taking aspirin or antiplatelet therapy Report CPT II code 4086F for all patients meeting criteria
Level of measure	Provider level
Target: BCNA	Flat fee per member who meets measure
Payout: BCNA	$25 per service completed for each eligible member

BLOOD PRESSURE CONTROL	
Product lines	**BCN Advantage**
Source	CMS Million Hearts
Description	Members age 40 and over as of December 31, 2017 who meet both the systolic and diastolic blood pressure reading requirements: • Members 18 to 59 years of age as of December 31, 2017 whose BP was < 140/90 mm Hg • Members 60 to 85 years of age as of December 31, 2017 with a diagnosis of diabetes whose BP was < 140/90 mm Hg • Members 60 to 85 years of age as of December 31, 2017 without a diagnosis of diabetes whose BP was < 150/90 mm Hg • Systolic blood pressure value report one of the systolic codes – 3074F – SBP < 130 – 3075F – SBP 130-139 – SBP > 140 and < 150 (Needs to be documented in EMR or in HEB. No CPT Cat II codes are available) • Diastolic blood pressure value report one of the diastolic codes – 3078F – DBP < 80 – 3079F – DBP 80-89
Level of measure	Provider level
Target: BCNA	Flat fee per member who meets measure
Payout: BCNA	$25 per service completed for each eligible member

CMS MILLION HEARTS PROVIDER INCENTIVE
QUALITY INCENTIVE MEASURES

SMOKING/TOBACCO CESSATION COUNSELING	
Product lines	**BCN Advantage**
Source	CMS Million Hearts
Description	Members age 40 and over as of December 31, 2017 who are smokers and have been counseled on the importance of quitting smoking Providers can report 'Not a smoker' in Health e-Blue as an Exclusion Reason/Contra-Indication Report CPT II code 4000F or 4004F for each patient identified as a tobacco user and received tobacco cessation counseling
Level of measure	Provider level
Target: BCNA	Flat fee per member who meets measure
Payout: BCNA	$25 per service completed for each eligible member

APPENDIX 1:
COMPARISON SUMMARY OF PHYSICIAN RECOGNITION PROGRAM AND BLUE CROSS COMMERCIAL PPO VALUE-BASED REIMBURSEMENT MEASURES

Based on feedback from our provider partners, the PRP team has worked with the Blue Cross Value Partnerships team to develop a comprehensive list of quality measures that are included in each program. Our hope is that this document will aid in administration of the Blue Cross Blue Shield and Blue Care Network quality incentive programs.

	Physician Recognition Program			Blue Cross Commercial PPO Clinical Quality Value-Based Reimbursement

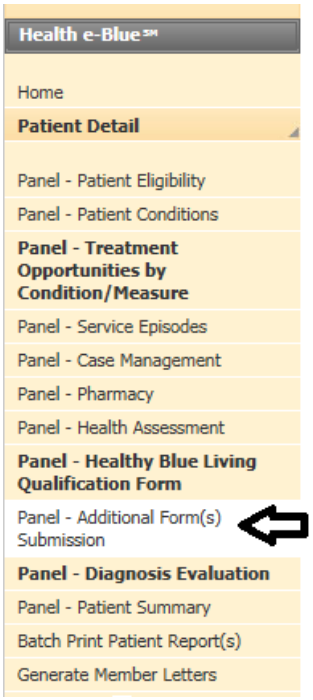
APPENDIX 2:
DEPRESSION MANAGEMENT – PHQ9 TESTING
HEALTH E-BLUE MEASURE ENTRY GUIDE
BCN Commercial Measure

To qualify for the 2017 PRP Depression Management measure, Health e-Blue users must report Blue Care Network Commercial members' Depression Management PHQ9 results using *Panel - Additional Form (s) Submission*.

This guide will walk users through a step-by-step process to enter the required information.

STEP 1: LOGIN
Log in to Blue Care Network - Health e-Blue and click on *Panel- Additional Form (s) Submission* from the left navigation menu.



STEP 2: LOCATE COMMERCIAL PHQ PANEL MEMBERS

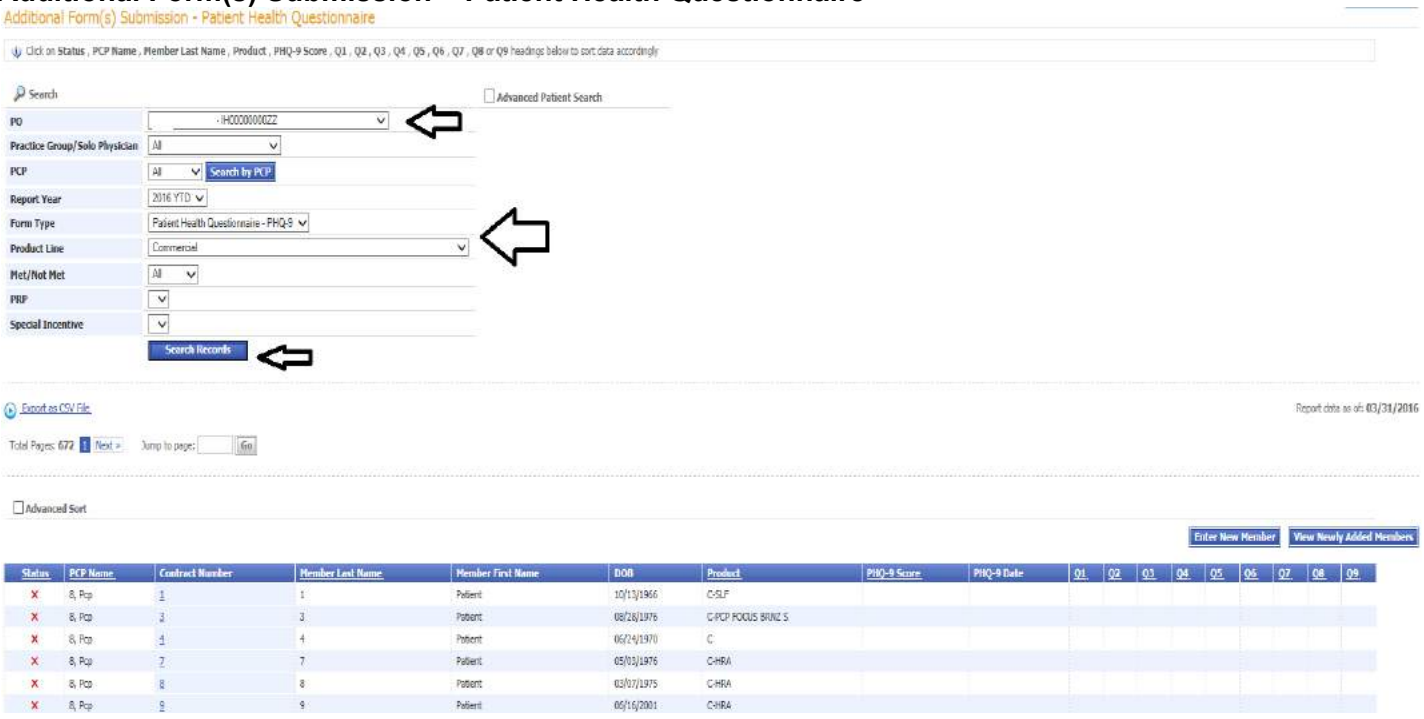
Select the appropriate physician organization, practice group and PCP from the dropdown menus.

In the Form Type dropdown menu, select ***Patient Health Questionnaire – PHQ-9***.

Select ***Commercial*** from the Product Line dropdown menu**.**

Click ***Search Records***.

Additional Form(s) Submission – Patient Health Questionnaire



Note: if you aren't able to find your member, skip down to **STEP 5**.

STEP 3: SELECT COMMERCIAL PHQ PANEL MEMBERS

Select the commercial member in the panel by clicking the ***Contract Number*** and the Patient Health Questionnaire – PHQ9 form will appear.

STEP 4: ENTER PHQ MEMBER RESULTS

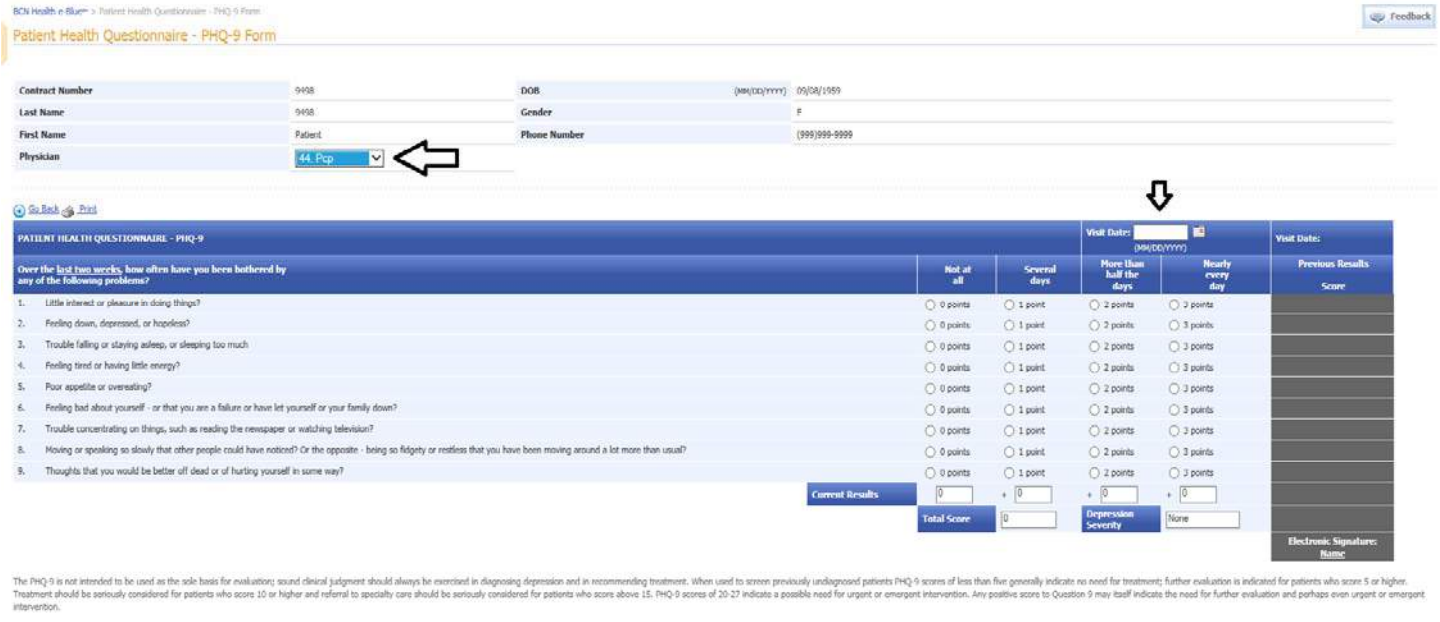
The member information will prepopulate in the PHQ-9 form.

Select the ***Physician*** name from the dropdown menu. The physician name will prepopulate in the PHQ-9 form near the bottom.

Enter the member ***Visit Date*****.**

Enter PHQ-9 results**.**

Patient Health Questionnaire - PHQ-9 Form – data entry screen



STEP 5: ADDING NEW MEMBERS - COMMERCIAL PHQ PANEL MEMBERS

How to add a new member and view newly added members
If you need to add a commercial member, select the appropriate physician organization, practice group and PCP information in the dropdown menus.

In the Form Type dropdown menu, select ***Patient Health Questionnaire – PHQ-9***.

Select ***Commercial*** from the Product Line dropdown menu**.**

Click ***Search Records***.

Scroll to the far right of your screen. Just above the blue header, you will see **Enter New Member**. Click on the box and a blank Patient Health Questionnaire - PHQ-9 form will appear.

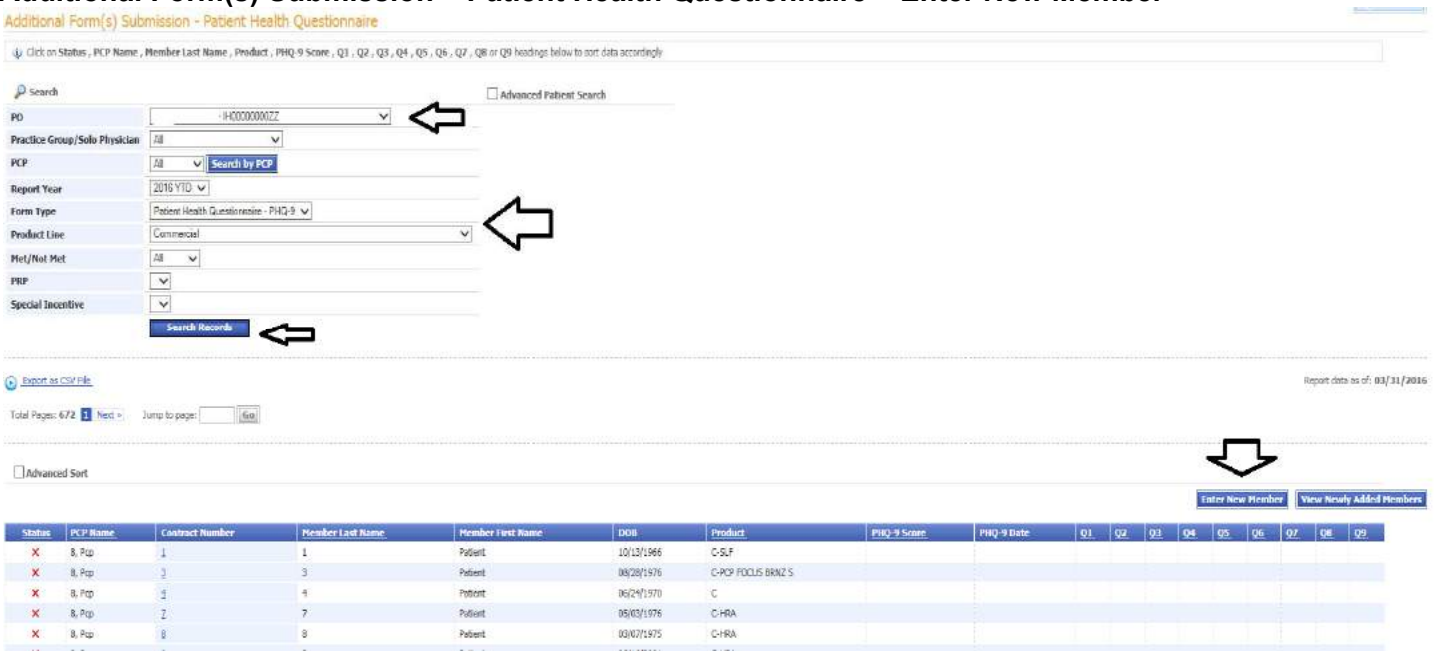
Enter the Commercial member numeric contract number that appears on the Blue Cross or BCN ID card.

Enter all demographic information for the member.

Enter the PHQ9 results.

Save and print the form for your records.

Additional Form(s) Submission – Patient Health Questionnaire – Enter New Member



Please reference the Health e-Blue homepage for the 2017 Performance Recognition Program PDF document for 2017 and 2017 Baseline and follow-up measurement periods.

2017 MHS Pay for Performance (HEDIS)

mhs

Hoosier Healthwise | Healthy Indiana Plan | Hoosier Care Connect

AGENDA

- MHS Pay For Performance (P4P)
- Secure Web Reporting
- Patient Analytics
- My Health Direct
- Question and Answer

WHAT YOU WILL LEARN

1. Measure Overviews & Specifications
2. Documentation Requirements
3. Administrative Measures
4. Secure Web Reports
5. My Health Direct
6. How Payout is Calculated

2017 P4P

- Bonus Pay for Performance (P4P) fund written into Primary Medical Provider contracts
- Measures are different for each product line
- Measures aligned with HEDIS® and NCQA
- Annual payout

2017 HOOSIER HEALTHWISE P4P

P4P SCHEDULE A-2A-1
Hoosier Healthwise

Pay-For-Performance Measures		Goal Rate	Minimum Number of Covered Persons	Points
Children's Care (Quality)				***42 points***
Childhood Immunization Status (CIS)COMBO 10	% of 2 year old Covered Persons who had the following immunizations by their second birthday: 4 DTaP, 3 IPV, 1 MMR, 3 Hib, 3 Hep B, 1 VZV, 4 PCV, 1 Hep A, 2 or 3 RV (depending on dose schedule), 2 Flu	HEDIS 75th percentile	10	7 points
Follow-Up Care for Children Prescribed ADHD Medication – Initiation Phase	% of members 6–12 years of age as of the IPSD with an ambulatory prescription dispensed for ADHD medication, who had one follow-up visit with practitioner with prescribing authority during the 30-day Initiation Phase	HEDIS 75th percentile	5	7 points
Follow-Up Care for Children Prescribed ADHD Medication – continuation phase	% of members 6–12 years of age as of the IPSD with an ambulatory prescription dispensed for ADHD medication, who remained on the medication for at least 210 days and who, in addition to the visit in the Initiation Phase, had at least two follow-up visits with a practitioner within 270 days (9 months) after the Initiation Phase ended	HEDIS 75th percentile	5	7 points
Well-Child Visits in the First 15 Months of Life (W15)	% of Covered Persons turning 15 mos within the current year who had 6 or more visits with PMP before turning 15 mos old	HEDIS 75th percentile	10	7 points
Well-Child Visits in the Third, Fourth, Fifth and Sixth Years of Life (W34)	% of Covered Persons who turned 3-6 years old within the year who had 1 or more well child visits within the current year	HEDIS 75th percentile	10	7 points
Adolescent Well-Care Visits (AWC)	% of Covered Persons 12-21 years old who had at least 1 comprehensive well care visit with PMP or OB within the current year	HEDIS 75th percentile	10	7 points

2017 HOOSIER HEALTHWISE P4P

Maternal Care (Quality)				*20 points*
Prenatal and Postpartum Care (PPC)	Timeliness of Prenatal Care - % of deliveries that received a prenatal care visit in the first trimester or within 42 days of enrollment	HEDIS 75th percentile	5	7 points
Prenatal and Postpartum Care (PPC)	Postpartum Care - % of deliveries that had a postpartum visit on or between 21 and 56 days after delivery	HEDIS 75th percentile	5	7 points
Frequency of Ongoing Prenatal Care (FPC)	81+ Percent - % of Covered Persons that received 81% or more of expected prenatal visits from time of enrollment based on ACOG recommendations	HEDIS 75th percentile	5	6 points

2017 HOOSIER HEALTHWISE P4P

Women's Care (Quality)					***7 points***
	Chlamydia Screening in Women (CHL)	% of female Covered Persons age 16-24 years identified as sexually active who had at least one Chlamydia test in the current year	HEDIS 75th percentile	5	7 points
Respiratory Care					***14 points***
	MED Management for People With Asthma (Med 75% rate)	% of members 5–64 years of age during the measurement year who were identified as having persistent asthma and were dispensed appropriate medications and remained on an asthma controller medication for at least 75% of their treatment period	HEDIS 75th percentile	5	7 points
	Asthma Medication Ratio (AMR) - total	% of members 5–64 years of age who were identified as having persistent asthma and had a ratio of controller medications to total asthma medications of 0.50 or greater during the measurement year	HEDIS 75th percentile	5	7 points
Ambulatory Measures					***7 points***
	Ambulatory Care (AMB) – ER utilization	utilization of ambulatory care in the ED - # visits per 1,000 member months	HEDIS 10th percentile	10	7 points
Provider Outreach (Administrative) Credit given for use of any 3 of the following 5:					***10 points****
	Provider-Initiated Preventive Health Outreach	Selected outreach condition must be applicable to at least 20% of total panel, i.e. telephonic campaign, Covered Person mailing campaign, special well-child health check day at your office. Report of Outreach must be received by MHS by December 31 of the measurement year. At a minimum, the outreach must be described and a list of Covered Persons who received the outreach must be included.			
	Panel Size Increase	Increase panel size by 10%			
	Training Attendance or Use of Bright Futures	Physician or Office Manager attendance in one MHS training/orientation sessions during the calendar year or documented use of the AAP Bright Futures program			
	Use of Patient Satisfaction Survey	Use of a practice-level patient satisfaction survey, such as the American Academy of Family Physicians model questionnaire			
	Use of EMR or MHS Well Visit Form	Use of Electronic Medical Record or the MHS Child or Adult Health Maintenance Form for well-visits			

*Use of 1 = 3 points
Use of 2 = 6 points
Use of 3 or more = 10 points

2017 HOOSIER HEALTHWISE P4P MEASURES

- Child and adolescent well-care
  - Childhood immunization status (CIS)
  - Well-child visits 0-15 months (W15)
  - Well-child visits 3-6 years (W34)
  - Well-adolescent visits 12-21 years (AWC)
  - Follow-up care for children prescribed ADHD medication – Acute and Continuation phases (ADD)

- Maternal care
  - Timeliness/initiation of prenatal care (PPC)
  - Frequency of prenatal care (FPC)
  - Postpartum care (PPC)

2017 HOOSIER HEALTHWISE P4P MEASURES

- Women's care
  - Chlamydia screening (CHL)

- Respiratory care
  - MED Management for Asthmatics (MMA)
  - Asthma Medication Ratio (AMR) - total

- Ambulatory Measures
  - Ambulatory Care (AMB) – ER utilization

2017 HIP P4P

P4P SCHEDULE A-2B-1
Healthy Indiana Plan (HIP)

Pay-For-Performance Measures			Goal Rate	Minimum Number of Covered Persons	Points
Women's Care (Quality)					***21 points***
	Chlamydia Screening in Women (CHL)	% of female Covered Persons age 16-24 years identified as sexually active who had at least one Chlamydia test in the current year	HEDIS 75th percentile	5	7 points
	Cervical Cancer Screening (CCS)	% of female Covered Persons age 24-64 years who received 1 or more Pap tests to screen for cervical cancer in the current year	HEDIS 75th percentile	5	7 points
	Breast Cancer Screening (BCS)	% of women 50–74 years of age who had a mammogram to screen for breast cancer	HEDIS 75th percentile	5	7 points
Maternal Care (Quality)					***20 points***
	Prenatal and Postpartum Care (PPC)	Timeliness of Prenatal Care - % of deliveries that received a prenatal care visit in the first trimester or within 42 days of enrollment	HEDIS 75th percentile	5	7 points
	Prenatal and Postpartum Care (PPC)	Postpartum Care - % of deliveries that had a postpartum visit on or between 21 and 56 days after delivery	HEDIS 75th percentile	5	7 points
	Frequency of Ongoing Prenatal Care (FPC)	81+ Percent - % of Covered Persons that received 81% or more of expected prenatal visits from time of enrollment based on ACOG recommendations	HEDIS 75th percentile	5	6 points

2017 HIP P4P

Respiratory Care					***14 points***
	MED Management for People With Asthma (Med 75% rate)	% of members 5–64 years of age during the measurement year who were identified as having persistent asthma and were dispensed appropriate medications and remained on an asthma controller medication for at least 75% of their treatment period	HEDIS 75th percentile	5	7 points
	Pharmacotherapy Management of COPD Exacerbation (PCE) - systemic corticosteroid	% of COPD exacerbations for members 40 years of age and older who had an acute inpatient discharge or ED visit on or between January 1–November 30 of the measurement year and who were dispensed a systemic corticosteroid (or there was evidence of an active prescription) within 14 days of the event	HEDIS 75th percentile	5	7 points

2017 HIP P4P

Behavior Health Care					***7 points***
	Antidepressant Medication Management (AMM) – Acute Phase	% of members who remained on an antidepressant medication for at least 84 days (12 weeks)	HEDIS 75th percentile	5	7 points
Diabetes Care					***14 points***
	Diabetes Care - Eye exam (retinal) performed	% of members 18–75 years of age with diabetes (type 1 and type 2) who had an eye exam (retinal) performed	HEDIS 75th percentile	5	7 points
	Diabetes Care - Medical attention for nephropathy	% of members 18–75 years of age with diabetes (type 1 and type 2) who had medical attention for nephropathy	HEDIS 75th percentile	5	7 points
Ambulatory Measures					***14 points***
	Ambulatory Care (AMB) – ER utilization	utilization of ambulatory care in the ED - # visits per 1,000 member months	HEDIS 10th percentile	10	7 points
	Adults' Access to Preventive/Ambulatory Health Services (AAP)	% of members 20 years and older who had an ambulatory or preventive care visit	HEDIS 75th percentile	10	7 points
Provider Outreach (Administrative) Credit given for use of any 3 of the following 5:					***10 points****
	Provider-Initiated Preventive Health Outreach	Selected outreach condition must be applicable to at least 20% of total panel, i.e. telephonic campaign, Covered Person mailing campaign, special well-child health check day at your office. Report of Outreach must be received by MHS by December 31 of the measurement year. At a minimum, the outreach must be described and a list of Covered Persons who received the outreach must be included.			
	Panel Size Increase	Increase panel size by 10%			
	Training Attendance or Use of Bright Futures	Physician or Office Manager attendance in one MHS training/orientation session during the calendar year or documented use of the AAP Bright Futures program			
	Use of Patient Satisfaction Survey	Use of a practice-level patient satisfaction survey, such as the American Academy of Family Physicians model questionnaire			
	Use of EMR or MHS Well Visit Form	Use of Electronic Medical Record or the MHS Adolescent or Adult Health Maintenance Form for well-visits			
	P4P Scoring Key for Provider Outreach • Complete one activity above to earn 3 Points. (30% payment for this section) • Complete two activities above to earn 6 Points. (60% payment for this section) • Complete three or more activities above and earn 100% payment for this section.				

2017 HIP P4P Measures

- Maternal care
  - Timeliness/initiation of prenatal care (PPC)
  - Frequency of prenatal care (FPC)
  - Postpartum care (PPC)

- Women's Care
  - Chlamydia Screening (CHL)
  - Cervical Cancer Screening (CCS)

Patient Analytics

What is Patient Analytics?

- Patient Analytics is a web-based patient care platform that uses claims data to create a detailed patient- and population-level reporting

Patient Analytics

Why Was Patient Analytics Created?

- Patient Analytics was created to enable providers to make more informed patient care decisions based on health histories, current diagnoses, and prescription regimens, which also supports population health views and outreach initiatives

Patient Analytics

What Does Patient Analytics Do?

- Within Patient Analytics, each patient has a detailed clinical profile. Patients with the most care gaps are identified allowing providers to take a proactive approach to managed care

Key Benefits

- **Population Health:** Providers are able to manage member's information using patient registries. The information can easily be accessed online and many elements can be printed
- **Medical History** – Patient Analytics contains up to 24 months of medical, pharmacy, and lab claims
- **Increased Visibility** – Primary Care Physicians (PCPs) will have access to claims history submitted by other providers
- **Improved Outcomes:** Patient Analytics helps providers improve patient care, performance, outcomes and adherence to quality measures

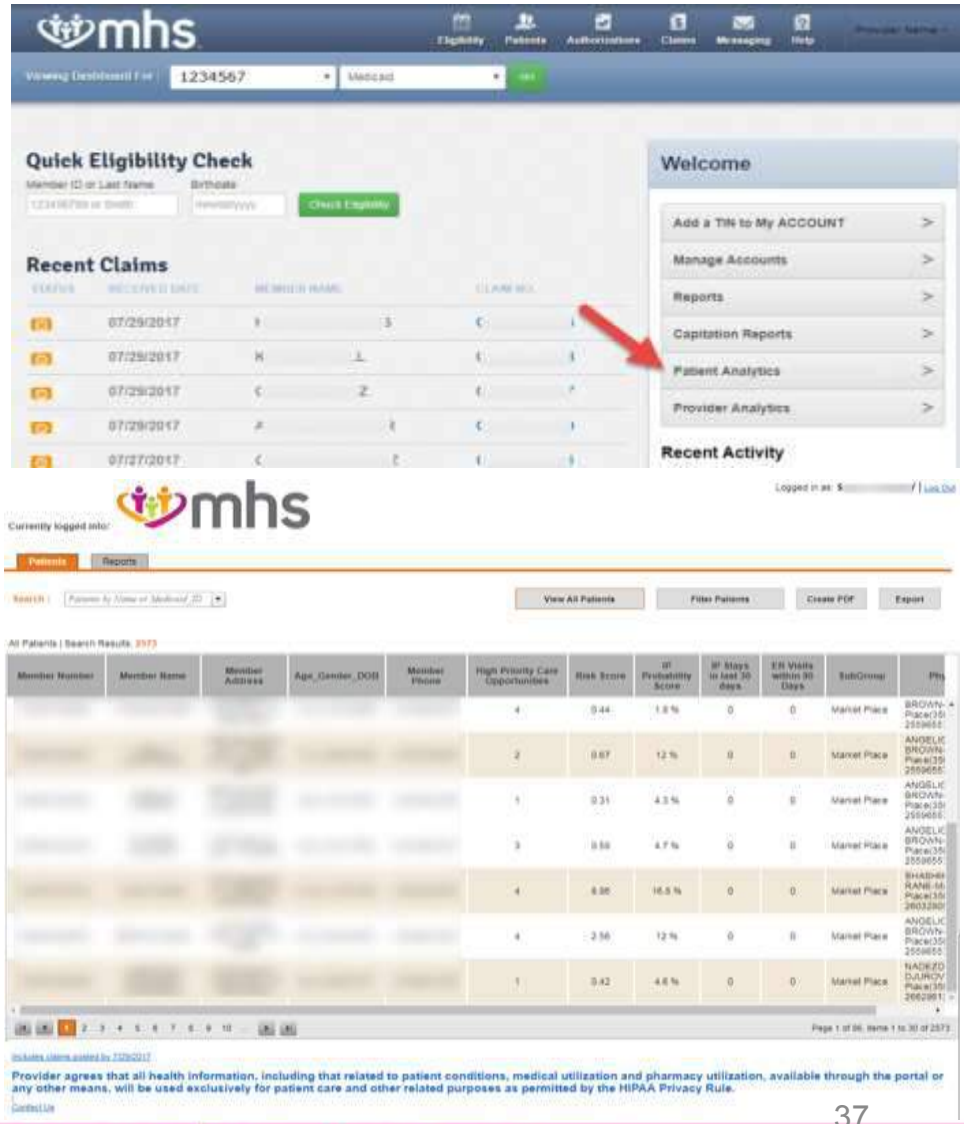
Accessing Patient Analytics

- When logging into Patient Analytics, the user is presented with the Patients tab as the main landing page. Across the top of the screen are the following buttons:

- View All Patients – This button will remove any filter options and display all patients for which the user has access
- Filter Patients – By selecting this button, an info window generates allowing the user to select patients that fit a specific criteria

  Manage Filters: Filter the patient list by business rules, subgroups, and physicians.

- Create PDF – Generate a .pdf document or printer friendly version of the patient list
- Export – Exports the Patient List to an Excel worksheet



Patients Tab

1. **Tabs:** Allows the providers to choose between the Patients information and Reports
2. **Logout Button:** For security purposes, logout to protect patient information. Not shown, in upper right hand corner
3. **Search:** Allows providers to search by the patient's name, Medicaid, Medicare or Marketplace ID number
4. **Filters and Export Features:** Allows users to view all patients or filter by multiple criteria. The users will also have the ability to create a PDF document or export a detailed patient profile

    4a. Manage Filters: Filter the patient list by business rules, subgroups, and physicians

5. **Timeframe:** Provides the date when claims have been posted, followed by a link to contact for questions or concerns

Patient Demographics

All Patients | Search Results: 3089

Member Number	Member Name	Member Address	Age_Gender_DOB	Member Phone	High Priority Care Opportunities	Risk Score	IP Probability Score	IP Stays in last 30 days	ER Visits within 90 Days	SubGroup	Phy

High Priority Care Opportunities: Displays a count of care opportunities deemed to be of the highest importance

Risk Score: Identifies the likelihood that the patient will incur cost and services in the next 12 months when compared to an average patient. An average patient has a health of 1.0. Higher values indicate the patient is more likely to need services in the future

IP Probability: A percentage indicating the likelihood that a patient will have one or more inpatient confinements in the next 12 months

Inpatient Stays in the Last 30 Days: A metric that captures the number of distinct inpatient hospitalizations in the last 30 days based on processed claims

Emergency Room Visits within 90 Days: A metric that shows the number of distinct emergency room visits within 90 days based on processed claims

Subgroup: Medicaid, Medicare, or Marketplace

Physician: Displays the provider's name and credentials

Patient Profile

1. **Member Demographics:** Displays information about the member
2. **All Care Opportunities**: The default landing page for patient details. Displays care opportunities or measures that indicate if a patient has or has not received treatment for a health condition
3. **Diagnosis:** Shows primary and secondary diagnoses from claims data
4. **Procedures:** Shows patient procedures associated with primary and secondary diagnoses
5. **Medications:** Displays a list of medications prescribed to the patient
6. **Lab/Observational:** Shows lab values, interpretations, and trends
7. **Care Team:** Allows users to view the patient's providers. Providers are labeled as Managing Doctor or Other Doctor

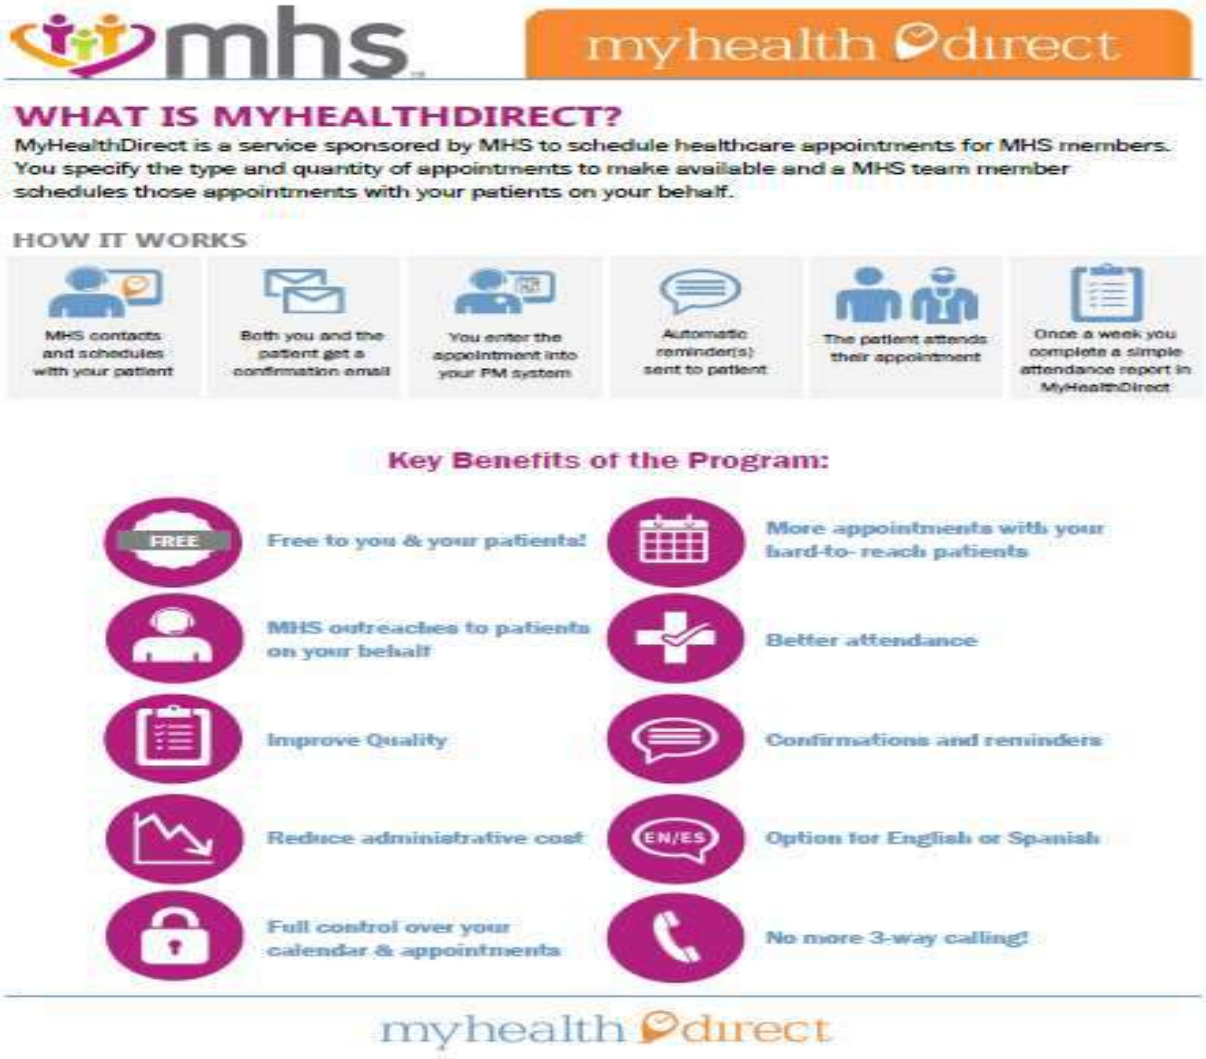
MYHEALTHDIRECT



mhs

FREQUENTLY ASKED QUESTIONS

1 How do I get started?

One time:

1. Complete the Clinic Setup Form and User Agreements
2. Activate your user account
3. Schedule and complete the training webinar (est. 45 minutes)

Ongoing Responsibilities:

1. Enter appointments promptly as you receive the confirmations
2. Report attendance weekly
3. Keep your calendar up to date

2 How do I keep from double booking?

You always have full control over your calendar. You make appointments available in MyHealthDirect and then block them in your practice management system. When an appointment comes in through MyHealthDirect, you enter the information and change the blocked slot to a scheduled appointment. If you want to schedule an appointment for a blocked slot, it's easy to remove that slot from your MyHealthDirect inventory so it isn't double-booked.

3 I don't want appointments to go unused

All appointments have a give-back rule known as a "restriction." We recommend setting your appointment restrictions at 72 hours. If an appointment is still unbooked 72 hours out, it will automatically become unavailable in MyHealthDirect and your staff can fill it without concern for double-booking.

4 Can I get appointment confirmations other ways?

Confirmation emails can be sent by email, fax, or both. Additionally, a connector is available for practices with a high volume of appointments. This connector allows MyHealthDirect to update your practice management system directly. Please contact your MyHealthDirect Account Executive for more information.

More Questions? *Please feel free to contact your Provider Representative or MyHealthDirect at any time!*

Questions

Thank you for partnering with MHS

Increasing Awareness and Uptake of Influenza Immunization

Glen Nowak, Ph.D.
Acting Director of Media Relations, CDC
Associate Director for Communications, NIP/CDC

"Warning"

- Good (i.e., effective) communication is a necessary but usually only partially sufficient condition for achieving desired behaviors.
- Facts, figures, and statistics, in and of themselves, don't equate to good communication (nor does more information equal good communication).

Question

"It strikes 2 million Americans each year. And complications from this kill up to 200,000 people a year--more people than breast cancer, car crashes, and AIDS combined. The good news is, in most cases, this can be prevented."

What is it that causes this harm? (And does having this information change your behavior?)

IntelligenceReport®

By Lyric Wallwork Winik

Stop A Deadly Killer

Skater Tara Lipinski suffered from DVT.

It strikes 2 million Americans each year and kills more people than breast cancer, car crashes and AIDS combined, yet most of us do not even know its name. The condition is called deep vein thrombosis, or DVT. It begins with a blood clot in the leg that can travel to the lungs, causing a pulmonary embolism and often death. Many of us are at risk—just sitting for a long time on a plane can produce DVT. But older people, pregnant women, smokers, the obese and others with a condition that limits mobility are at increased risk. Symptoms include leg tenderness, pain, swelling, discoloration or redness. If you suspect DVT, call a doctor immediately: There are quick, noninvasive tests to identify it, plus options ranging from blood thinners to simple exercises. National DVT Awareness Month begins tomorrow. Go to www.preventdvt.org to learn more.

A magnetic scan shows a leg blockage (white line), indicating deep vein thrombosis. Its clots can be fatal.

There are tests to identify DVT, and simple solutions.

SAFER • HEALTHIER • PEOPLE™

"Recipe" for Fostering Public Interest and High Vaccine Demand (1)

1. Influenza's arrival coincides with immunization "season" (i.e., when people can take action)
2. Dominant strain and/or initial cases of disease are:
   - Associated with severe illness and/or outcomes
   - Occur among people for whom influenza is not generally perceived to cause serious complications (e.g., children, healthy adults, healthy seniors)
   - In cities and communities with significant media outlets (e.g., daily newspapers, major TV stations)

"Recipe" for Fostering Public Interest and High Vaccine Demand (2)

3. Medical experts and public health authorities publicly (e.g., via media) state concern and alarm (and predict dire outcomes)– and urge influenza vaccination.
4. The combination of '2' and '3' result in:
   A. Significant media interest and attention
   B. Framing of the flu season in terms that motivate behavior (e.g., as "very severe," "more severe than last or past years," "deadly")

"Recipe" for Fostering Public Interest and High Vaccine Demand (3)

5. Continued reports (e.g., from health officials and media) that influenza is causing severe illness and/or affecting lots of people– helping foster the perception that many people are susceptible to a bad case of influenza.
6. Visible/tangible examples of the seriousness of the illness (e.g., pictures of children, families of those affected coming forward) and people getting vaccinated (the first to motivate, the latter to reinforce)
7. References to, and discussions, of pandemic influenza– along with continued reference to the importance of vaccination.

Implications of the "Recipe"

- A large component of consumer demand for flu vaccination is contingent upon things we can't control (e.g., timing, severity, extent, duration of the disease and resulting illness).
- Fostering demand, particularly among people who don't routinely receive an annual influenza vaccination, requires creating concern, anxiety, and worry. For example:
  - A perception or sense that many people are falling ill;
  - A perception or sense that many people are experiencing bad illness;
  - A perception or sense of vulnerability to contracting and experiencing bad illness.

Additional (Pandemic) Influenza Communication Challenges

- Recommendations and perceptions regarding influenza vaccination are not "universal" (and achieving consensus by "fiat" is difficult)
- "Mass media" doesn't effectively reach "the mass"
- Mixed messages and advice are hard to avoid

Influenza Immunization Recommendations and Perceptions

- Until recently, influenza vaccination recommended primarily for 65 and older and people with certain chronic medical conditions– fostering perception that vaccination was for "elderly" and "frail"
- Now recommended for 50-64 year olds and 6-23 month olds– to many, implying a) its helpful primarily for older people and b) we have data that supports such precision
- Experts "nuance" recommendations, but the public (as well as many healthcare providers) don't similarly nuance their perceptions (e.g., "recommend" vs. "encourage," 6-23 month olds vs. 2 year olds)

Three Likely Population Segments

- **People who routinely receive an annual influenza vaccination, including those we recommend do so**
  - Primarily 65 years old and older
  - Primarily get vaccinated in Sept-November
- **People who sometimes receive an annual influenza vaccination, including those we recommend do so**
  - Interest is often contingent on perceptions of severity of the strain, likelihood they or someone they know will contract it, their belief they will experience or transmit a severe case
  - Appear to get vaccinated later (November, early December)
- **People who choose not to get an influenza vaccination, including those we recommend do so:**
  - Inversely related to age (e.g., most likely 18-49)
  - Among older people, often based on a firmly held belief/conviction

"Mass Media" Less Helpful

- Most people have 10 or so options when it comes to television viewing– many have 50-100 or more
- Hundreds of websites offer medical and health information
- Daily newspaper readership has been declining, particularly among 18-49 year olds
- Cultural and ethnic diversity is greater than ever
- Health literacy is a growing problem
- Belief that today you need to expose people to your message 10-12 times to achieve attention

The Challenge of Avoiding "Mixed Messages and Advice"

- Often arise when expert actions and behaviors don't seem to match or be consistent with policies and recommendations (e.g., healthcare providers not getting annual influenza vaccinations)
- Often fostered by a desire to improve our ability to provide services should large numbers of people act upon our advice
- Often recognized primarily in hindsight– and in contexts outside our own area of expertise

Tom Toles

Washington Post May 2004

Tom Toles ***(Modified)***

Washington Post May 2004

Some Recommendations

- Adopt more sophisticated approach to influenza-related communication:
  - Greater investment in communication research
  - Greater appreciation of need for a) less nuanced messages/advice and b) development/use of a portfolio of messages and materials
  - Plans that extend beyond news media reliance
- Recognition that the kind of communication activities envisioned (e.g., broad scope, high visibility, message frequency) require significant investment
- Greater understanding and use of risk communication principles (e.g., dilemma sharing, acknowledging uncertainty, providing coping strategies and advice)

Thank You

Global Vaccine Market Features and Trends

Miloud Kaddar

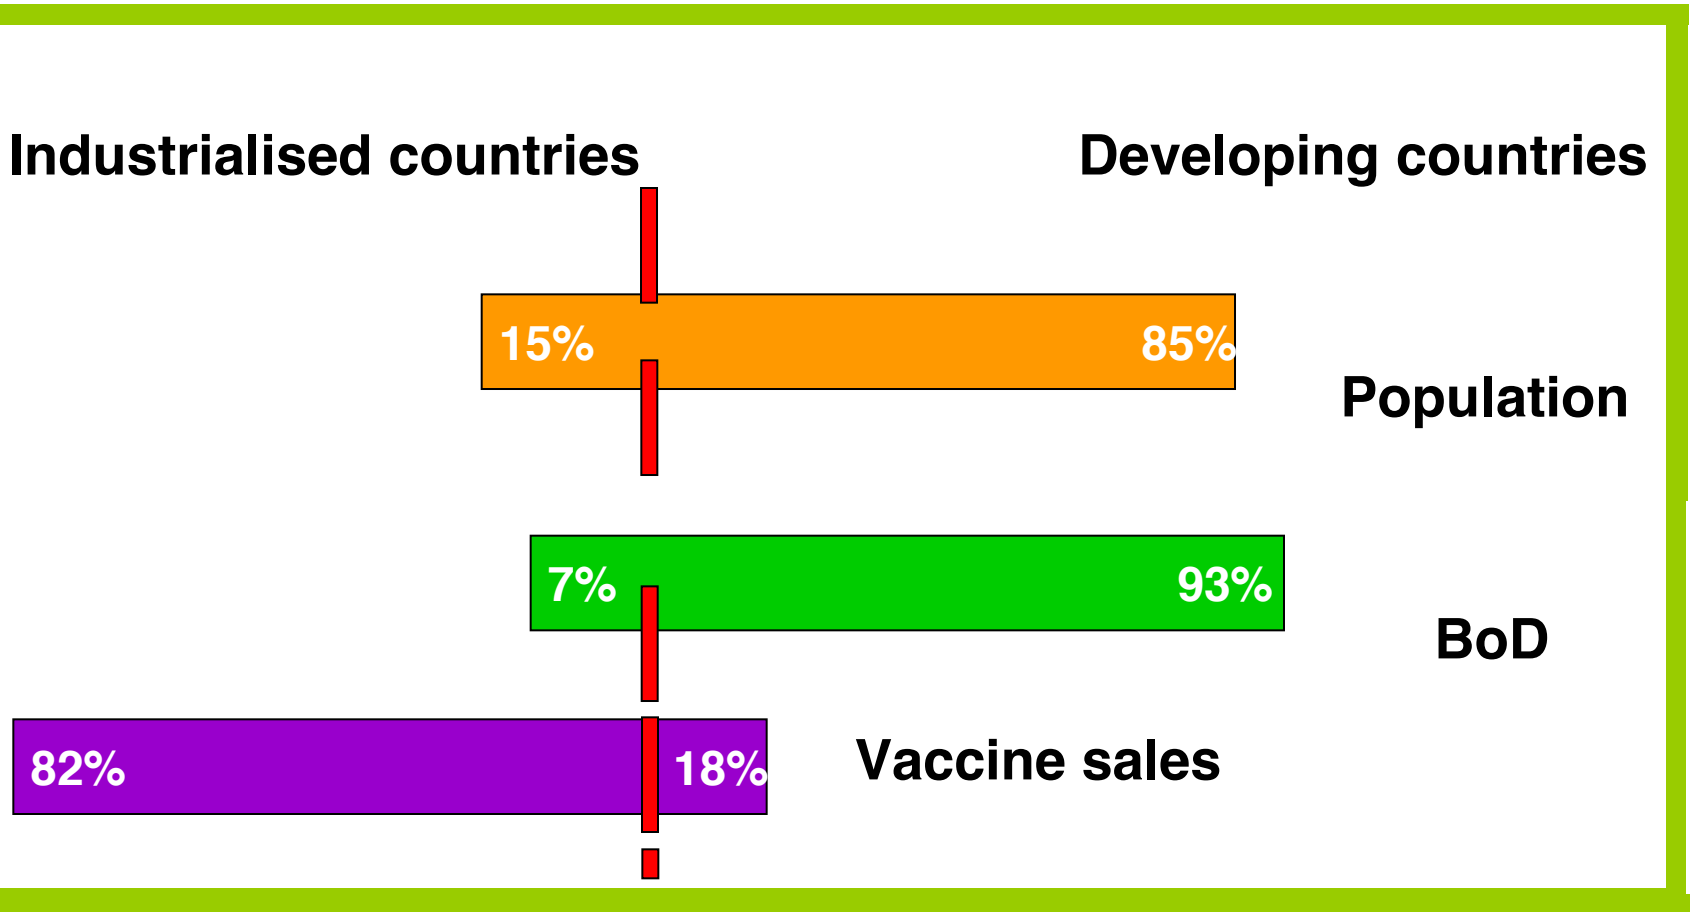
Senior Adviser, Health Economist

WHO, IVB, Geneva

GLOBAL VACCINE MARKET

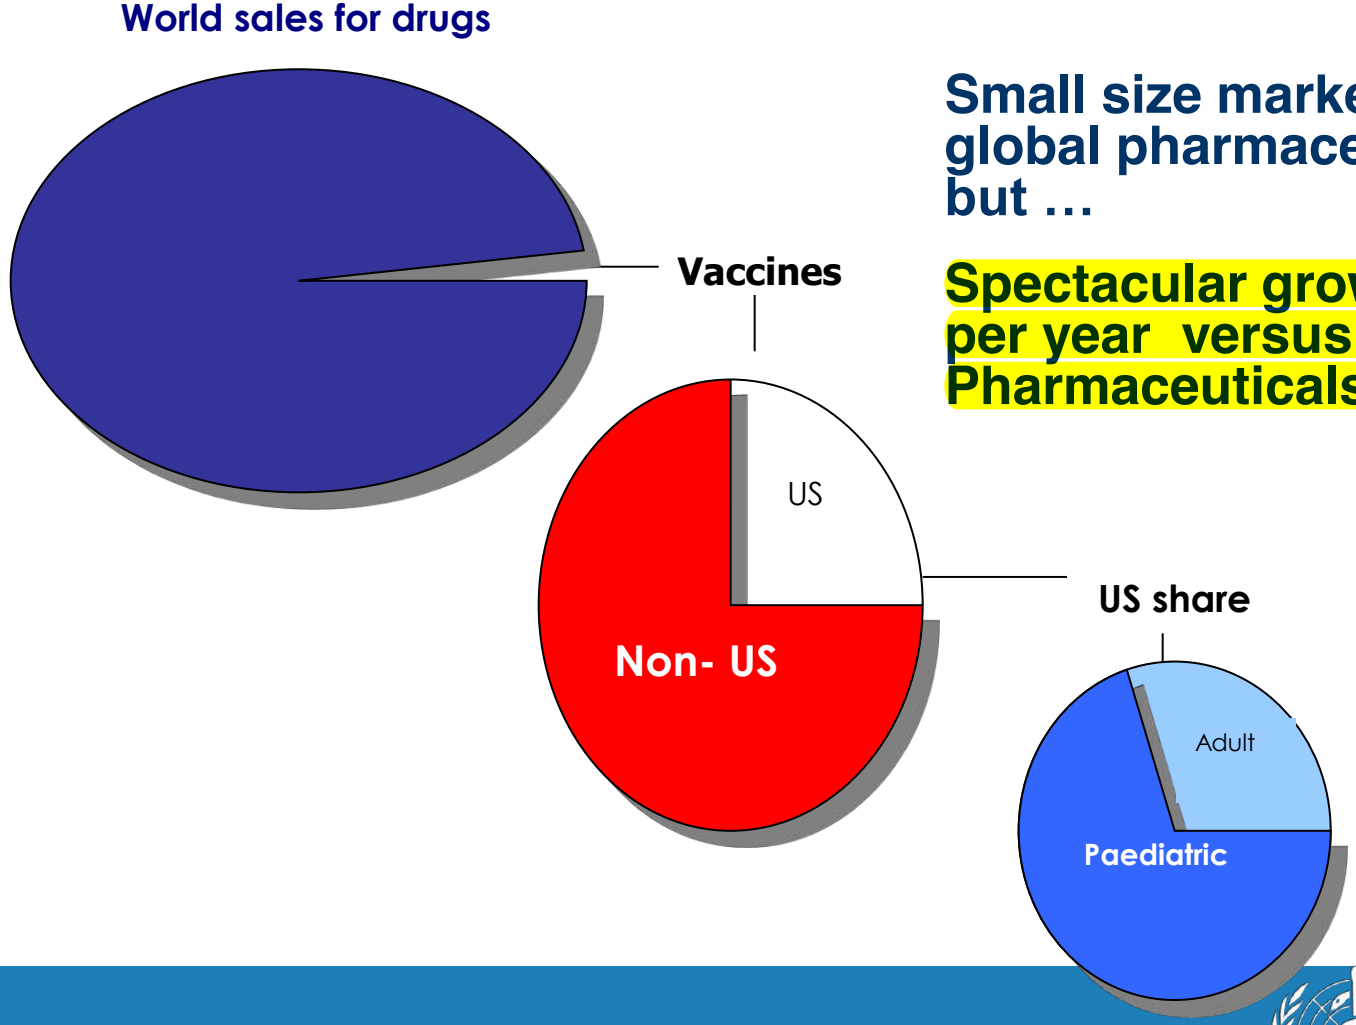
- MAIN FEATURES OF THE VACCINE MARKET ?
- NEW TRENDS SINCE 2000 ?
- IMPLICATIONS ?

Vaccine Market
North – South GAP



World Health Organization

VACCINE MARKET STRUCTURE 2010

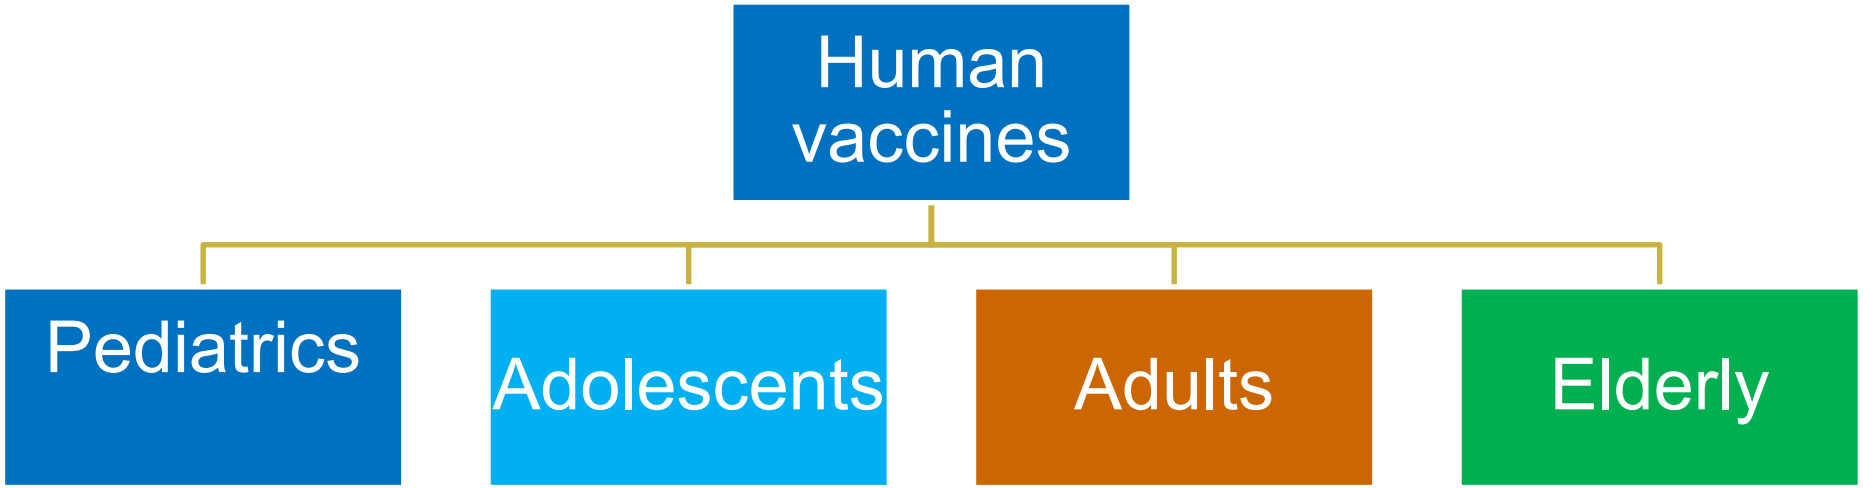


Small size market : 2/3% of the global pharmaceutical market but …

Spectacular growth rate : 10 - 15% per year versus 5-7 % for Pharmaceuticals

World Health Organization

Vaccine segments



World Health Organization

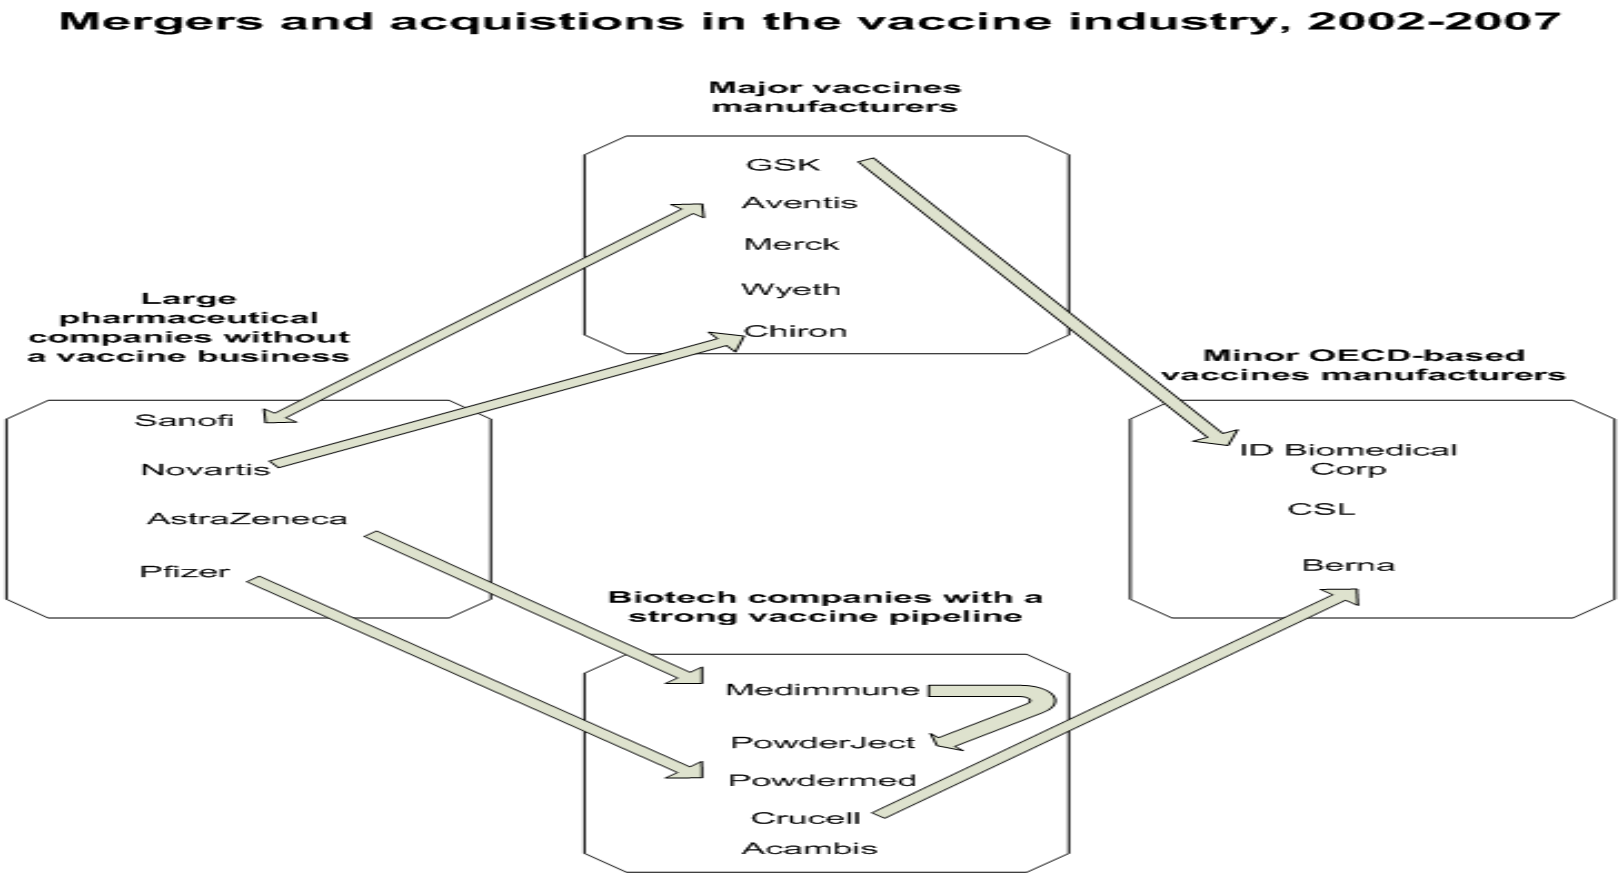
GLOBAL VACCINE MARKET: RAPID GROWTH and CHANGING STATUS

- Tripled in value from USD 5B in 2000 to almost USD 24 B in 2013
  - Influenza vaccine market: estimated at $2.9 billion in 2011 to $3.8 billion by 2018
  - US : $1.6 billion in 2011 to $2.2 billion in 2018
- Global market projected to rise to USD 100 B by 2025
- More than 120 new products in the development pipeline
- 60 are of importance for developing countries
- Vaccines: becoming an engine for the pharmaceutical industry
- Changing status of the vaccines within the pharmaceutical industry
- New business model for vaccines is emerging?

Main features of Vaccine market (2)

- Newer and more expensive vaccines are coming into the market faster than ever before
- Growing concentration in OECD countries but also newcomers (Pfizer, J&J,..)
- Vaccine development: increasing investment

MERGERS AND ACQUISITIONS 2002-2007: Illustration



Note. Double arrows denote mergers, single arrows denote acquisitions where the origin of the arrow is the buyer. Headings (such 'large pharmaceutical companies without a vaccine business') and company names refer to the situation in 2002.

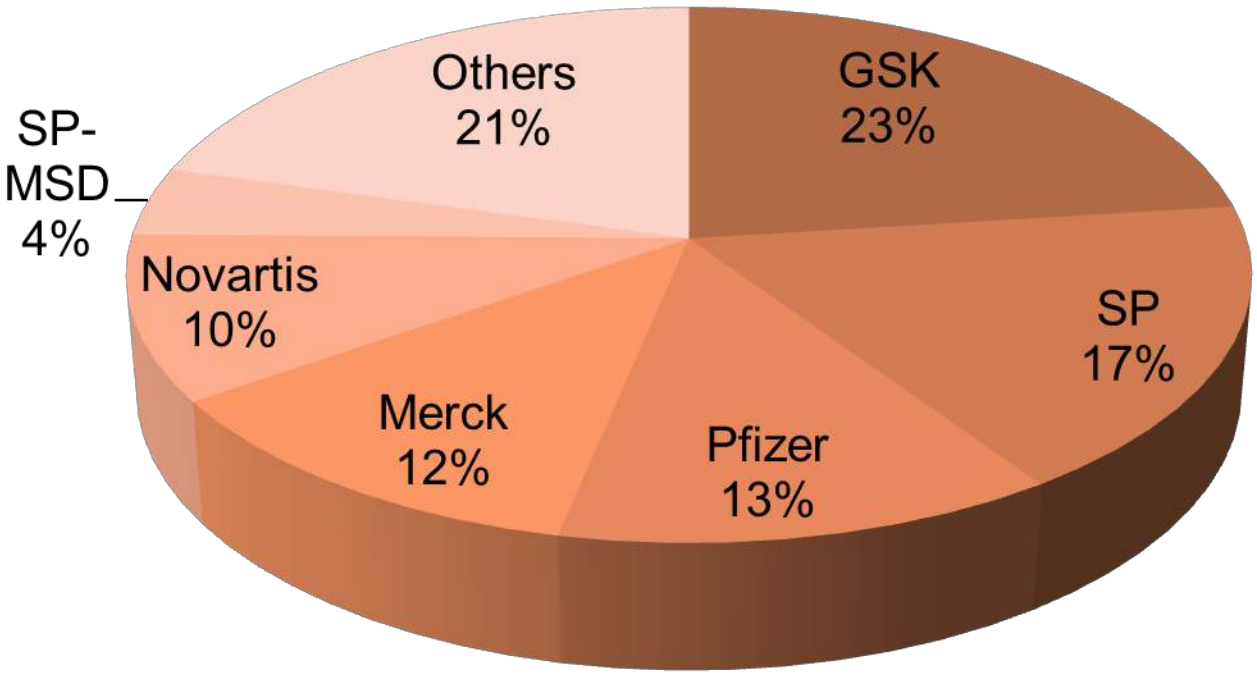
World Health Organization

Overview of major vaccine related acquisitions (2005-2012)

Target Company	Acquiring Company	Investment Made	Date Announced
1.Bilthoven Bio of Netherlands	Serum Institute of India Ltd	Euros 80M	July 2012
2.Zhejiang Tianyuan Bio	Novartis	$ 125 M?	March 2011
3.Wyeth	Pfizer	$68 bn	Jan 2009
4.MedImmune	AstraZenecea	$15.6 bn	April 2007
5.Chiron	Novartis	$5.1 bn	Oct 2005
6.Crucell	Johnson & Johnson	$2.6 bn	Sep 2009
7. ID Biomedical	GSK	$1.4 bn	Sep 2005
8.Shantha Bio	Sanofi Aventis	$781 mn	July 2009
9.Acambis	Sanofi Aventis	$549 mn	July 2008
10. Intercell	Novartis	$363 mn	July 2007
11. Corixa	GSK	$300 mn	May 2005
12. PowderMed	Pfizer	$230 mn	Oct 2006
13. Coley	Pfizer	$214 mn	Nov 2007

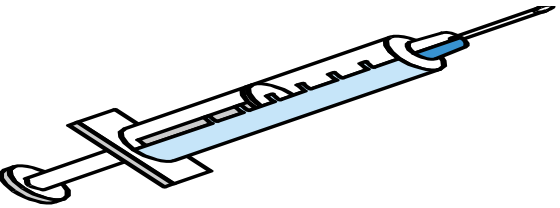
Source:VacZine Analytics + Fierce vaccine

Global vaccine leaders



- 5 large multi-national corporations make up 80% of the global market
- Major focus on new vaccine development for industrialised country markets

World Health Organization



Top product sales in 2010

Brand name (producer)	Type/composition	2010 sales (US$)
Prevnar-13 (Pfizer)	13-valent pnenumococcal conjugate vaccine	$2.4 billion
Proquad (Merck/Sanofi-Aventis)	Measles-mumps-rubella and varicella combination vaccine (MMR-V)	$1.4 billion
Gardasil (Merck)	HPV	$1.35 billion
Prevnar (Pfizer)	7-valent pnenumococcal conjugate vaccine	$1.2 billion
Fluzone (Sanofi Pasteur)	Influenza (seasonal and H1N1 strains)	$1.2 billion
Infanrix and Pediarix) (GSK)	Infanrix = DTaP Pediarix = DTap-HepB-IPV (combination DPT-based vaccines with acellular pertussis)	$1.2 billion

Source: Krishan Maggon knoll (http://knol.google.com/k/krishan-maggon/global-vaccine-market-2010/3fy5eowy8suq3/152….)

Total sales First half 2012

	Vaccine	Company	H1 Sales	Use
1	Prevnar 13	Pfizer	$1.847 billion	Pneumococcal infection
2	PENTAct-HIB	Sanofi	$672 million	Diphtheria, Pertussis/whooping cough; Tetanus; Polio; Haemophilus influenza type b
3	Gardasil	Merck & Co	$608 million	human papillomavirus (HPV)
4	Pediarix	GlaxoSmithKline	$535 million	Diphtheria; Tetanus; Pertussis/whooping cough; Hepatitis B; Polio
5	Hepatitis Vaccine Franchise	GlaxoSmithKline	$500 million	Hepatitis A; Hepatitis B
6	Celtura	Novartis	$441 million	Swine flu
7	Varivax	Merck & Co.	$392 million	Varicella virus
8	Cervarix	GlaxoSmithKline	$285 million	HPV
9	RotaTeq	Merck & Co.	$284 million	Rotaviral gastroenteritis
10	Synflorix	GlaxoSmithKline	$274 million	Pneumococcal infection; Otitis media
11	Rotarix	GlaxoSmithKline	$266 million	Rotaviral gastroenteritis

Total sales First half 2012 (2)

	Vaccine	Company	H1 Sales	Use
12	Zostavax	Merck & Co.	$224 million	Shingles; Herpes
13	Prevnar 7	Pfizer	$222 million	Pneumococcal infection; Otitis media
14	Fluzone/Vaxigrip	Sanofi	$219 million	Influenza
15	Menactra	Sanofi	$217 million	Meningitis
16	Pneumovax	Merck & Co.	$213 million	Pneumococcal infection
17	Adacel	Sanofi	$207 million	Diphtheria; Pertussis/whooping cough; Tetanus
18	MMR-II	Merck & Co.	$180 million	Measles, Mumps, Rubella
19	Boostrix	GlaxoSmithKline	$165 million	Diphtheria; Tetanus; Pertussis/whooping cough
20	Biothrax	Emergent BioSolutions	$88 million	Anthrax

Sources: EvaluatePharma; Fiercevaccines, Sep 2012

VACCINE MARKET : GROWTH FACTORS ?

Combination of :

- Importance of communicable diseases and new threats
- Cost effectiveness of immunizations
- New funding opportunities (Gov, PPP, donors, Foundations,..)
- New research techniques and manufacturing technologies
- Increasing demand, new target population, larger emerging markets
- Higher prices, improved profitability for the industry (blockbuster vaccines..)

Developing countries: vaccine market share and trends

Developing country market

80 % of population / less than 20% of global market

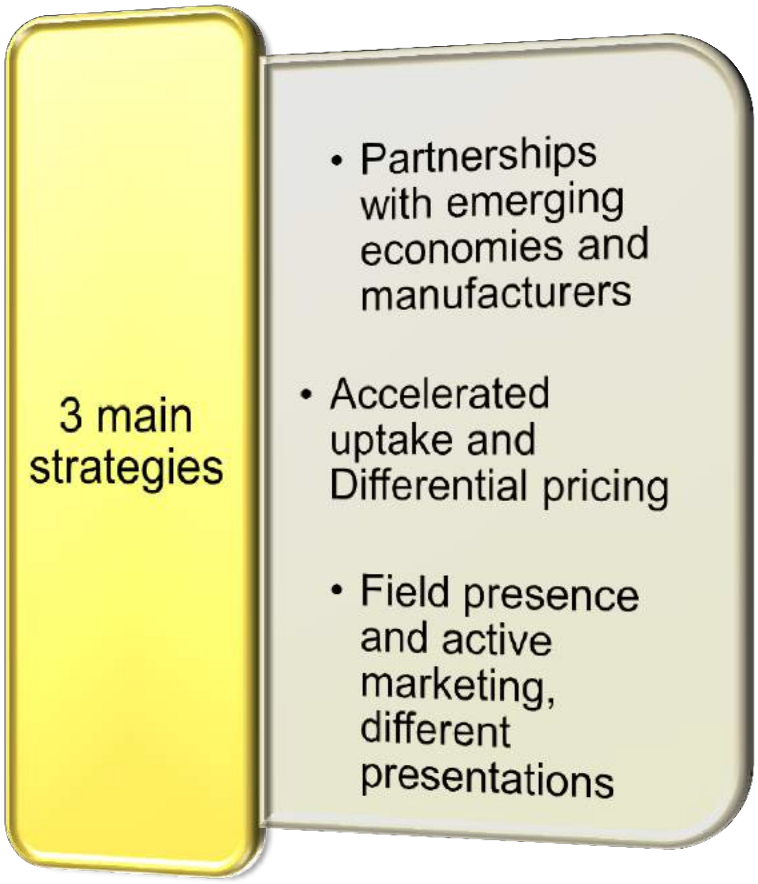
Regular and rapid growth in volume and dollar value

Emerging economies and markets	UN market	Private sector in Low and Middle income countries

MNC : Key strategies for developing countries

3 main targets:

- Emerging economies
- UN markets (UNICEF/GAVI and PAHO)
- Private sector, middle income group markets



World Health Organization

Arrangements with emerging economies and manufacturers

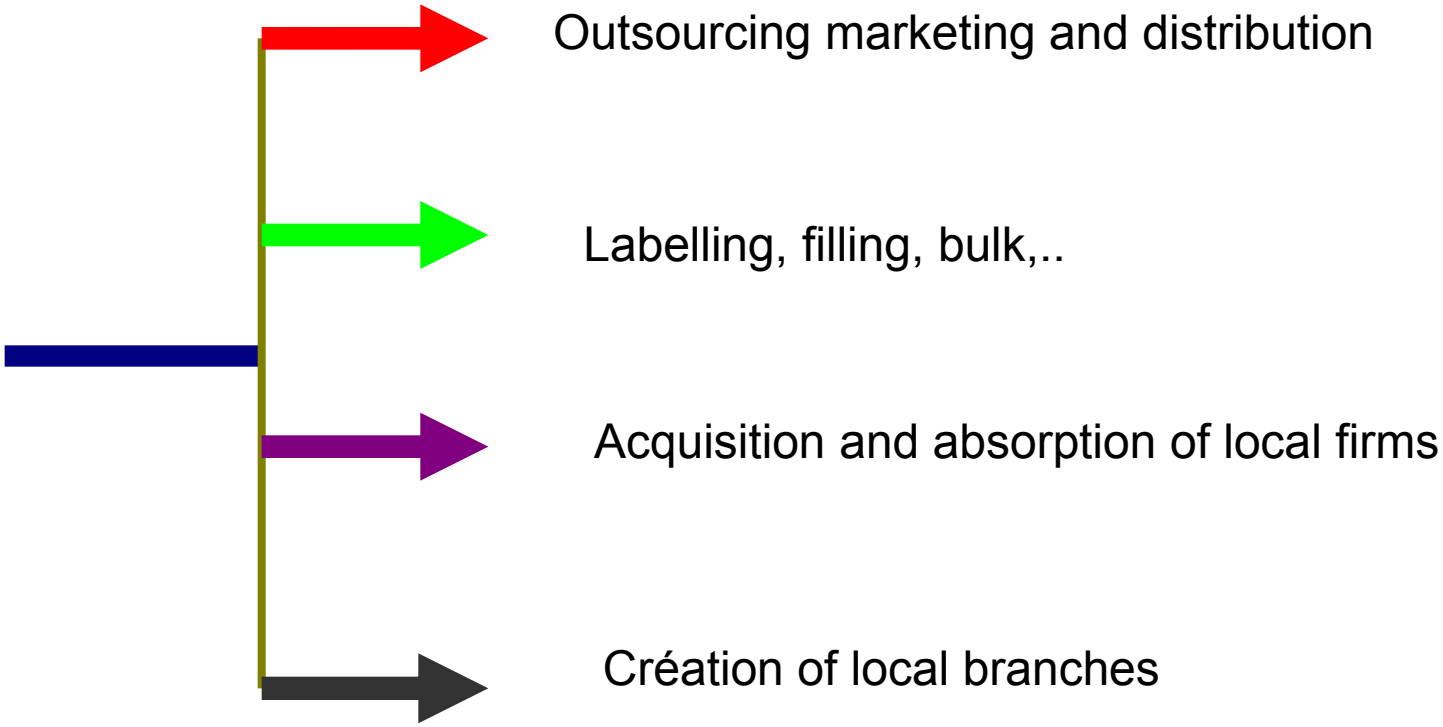
- Various types of arrangments, contracts and partnerships

- Taking into account country potentials and particularities:
  - size of population and potential market,
  - legislation favouring or not domestic production and TT,
  - production costs, scientific and technical capacity, price regulation,
  - NIP, immunization in the private sector,
  - regional influence,..

- Directly with countries and local manufacturers or through PPP or PDP

Various types of arrangements

Objectives:
lower costs, increase production capacity, competitive position
access to large public and private market, …



A new trend: more active vaccine marketing in DC

- Emerging markets such as Mexico, Brazil, Turkey, Indonesia, Russia, China and India are among key priorities for MNC
- Singapour, Malaysia, Vietnam, Philippines, Egypt, GCC and others: second line
- Wide licensing and registration of new and innovative vaccines
- Increased presence of sale forces and MNC representatives : "pharma like model"

MNC = Multinational Corporation

New business MNC model is emerging?

- More mapping, market segmentation and price differentiation
- Outsourcing selected part of R&D, production and commercialization/Access to promising markets and local capacities, low costs
- Risk sharing with countries and funders
- Collaborative networks and active presence at GHIs

UN Market: UNICEF and PAHO

Spectacular increase in the last 10 years

Both UNICEF SD and PAHO

Polio, measles, new vaccines

National, regional and global priority

MDGs, GIVS, GAVI, AMC, IFFim, GPEI, Measles partnership, BMGF, DOV/GVAP

World Health Organization

UN MARKET (in value)

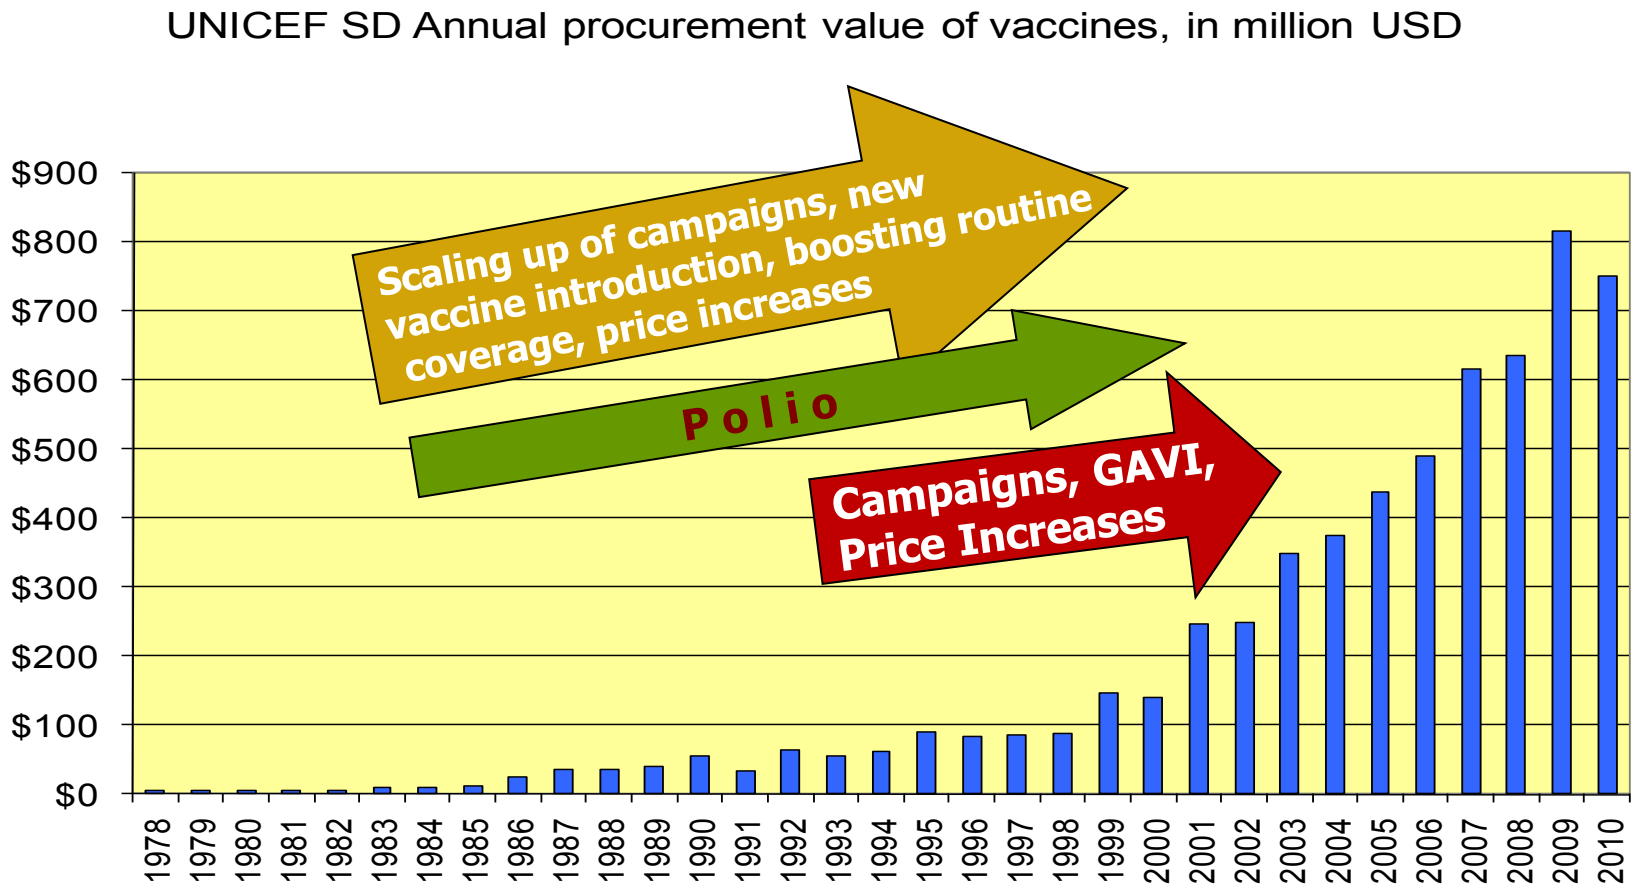
	2002	2011	%
UNICEF SD	$ 220 million	$ 1,03 Billion	+ 468%
PAHO RF	$ 120 million	$ 400 million	+ 333%
Total	$ 340 million	$1,430 billion	+ 420%

Around 7, 5 % of total vaccine sales

Sources: our WHO estimates based on UNICEF SD and PAHO RF data

World Health Organization

UNICEF annual vaccine procurement has increased five fold since 2000 - supporting UNICEF Programmes and on behalf of Partners, Global Programmes Governments and NGO's

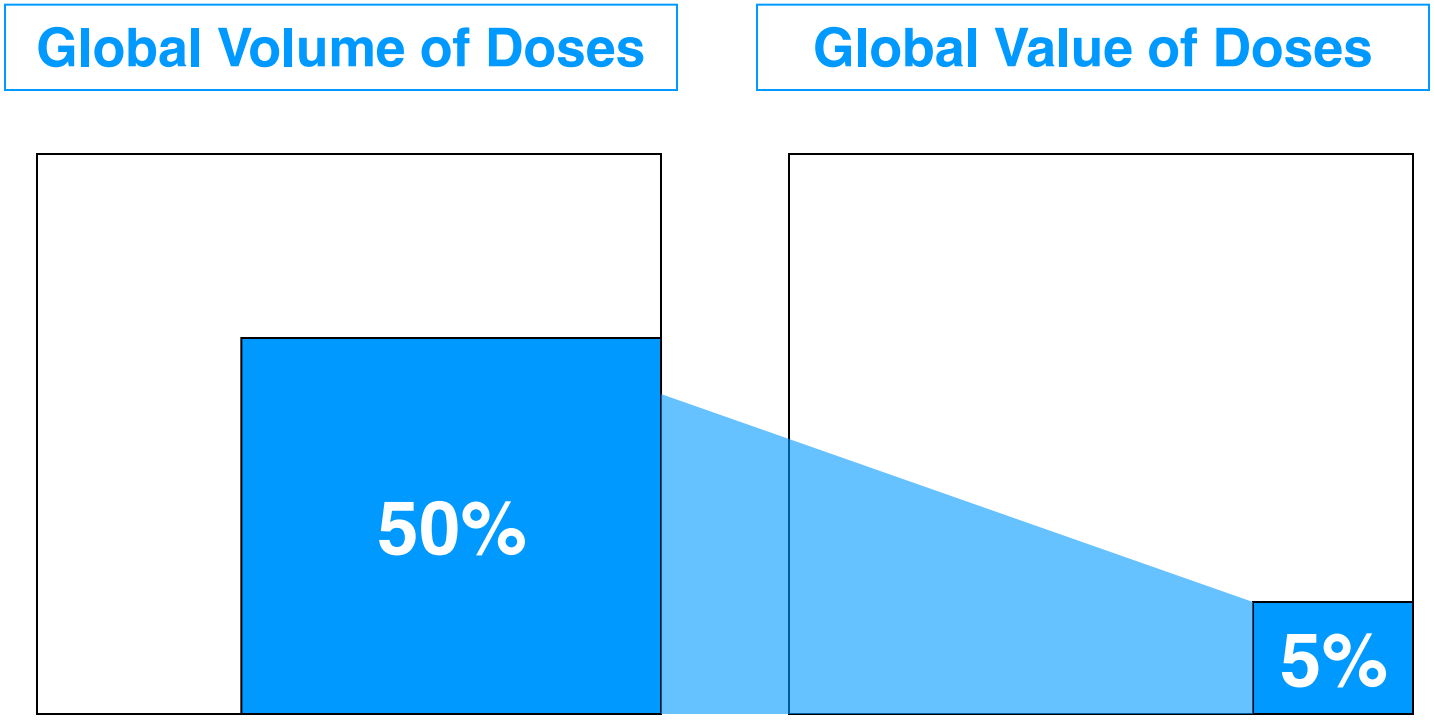


The arrows indicate the main programme drivers for the increased procurement value.

Source UNICEF Supply Division

World Health Organization

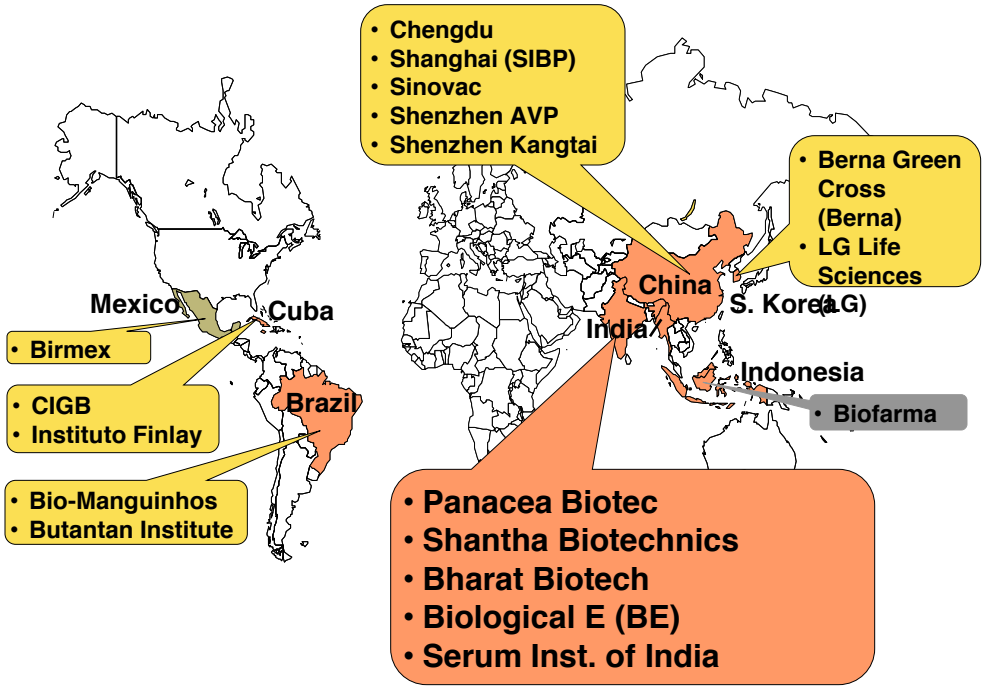
The UNICEF 2012: buying 50% of the global volume of vaccine doses, mainly EPI vaccines, but representing only 5% of total market value



Sources. UNICEF SD

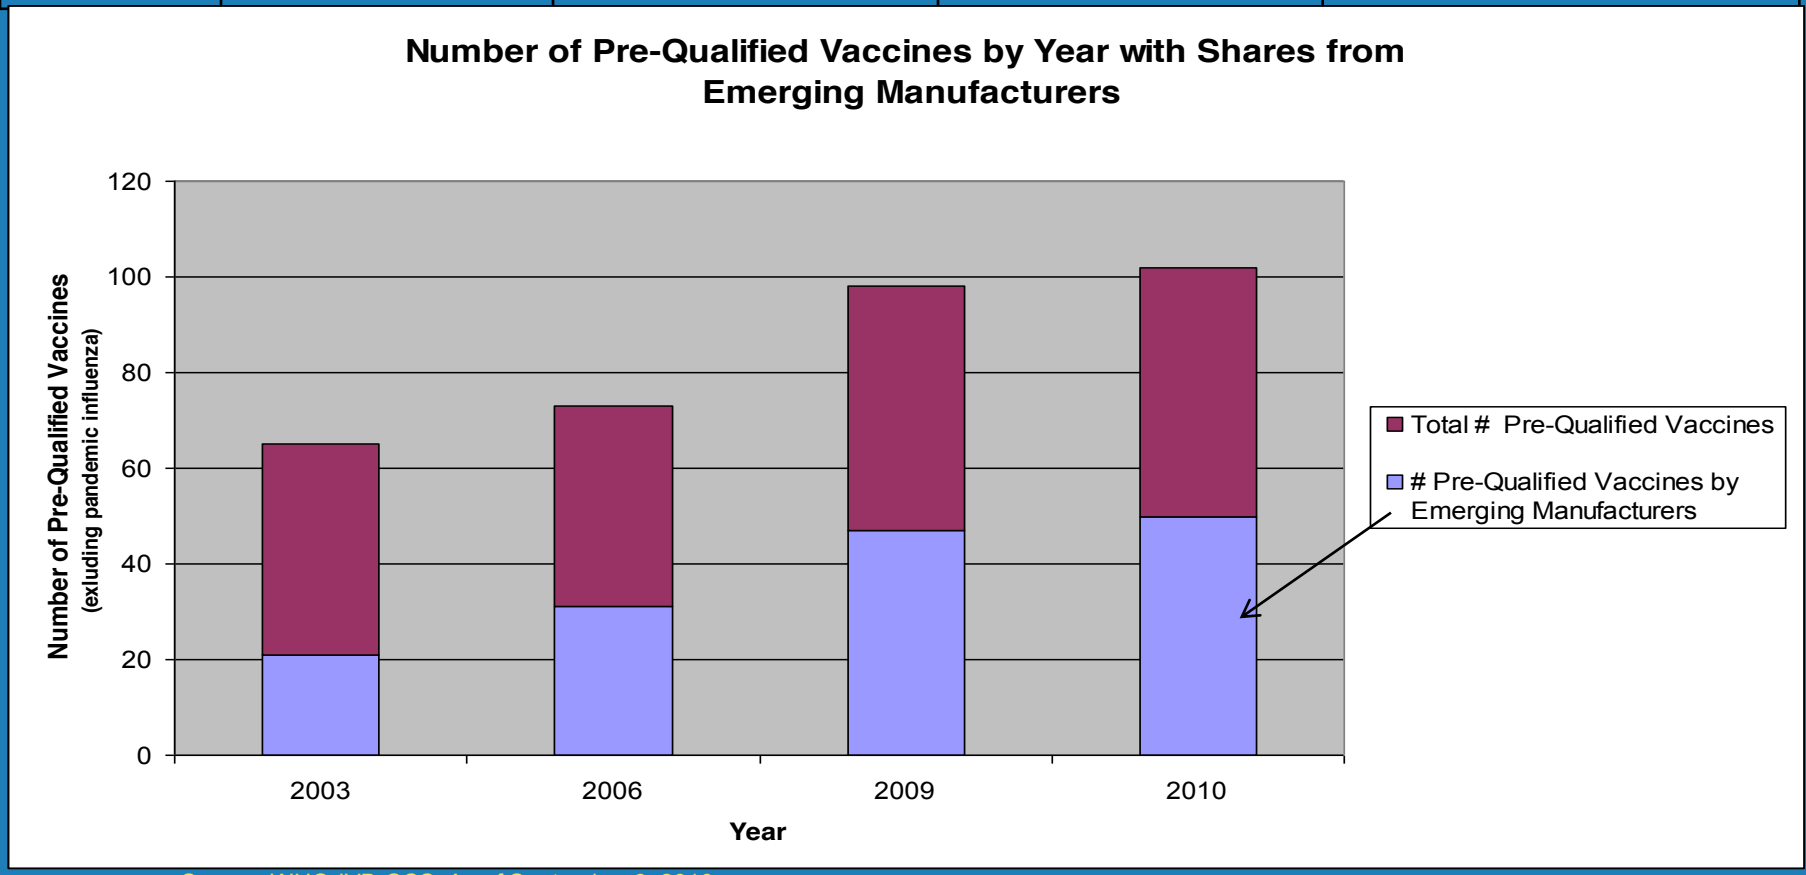
World Health Organization

EMERGING MANUFACTURERS ARE PLAYING AN ACTIVE ROLE



World Health Organization

Year	Total # Pre-Qualified Vaccines (excluding pandemic influenza)	# Pre-Qualified Vaccines by Emerging Manufacturers (excluding pandemic influenza)	% of Pre-Qualified Vaccines by Emerging Manufacturers	# Emerging Manufacturer Countries with Functional NRA's
2003	66	21	32.3%	6
2006	73	31	42.5%	6
2009	98	47	48.0%	6
2010	102	50	49.0%	7

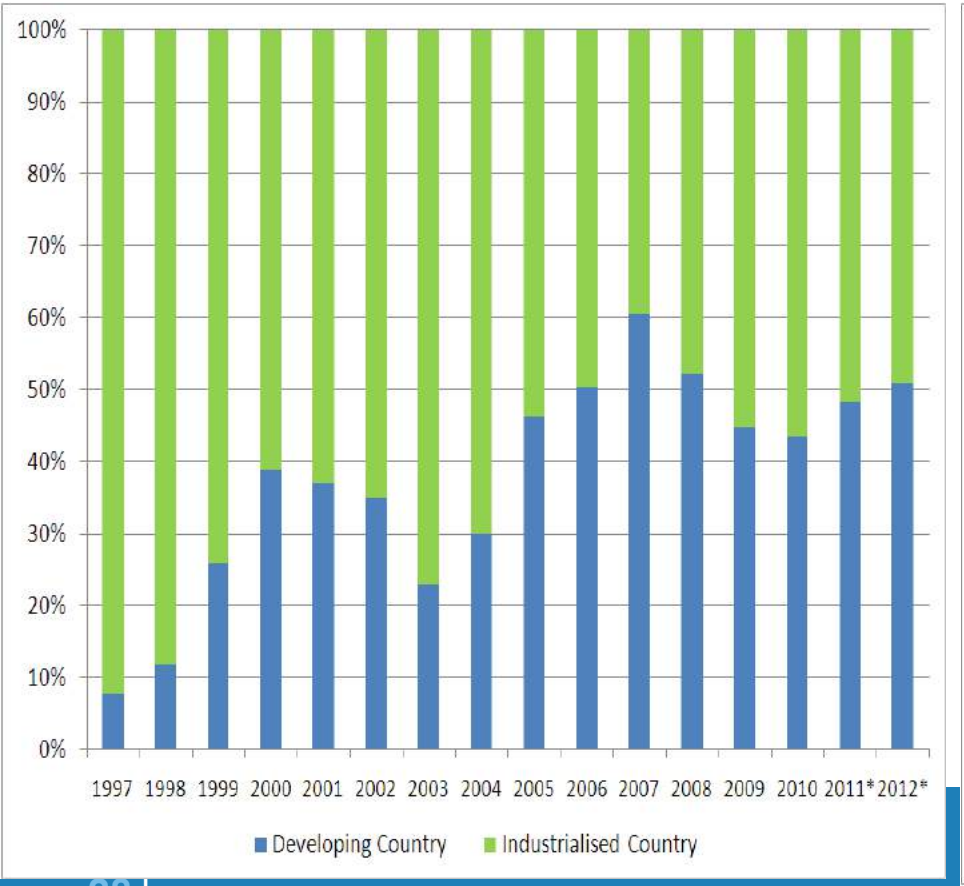


Source: WHO-IVB-QSS. As of September 6, 2010

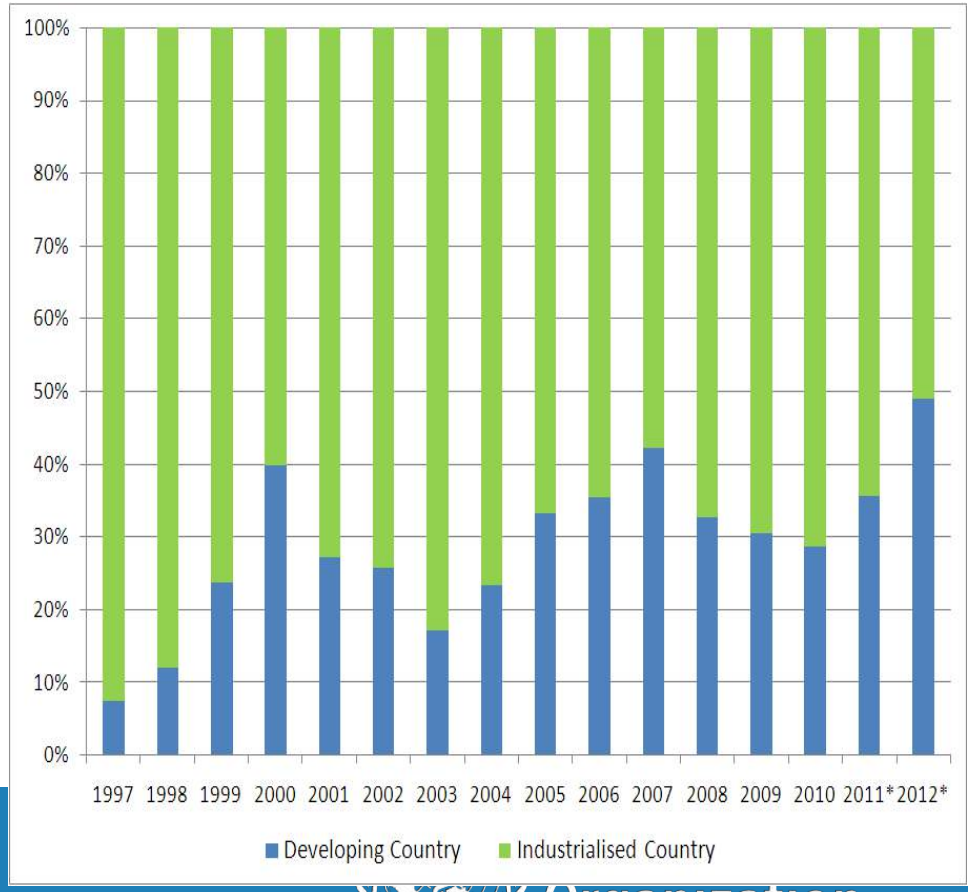
UNICEF SD
Emerging vs. Industrialized manufacturers

Emerging Market Country Manufacturers make up approximately 50% of procurement volumes in 2010 and 30% by value, predominantly due to lower but increasing participation in new vaccine markets and differing cost bases

By Volume

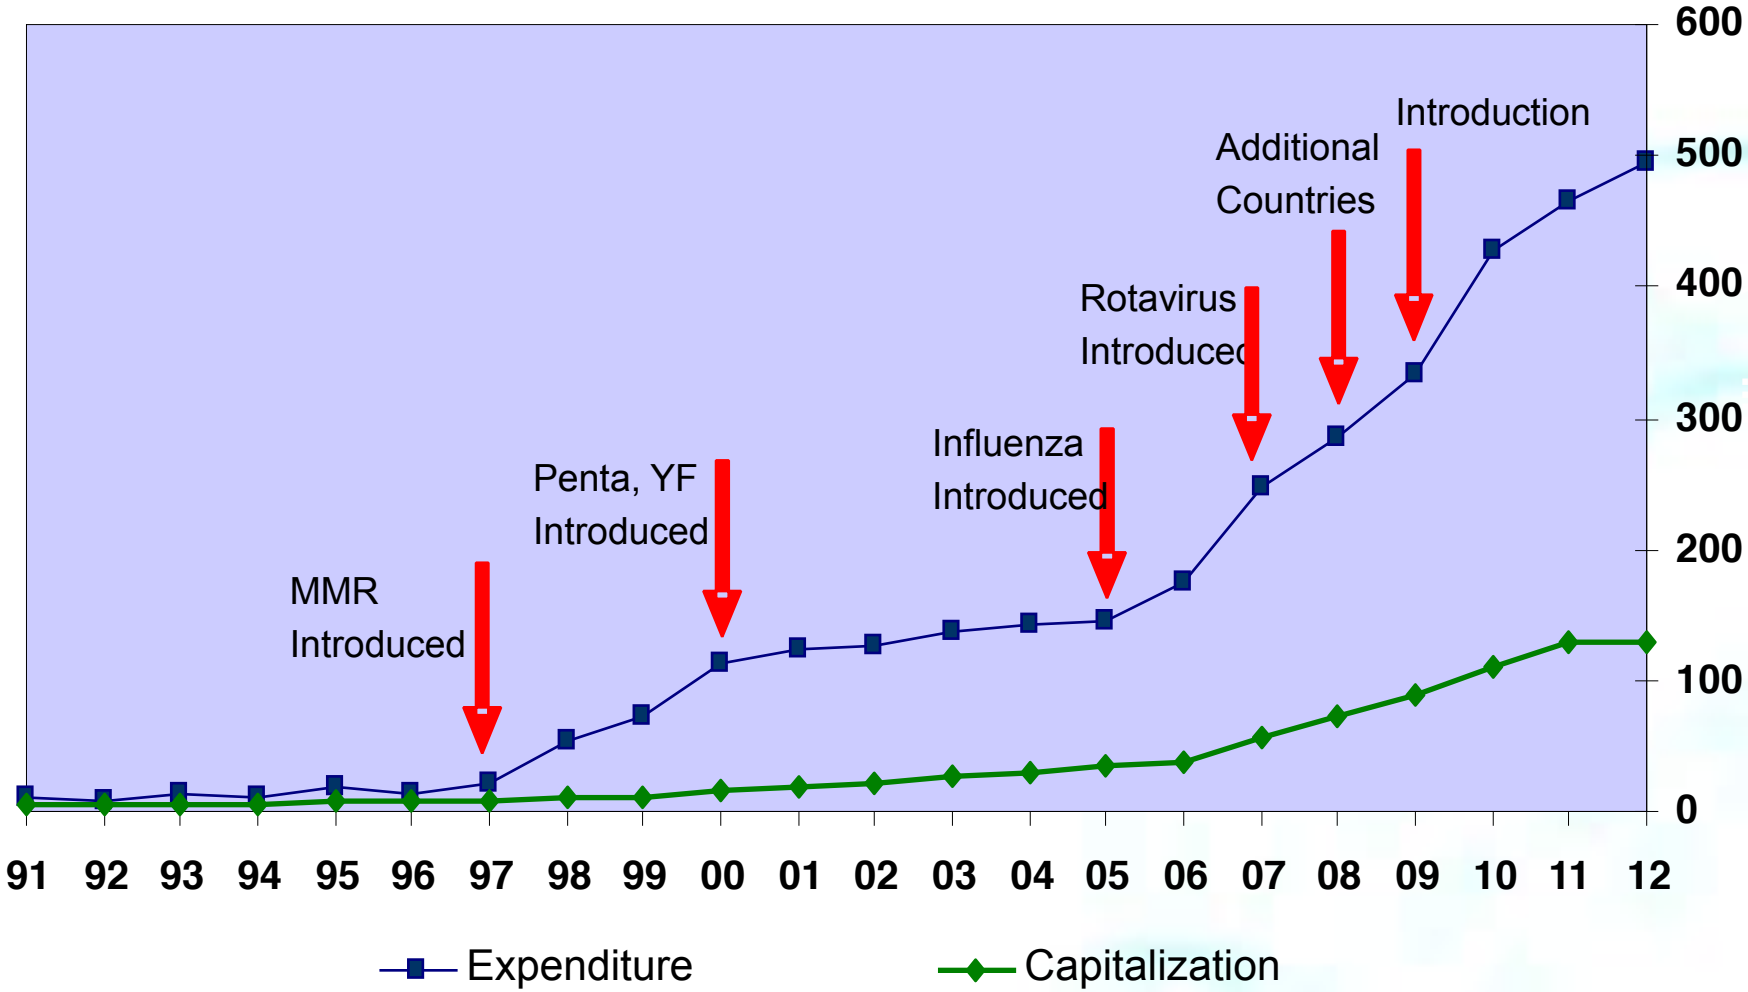


By Value



**2010 – 2012 Data based on awards already made by UNICEF*

Growth of the PAHO Revolving Fund



Source : WHO PAHO

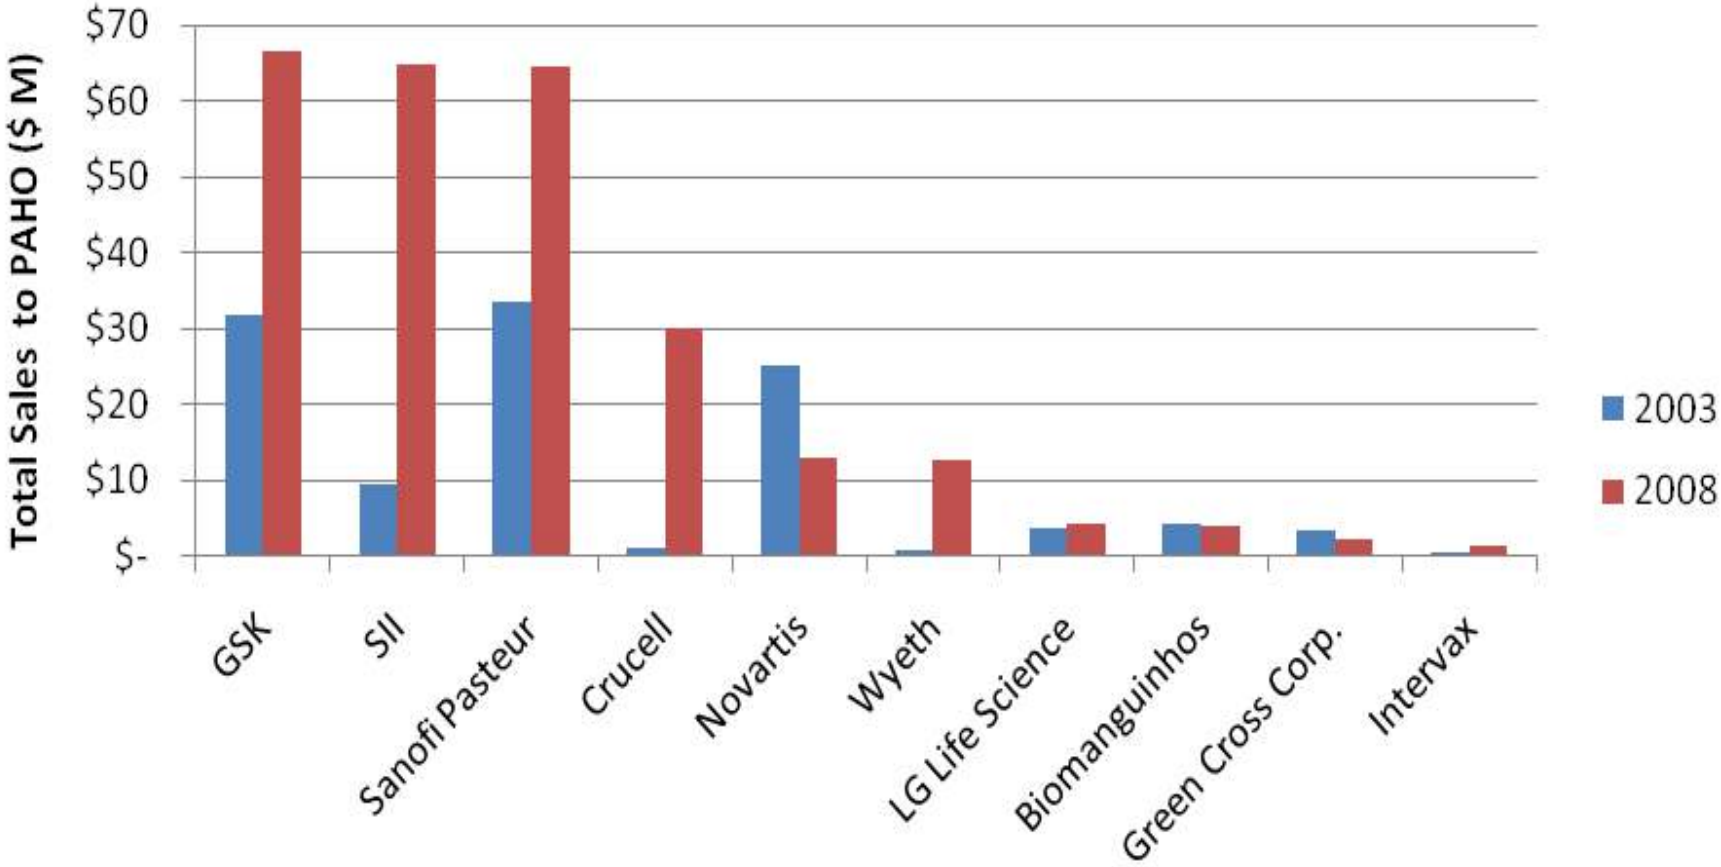
The PAHO Revolving Fund Update: 2012

60 products
28 antigens

39 countries & territories

Expected Purchases:US$ 405 million
Capital Fund: US$ 100 million

Top ten suppliers of PAHO RF 2003-2008



In 2008, no one manufacturer accounted for more than 23% of PAHO purchases

World Health Organization

NEW TRENDS ?

New trends ?

Demand side

- Vaccines and vaccinations : on the top of GoV and UN agenda, unmet needs
- Accelerate uptake and increasing demand in LIC
- Middle Income countries including emerging Countries

Supply

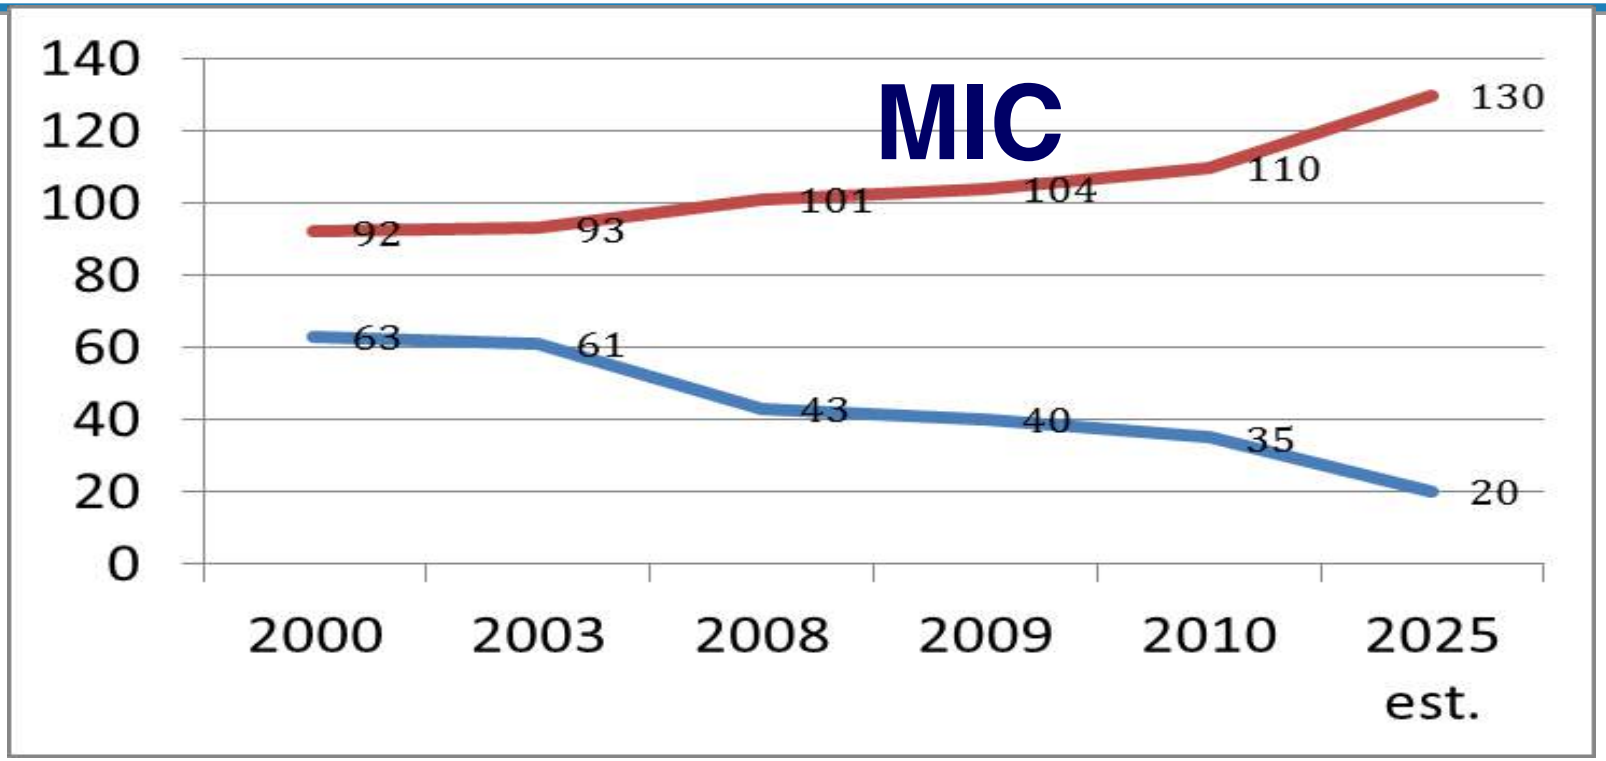
- Increasing capacity
- Remaining tensions on products
- New production and supply strategies

Funding

- GoV resources
- Donors
- Private foundations

More players on demand, supply and financing

By 2025, there will only be 20 LICs



Number of countries by income classification and year
RED = MIC;
BLUE = LIC
Source: Leo and Moss, 2011
CGD A. Glassman

Development of "MIC vaccine market products"

World Health Organization

New trends in the last 5 years and their implications

1) Supply side

- Newcomers: Pfizer, Novartis, Johnson and Johnson,..
- New contractual arrangements between MNF/EM/EE
- Outsourcing of production in developing countries
- New commercial and marketing strategies (high volume/lower price, donation, active marketing,..)
- Product/market segmentation and differential pricing
- MNC: new products and presentations with high return,
- EM: basic and underutilized products high volume/low price
- Persistent supply tensions (basic and new vaccines)

Variety of tools to accelerate new vaccine access and to manage risks

- Innovative procurement approaches as pull mechanisms (AMC)
- Push mechanisms to accelerate vaccine supply (such as Men A)
- Long term commitments may be needed to fund vaccines to stimulate capacity expansion (such as YF)

New supply and procurement strategies

- Reduce risks for both producers and purchasers
- Increase predictability and co-responsabilities

Innovative Finance Achieving Results

Tools Used	Transaction Examples	Goal
Volume Guarantee & Prepayment	Rotavirus Vaccine: • Volume guarantee provided for a portion of the quantities with some volumes paid for in advance • Contract duration of 5-years covering 132M doses • New vaccine launched and sustained at lower price • Financing provided by GAVI, with strategic and technical support from the Gates Foundation ("BMGF")	• $15 per course → €3.76 per course • >$400M in savings over 5 years • Prepayment understood to facilitate expected expansion of manufacturing capacity • Accelerated introduction of Rotavirus vaccine made possible through certainty provided by commitment in new markets
Volume Guarantee	Oral Polio Vaccine (OPV): • Firm contract signed for 2011-2012 with large bulk and fill-finish manufacturer who at the time was considering exit of market • Duration of 2-years originally covering 270M doses per year (540M doses total) • Financing provided by BMGF	• Decrease in price offered to <$0.118 per dose generated significant savings versus current WAP of >$0.13 • Delayed exit of manufacturer by >2 years • Increased visibility for manufacturer and certainty of UNICEF procurement during fragile OPV market
Volume Guarantee & Prepayment	Pentavalent Vaccine (lyophilised): • Contract signed with new entrant to Pentavalent market with volume paid for in advance • Duration for <1 year covering 10M doses • Financing provided by GAVI	• New entrant to market secured volume and able to offer extremely attractive price of $1.80 per dose, • Expanded vaccine security with expanded manufacturing capacity in a fragile market
Volume Guarantee	PCV • Volume guarantees for 20/10/5% of quantities or years 1/2/3 of 10 year contract • Financing provided by GAVI and WB	• Part of overall AMC structure to achieve tail price of max. $3.50 and sufficient production quantities to meet demand

Source: UNICEF SD, DCVMN meeting, Nov 2012

Vaccine Market: Positive trends and Main Issues

- **Positive trends**

  - Immunizations: on the top of the agenda: DOV ands GVAP
  - Promising vaccine pipeline, R&D
  - Growing support: GAVI partners + Gov funding
  - Multiple initiatives, PDPs and PPPs
  - New players on supply and funding
  - More WHO PQ vaccines leading to competition, price decrease
  - Strategic role of UNICEF SD and PAHO and increasing role of funders

- **Concerns :**

  - Oligopoly, limited supply for DC and Shortage risks
  - Upstream factors : Technology transfer and IPRs, R&D for most needed vaccines, DCVM R&D capacity , ..
  - New vaccine costs and prices
  - Financial sustainability ? Govt responsibilities role
  - Future of International initiatives
  - Future of Emerging Manufacturers
  - Impact of the financial crisis?

INSTITUTE OF MEDICINE
OF THE NATIONAL ACADEMIES

Advising the Nation. Improving Health.

THE NATIONAL ACADEMIES

Advisers to the Nation on Science, Engineering, and Medicine

The **National Academy of Sciences** is a private, nonprofit, self-perpetuating society of distinguished scholars engaged in scientific and engineering research, dedicated to the furtherance of science and technology and to their use for the general welfare. Upon the authority of the charter granted to it by the Congress in 1863, the Academy has a mandate that requires it to advise the federal government on scientific and technical matters. Dr. Ralph J. Cicerone is president of the National Academy of Sciences.

The **National Academy of Engineering** was established in 1964, under the charter of the National Academy of Sciences, as a parallel organization of outstanding engineers. It is autonomous in its administration and in the selection of its members, sharing with the National Academy of Sciences the responsibility for advising the federal government. The National Academy of Engineering also sponsors engineering programs aimed at meeting national needs, encourages education and research, and recognizes the superior achievements of engineers. Dr. Charles M. Vest is president of the National Academy of Engineering.

The **Institute of Medicine** was established in 1970 by the National Academy of Sciences to secure the services of eminent members of appropriate professions in the examination of policy matters pertaining to the health of the public. The Institute acts under the responsibility given to the National Academy of Sciences by its congressional charter to be an adviser to the federal government and, upon its own initiative, to identify issues of medical care, research, and education. Dr. Harvey V. Fineberg is president of the Institute of Medicine.

The **National Research Council** was organized by the National Academy of Sciences in 1916 to associate the broad community of science and technology with the Academy's purposes of furthering knowledge and advising the federal government. Functioning in accordance with general policies determined by the Academy, the Council has become the principal operating agency of both the National Academy of Sciences and the National Academy of Engineering in providing services to the government, the public, and the scientific and engineering communities. The Council is administered jointly by both Academies and the Institute of Medicine. Dr. Ralph J. Cicerone and Dr. Charles M. Vest are chair and vice chair, respectively, of the National Research Council.

AFRAH ALI, Senior Program Assistant (until November 2007)
ANDREW POPE, Director, Board on Health Sciences Policy

Acknowledgments

In preparing this report, the committee and project staff benefited greatly from the assistance and expertise of many individuals and groups. Important information and insights came from four public meetings that the committee organized to collect information and perspectives from a range of academic, professional, consumer, patient, and other organizations and individuals. A number of speakers at these meetings also shared their knowledge at other times during the course of the study. Appendix A includes the agendas of the public meetings and a list of organizations that submitted written statements of views.

The committee appreciates the contributions of the authors of the background papers that appear as Appendix C (Michael Davis at Illinois Institute of Technology and Josephine Johnston at the Hastings Center) and Appendix D (Jason Dana at University of Pennsylvania). Our project officer at the National Institutes of Health, Walter Schaffer, was always helpful in getting our questions answered. We also called on Daniel Wolfson at the American Board of Internal Medicine Foundation for information. In addition, Ariel Winter of the Medicare Payment Advisory Commission helped by answering questions about the commission's work. Mary Nix at the Agency for Healthcare Research and Quality provided data from the National Guidelines Clearinghouse that we could not obtain online. An undoubtedly incomplete list of others who assisted the committee's work includes David Atkins, James Bernat, Carol Blum, David Blumenthal, Deborah Briggs, Laura Brockway-Lunardi, Robert Campbell, Roger Chou, Vivian Coates, Allan Coukel, Bette Crigger, Susan Ehringhaus, Brian Eigel,

Susan Gilbert, Marianne Hockema, Cato Laurencin, Jeffrey Leiden, Martha Liggett, Kathleen Lohr, Peter Lurie, Charlene May, Jennifer Padberg, James Severson, Mark Sommerfeld, Gabriel Sullivan, and Myrl Weinberg.

The committee and project staff also appreciate the work of copy editor Michael Hayes. Within the National Academies, we particularly acknowledge the assistance of Clyde Behney, Judy Estep, Robert Giffin, Janice Mehler, Abbey Meltzer, Amy Packman, Donna Randall, Bronwyn Schrecker, and Jackie Turner.

Reviewers

This report has been reviewed in draft form by individuals chosen for their diverse perspectives and technical expertise, in accordance with procedures approved by the National Research Council's Report Review Committee. The purpose of this independent review is to provide candid and critical comments that will assist the institution in making its published reports as sound as possible and to ensure that the report meets institutional standards for objectivity, evidence, and responsiveness to the study charge. The review comments and draft manuscript remain confidential to protect the integrity of the deliberative process. We wish to thank the following individuals for their review of this report:

Claudia R. Adkison, Emory University School of Medicine
Robert Baron, University of California, San Francisco School of Medicine
Paul Citron, Medtronic, Inc. (Retired)
F. Sessions Cole, Washington University School of Medicine
Peter Densen, University of Iowa Carver College of Medicine
Thomas J. Fogarty, Fogarty Engineering
Leo T. Furcht, University of Minnesota
Linda Golodner, National Consumers League
Henry T. Greely, Stanford University Law School
Allen S. Lichter, American Society of Clinical Oncology
Joseph Loscalzo, Brigham and Women's Hospital
Alan Nelson, American College of Physicians Foundation

Philip A. Pizzo, Stanford University School of Medicine
Richard Schilsky, University of Chicago Medical Center
Larry J. Shapiro, Washington University in St. Louis School of Medicine
Harold Sox, Annals of Internal Medicine and American College of Physicians
Jeremy Sugarman, Johns Hopkins Medical Institutions
P. Roy Vagelos, Merck & Co., Inc. (Retired)

Although the reviewers listed above have provided many constructive comments and suggestions, they were not asked to endorse the conclusions or recommendations, nor did they see the final draft of the report before its release. The review of this report was overseen by **David Challoner,** University of Florida, and **Judith L. Swain,** National University of Singapore and University of California, San Diego. Appointed by the National Research Council and the Institute of Medicine, these individuals were responsible for making certain that an independent examination of this report was carried out in accordance with the institutional procedures and that all review comments were carefully considered. Responsibility for the final content of this report rests entirely with the authoring committee and the institution.

Preface

Hardly a week goes by without a news story about conflicts of interest in medicine. While this committee met, colleagues and friends sent me many news reports and journal articles on the topic. These reports—even if one expects that initial news reports may not always have the stories quite straight—served as continual reminders that conflicts of interest create deep concerns about the integrity of medicine and medical research and raise questions about the trustworthiness of physicians, researchers, and medical institutions.

As I look back over our deliberations, several themes stand out. First, as with all Institute of Medicine (IOM) reports, the committee was charged with making recommendations that were based on evidence and convincing reasons. Although the committee members were aware of powerful anecdotes and had personal beliefs about the issues, we repeatedly asked whether the evidence supported our conclusions and recommendations. If it did not, we developed a reasoned case on the basis of the committee's experience and the judgment of the committee members about the arguments for the use of different approaches presented in the literature or in statements submitted to the committee. Second, it is a challenge to craft policy recommendations that strike the right balance between addressing egregious cases and creating burdens that stifle relationships that advance the goals of professionalism and generate knowledge to benefit society. The committee tried to consider the possibility that well-intentioned policies may have unintended adverse consequences. Third, regulation alone may have limited effectiveness in the absence of a culture of professionalism

and other incentives that are aligned to promote professional behavior. The committee considered how a variety of organizations—including those that accredit health care institutions and license health care professionals, publish the findings of medical research, use practice guidelines, and pay for medical care—can buttress the conflict of interest policies implemented by institutions that carry out medical research, provide education and patient care, and develop practice guidelines.

This report cannot and did not attempt to resolve all issues related to conflicts of interest in medicine. In view of our expansive charge, we tried to address central questions rather than the many details of this complex topic. For example, we focus on conflicts that involve financial interests because they are at the heart of concerns and debates about conflicts of interest. Furthermore, because relationships with pharmaceutical, medical device, and biotechnology companies have created the greatest concern and were central in the discussions that led the IOM to pursue this study, we focused on those relationships. The committee expects that many of the recommendations and analyses in our report will also apply more generally to professional and institutional relationships with other commercial entities, such as insurers and vendors of nonmedical products.

The committee could not resolve some important issues like harmonizing the different requirements for the disclosure of financial relationships because they would require much more time and additional expertise. Instead, to standardize aspects of disclosure policies and procedures, the committee recommended a focused consensus development process that would involve multiple stakeholders on the issue.

Our committee was diverse, involving members with different professional backgrounds and areas of expertise. These different perspectives led to spirited discussions and debates. Each of us listened to points of view and information that we had not previously considered. We tried to listen to and understand other viewpoints and be open to new perspectives, even if in the end we did not agree on all issues. Appendix F describes the different views on one issue, a proposal by some committee members for broader requirements for public disclosure. In general, the committee hoped that by explaining our reasoning on difficult issues our audiences would better appreciate the multiple considerations that a sound conflict of interest policy should address.

As chair, I want to personally thank the committee members for their hard work and their willingness to engage on difficult topics. I am deeply grateful to them for the time and effort that they took from their busy schedules to devote to this project. This report is truly a collaborative effort and is much the better, I think, for the back-and-forth discussions. I also want to personally thank our IOM staff for their tremendous efforts in making this report possible. Robin Parsell skillfully handled meeting

and other logistics, and Franklin Branch provided research assistance in many areas. Marilyn Field was unstinting in her background research, drafting and revising of the manuscript, and high standards for our work. And I want to thank Lindsay Parham, my research assistant at the University of California at San Francisco, for her expert help with background research.

Summary

ABSTRACT

Patients and the public benefit when physicians and researchers collaborate with pharmaceutical, medical device, and biotechnology companies to develop products that benefit individual and public health. At the same time, concerns are growing that wide-ranging financial ties to industry may unduly influence professional judgments involving the primary interests and goals of medicine. Such conflicts of interest threaten the integrity of scientific investigations, the objectivity of professional education, the quality of patient care, and the public's trust in medicine.

This Institute of Medicine report examines conflicts of interest in medical research, education, and practice and in the development of clinical practice guidelines. It reviews the available evidence on the extent of industry relationships with physicians and researchers and their consequences, and it describes current policies intended to identify, limit, or manage conflicts of interest. Although this report builds on the analyses and recommendations of other groups, it differs from other reports in its focus on conflicts of interest across the spectrum of medicine and its identification of overarching principles for assessing both conflicts of interest and conflict of interest policies. The report, which offers 16 specific recommendations, has several broad messages.

- *The central goal of conflict of interest policies in medicine is to protect the integrity of professional judgment and to preserve public trust rather than to try to remediate bias or mistrust after it occurs.*
- *The disclosure of individual and institutional financial relationships*

is a critical but limited first step in the process of identifying and responding to conflicts of interest.

- *Conflict of interest policies and procedures can be strengthened by engaging physicians, researchers, and medical institutions in developing policies and consensus standards.*
- *A range of supporting organizations—including accrediting groups and public and private health insurers—can promote the adoption and implementation of conflict of interest policies and promote a culture of accountability that sustains professional norms and public confidence in medicine.*
- *Research on conflicts of interest and conflict of interest policies can provide a stronger evidence base for policy design and implementation.*
- *If medical institutions do not act voluntarily to strengthen their conflict of interest policies and procedures, the pressure for external regulation is likely to increase.*

Physicians and researchers must exercise judgment in complex situations that are fraught with uncertainty. Colleagues, patients, students, and the public need to trust that these judgments are not compromised by physicians' or researchers' financial ties to pharmaceutical, medical device, and biotechnology companies. Ties with industry are common in medicine. Some have produced important benefits, particularly through research collaborations that improve individual and public health. At the same time, widespread relationships with industry have created significant risks that individual and institutional financial interests may unduly influence professionals' judgments about the primary interests or goals of medicine. Such conflicts of interest threaten the integrity of scientific investigations, the objectivity of medical education, and the quality of patient care. They may also jeopardize public trust in medicine.

Surveys show the breadth and diversity of relationships between industry and physicians, researchers, and educators in academic and community settings. For example,

- gifts from drug companies to physicians are ubiquitous;
- visits to physicians' offices by drug and medical device company representatives and the provision of drug samples are widespread;
- many faculty members receive research support from industry, and industry funds the majority of biomedical research in the United States;
- many faculty members and community physicians provide scientific, marketing, and other consulting services to companies; and some serve on company boards of directors or on industry speakers bureaus; and
- commercial sources provide about half of the total funding for accredited continuing medical education programs.

Although certain of these financial relationships may be constructive, recent news reports, legal settlements, research studies, and institutional announcements have documented a variety of disturbing situations that could undermine public confidence in medicine. These situations include

- physicians and researchers failing to disclose substantial payments from drug companies, as required by universities, government agencies, or medical journals;
- settlements with the U.S. Department of Justice by medical device and pharmaceutical companies to avoid prosecution for alleged illegal payments or gifts to physicians;
- companies and academic investigators not publishing negative results from industry-sponsored clinical trials or delaying publication for over a year after the completion of a trial;
- academic researchers putting their names on manuscripts, even though they first became involved after the data were collected and analyzed and after the first drafts were written by individuals paid by industry; and
- professional societies and other groups that develop clinical practice guidelines choosing not to disclose their industry funding and not to reveal the conflicts of interest of the experts who draft the guidelines.

Although the causes of these situations are various and their extent is unclear, they highlight the tension that may exist between financial relationships with industry and the primary missions of medical research, education, and practice. In addition to these examples, research on industry gifts and other financial relationships has generated troublesome findings. For example, systematic reviews of the evidence sponsored by a pharmaceutical company are more likely than other reviews to present conclusions favorable to the company, even when the actual findings of the analysis are not favorable. In addition, articles based on company-sponsored clinical trials are more likely to draw conclusions favorable to the company's product than articles trials not sponsored by industry. Although these findings do not necessarily show that the research is biased and other explanations can be offered (e.g., companies do not fund trials unless they see a reasonable likelihood of success), they do raise legitimate questions about possible undue influence.

To cite another example, the availability of drug samples may be associated with the prescription of new brand name drugs when they are not recommended by evidence-based practice guidelines or when appropriate but less expensive drugs or generic equivalents are available for the same indication. Although one argument for the use of drug samples is that they help low-income patients, research suggests that these individuals are not the

primary recipients of such samples. Also, although small gifts to physicians may seem to be inconsequential, some research suggests that small gifts can contribute to unconscious bias in decision making and advice giving. It also seems unlikely that companies would give such gifts to physicians if they did not believe that they would benefit the company in some way.

In addition to information that raises concern about the scope and consequences of industry financial ties in medicine, surveys and other studies have reported inconsistencies in the adoption and implementation of conflict of interest policies by medical institutions. Relationships and practices that are forbidden by one institution may be allowed and even encouraged by others. Reports also have described shortcomings in the oversight of conflicts of interest in research by federal agencies and medical institutions.

Unfortunately, the empirical evidence relevant to financial relationships and conflicts of interest is limited. On many topics related to conflicts of interest, no systematic studies are available. For other topics, data are suggestive rather than definitive. The studies that have been conducted have primarily been observational rather than interventional, in large part because the issues cannot be investigated using randomized controlled trials of the effects of different kinds of relationships or different approaches to identifying and managing conflicts of interest. A number of academic medical centers, professional associations, and other institutions have taken steps to strengthen their conflict of interest policies, but few data that can be used to assess the consequences—positive or negative—of these changes are available. Some prominent physicians and researchers have argued that concerns about conflicts of interest are far out of proportion to the evidence that they exist or are harmful, and some contend that measures designed to address conflicts of interest have interfered with beneficial collaborations with industry. Critics of conflict of interest policies have also charged that the great majority of individuals who have not acted in an unethical manner may be subjected to onerous regulations and tacit conclusions that they are culpable of misconduct until proven otherwise.

Responding to the situations and concerns outlined above, the Institute of Medicine appointed a committee to investigate and develop a consensus report on conflicts of interest in medical research, education, and practice and in the development of clinical practice guidelines. Consistent with its charge, the committee

- examined conflicts of interest in medical research, education, and practice and in the development of clinical practice guidelines and
- developed analyses and recommendations to inform the design and implementation of policies that identify and manage conflicts of interest in these contexts without damaging constructive collaborations with industry.

Because the evidence on many issues is limited, the committee had to rely on its experience and judgment in evaluating the analyses and arguments presented in the literature and in statements submitted to the committee. During its work, the committee kept in mind the core goals of medical research, education, and practice and practice guideline development, which include serving the best interests of patients and society through the generation of valid scientific knowledge, the independent evaluation of evidence and the application of critical thinking, and the creation and use of evidence-based recommendations for patient care.

Reflecting concerns that were raised during the planning of the project and the central issues in debates and policies on conflicts of interest in medicine, the committee focused on financial relationships involving pharmaceutical, medical device, and biotechnology companies. Although it did not investigate in depth the conflicts of interest associated with different physician payment arrangements or with physician referral of patients to facilities in which they have an ownership interest, the committee recognized the seriousness of those types of conflicts and the difficulties that policy makers have encountered in trying to eliminate or manage them. It also recognized other sources of conflicts of interest, for example, desires for professional advancement and recognition.

After examining a wide array of evidence, analyses, and perspectives on conflicts of interest, the committee reached several overarching conclusions. They are as follows:

- The goals of conflict of interest policies in medicine are primarily to protect the integrity of professional judgment and to preserve public trust rather than to try to remediate bias or mistrust after they occur.
- The disclosure of individual and institutional financial relationships is a critical but limited first step in the process of identifying and responding to conflicts of interest.
- Conflict of interest policies and procedures can be strengthened by engaging physicians, researchers, and medical institutions in developing conflict of interest policies and consensus standards.
- A range of supporting organizations—public and private—can promote the adoption and implementation of conflict of interest policies and help create a culture of accountability that sustains professional norms and public confidence in professional judgments.
- Research on conflicts of interest and conflict of interest policies can provide a stronger evidence base for policy design and implementation.
- If medical institutions do not act voluntarily to strengthen their conflict of interest policies and procedures, the pressure for external regulation is likely to increase.

PRINCIPLES FOR IDENTIFYING AND ASSESSING CONFLICTS OF INTERESTS

Chapter 2 presents the principles and conceptual framework for identifying and assessing conflicts of interest. Conflicts of interest are defined as *circumstances that create a risk that professional judgments or actions regarding a primary interest will be unduly influenced by a secondary interest*. Primary interests include promoting and protecting the integrity of research, the quality of medical education, and the welfare of patients. Secondary interests include not only financial interests—the focus of this report—but also other interests, such as the pursuit of professional advancement and recognition and the desire to do favors for friends, family, students, or colleagues. Conflict of interest policies typically focus on financial gain because it is relatively more objective, fungible, and quantifiable. Financial gain can therefore be more effectively and fairly regulated than other secondary interests.

The severity of a conflict of interest depends on (1) the likelihood that professional decisions made under the relevant circumstances would be unduly influenced by a secondary interest and (2) the seriousness of the harm or wrong that could result from such an influence. The likelihood of undue influence is affected by the value of the secondary interest, its duration and depth, and the extent of discretion that the individual has in making important decisions.

Conflict of interest policies generally emphasize prevention and management rather than punishment. They do not assume that any particular professional will necessarily let financial gain influence his or her judgment. Likewise, a judgment that someone has a conflict of interest does not imply that the person is unethical. Such judgments assume only that some situations are generally recognized to pose an unacceptable risk that decisions may be unduly influenced by considerations that should be irrelevant. Chapter 2 presents criteria, described in the list that follows, that can be used to evaluate conflict of interest policies.

- Proportionality. Is the policy effective, efficient, and directed at the most important and most common conflicts? Conflict of interest policies and procedures may create harms or burdens as well as benefits. Do the policies and their implementation unnecessarily interfere with the conduct of legitimate research, teaching, and clinical practice?
- Transparency. Is the policy comprehensible and accessible to the individuals and institutions that it may affect? Such transparency is essential to determine if conflict of interest policies are reasonable and are being implemented fairly. Transparency can also help institutions learn

from each other about more and less successful ways of handling particular situations.

- Accountability. Does the conflict of interest policy indicate who is responsible for monitoring, enforcing, and revising it? Leaders of accountable institutions explain institutional policies and monitor and accept responsibility for the consequences, both beneficial and harmful.
- Fairness. Does the policy apply equally to all relevant groups within an institution and in different institutions? In an academic medical center, the relevant groups would include faculty, medical staff, students, residents, fellows, members of institutional committees (e.g., institutional review boards, formulary committees, panels developing practice guidelines, and device purchasing committees), and senior institutional officials.

POLICIES ON CONFLICTS OF INTEREST: OVERVIEW AND EVIDENCE

Concerns about conflicts of interest in medicine have a long history, and responses to these conflicts have evolved as relationships with industry have grown more frequent and more complex and as different responses to such relationships have been tried and found in need of modification. Government regulations and voluntary codes of conduct often follow the discovery of instances of questionable or inappropriate relationships and conduct. Government scrutiny of financial relationships and conflicts of interest may also stimulate private, voluntary efforts by academic and other institutions to deal with problems and avoid regulation.

The conflict of interest policies of academic medical centers, professional societies, medical journals, and other institutions vary on many dimensions. It is not clear that all medical institutions have conflict of interest policies. Those that do have such policies vary in what they ask physicians and researchers to disclose about their financial relationships with industry. Such variations may create additional administrative burdens for physicians and researchers who act in multiple roles and make multiple disclosures of their financial relationships with industry to different institutions for various purposes related to medical research, education, and clinical care and clinical practice guideline development.

Institutions also vary in what relationships they prohibit because they view them as creating unacceptable risks of undue influence on primary interests, and they also differ in how they manage conflicts of interest that are not prohibited. The National Institutes of Health (NIH) has identified variations and deficiencies in how research institutions implement the 1995 U.S. Public Health Service (PHS) regulations on conflict of interest, and it has advised institutions on steps that they can take to strengthen their poli-

cies. Similarly, the Association of American Medical Colleges (AAMC) and the Association of American Universities (AAU) have developed recommendations and guidance on conflict of interest policies governing research with human participants, but surveys indicate that research institutions have not fully implemented these recommendations.

Although the disclosure of financial interests or conflicts of interest is a necessary part of conflict of interest policies, it is not sufficient in itself to safeguard the integrity of professional judgment or to maintain public trust. For example, when a relationship or conflict of interest is disclosed to individual patients, students, or research participants, they often lack the knowledge and perspective to assess the relationship and may have no satisfactory options if they have concerns about it. Conflicts that are disclosed but not eliminated or managed can continue to pose risks to judgment and undermine public trust.

The recommendations in Chapter 3 establish the fundamental elements of an effective policy response to conflicts of interest in medical research, education, and practice. Recommendation 3.1 calls on all institutions engaged in these activities to establish conflict of interest policies and create conflict of interest committees to evaluate and manage conflicts. Recommendation 3.2 focuses on the essential policy step of requiring physicians, researchers, and senior officials to disclose to their institutions their financial relationships with industry. Unless institutions are informed of these relationships, they cannot identify conflicts of interest or determine whether additional steps—such as the elimination or management of the conflict—are needed to reduce the risk of bias or a loss of public trust. Recommendations 3.1 and 3.2 are similar to the recommendations made in other reports on conflict of interest; but they extend to all institutions that carry out medical research, medical education, clinical care, and practice guideline development.

The disclosure of financial relationships can be effective only if it provides sufficient information for others to use in assessing a relationship and judging the severity of a conflict. At the same time, disclosure can be burdensome, particularly for physicians who must make multiple disclosures for different activities. Recommendation 3.3 calls for the standardization of disclosures with the goals of providing institutions with the specific information that they need to assess relationships while reducing the reporting burdens on physicians and researchers. Such standardization is best pursued through a consensus development process that involves a broad array of concerned parties (e.g., academic medical centers, professional societies, public interest groups, and NIH and other public agencies). On the basis of the agreements resulting from this process, the next step would be for software developers to produce computer programs that allow an individual to fill out a standard questionnaire and then format the information for differ-

ent institutions and purposes. This should reduce the burden on individuals and increase the consistency of the information disclosed.

Even with further policy development and standardization, institutions will still face questions about the completeness and accuracy of the information disclosed to them. Recommendation 3.4 calls for the U.S. Congress to create a national program that requires pharmaceutical, medical device, and biotechnology companies and their foundations to publicly report payments to physicians, researchers, health care institutions, professional societies, patient advocacy and disease-specific groups, providers of continuing medical education, and foundations created by any of these entities. Although many details will need to be worked out, the information should be readily available on a secure, searchable public website that allows the identification and aggregation of all payments that an individual or institution receives from all companies. Such a program of company reporting will enhance accountability by allowing universities, journals, and others to verify the disclosures that have been made to them. It may also discourage the formation of questionable relationships that individuals or companies would prefer not be widely known.

CONFLICTS OF INTEREST IN BIOMEDICAL RESEARCH

Research partnerships among industry, academia, and government are essential to the discovery and development of new medications and medical devices that improve the prevention, diagnosis, and treatment of health problems. Chapter 4 reports on evidence that relationships between academic researchers and industry are widespread and are associated with benefits, for example, greater research productivity. At the same time, evidence suggests that these relationships have risks, including decreased openness in the sharing of data and findings and the withholding of negative results. These kinds of risks justify additional requirements and incentives, as recommended in this report, for institutions to adopt and implement policies to identify and eliminate or manage conflicts of interest.

Consistent with the recommendations of AAMC and AAU, Recommendation 4.1 calls for a general rule that researchers may not conduct research involving human participants if they have a financial interest in the outcome of the research, for example, if they hold a patent on an intervention being tested in a clinical trial. Exceptions should be allowed only if an individual's participation is judged to be essential for the safe and appropriate conduct of the research. An example might be the inventor of a complex new implanted medical device who has unique expertise and technical skills that are essential for the safe implantation of the device during pilot or early-phase studies. If a conflict of interest committee approves the involvement of such a researcher, it should take advantage of the full range of options

for managing the conflict, including placing restrictions on the researcher's role in the study.

Although Recommendation 4.1 does not cover nonclinical research, financial relationships in this arena may also create risks of undue influence that institutions should assess and manage as appropriate to protect the integrity of the science. Additional studies on financial relationships in nonclinical research, their risks and consequences, and the ways in which institutions identify and respond to these relationships would help establish an evidence base that could be used to guide judgments about policies in this area.

CONFLICTS OF INTEREST IN UNDERGRADUATE, GRADUATE, AND CONTINUING MEDICAL EDUCATION

Chapter 5 presents strong evidence that relationships with industry are pervasive in undergraduate, graduate, and continuing medical education. Most medical students and residents are exposed to lunches, gifts, and other interactions with pharmaceutical company representatives on a frequent basis. Faculty members have extensive relationships with these individuals as well.

In analyzing relationships with industry in the context of medical education, the focus should be on the learning environment, the development of core competencies, and consistency between the formal curriculum and the informal or hidden curriculum. The key goals of medical education include helping learners at all levels develop the ability to think critically and appraise the evidence for clinical decision making. In controlled situations, some interactions with representatives of medical device companies may foster the goals of appropriate training, patient safety, and device evaluation. Otherwise, the committee found no bases for concluding that educational goals are promoted by other relationships involving gifts, most visits by pharmaceutical company representatives, service as a marketing consultant, participation in an industry speakers bureau, or acceptance of credit for a ghostwritten article. Indeed, the evidence suggests that some of these relationships are associated with undue influence and thus undermine the goals of medical education. Overall, the risks of these relationships outweigh any possible benefits.

Recommendation 5.1 therefore calls on academic medical centers to prohibit faculty, students, residents, and fellows from accepting gifts (including meals), making presentations that are controlled by industry, and claiming authorship for ghostwritten publications. This restriction is not intended to exclude the acceptance of scientific materials from industry scientists under appropriate material transfer agreements or the payment of reasonable honoraria to speakers who present their own material. Recom-

mendation 5.1 also calls for restrictions on the acceptance of drug samples and visits by drug and medical device sales representatives.

For academic medical centers and community physicians, drug samples present difficult issues. Caring for indigent patients who cannot afford needed drugs is frustrating for physicians who are trying to act in their patients' best interests. Many physicians believe that drug samples allow some patients access to drugs that they could otherwise not obtain. Nonetheless, research suggests that most samples are not in fact given to patients who lack financial access to needed medications and that physicians who have access to samples may change their prescribing habits, for example, by not prescribing the drugs that they would prefer their patients to use or by prescribing drugs in ways that are not consistent with evidence-based recommendations. The committee concluded that the lack of access to affordable medications is serious and disturbing but that drug samples are not a satisfactory answer to this societal problem. Academic medical centers should, at a minimum, oversee and restrict their use.

Because faculty, students, residents, and fellows may not understand the risks posed by conflicts of interest and the rationale for conflict of interest policies, Recommendation 5.2 calls on academic medical centers and teaching hospitals, as part of their educational mission, to provide education on the avoidance of conflicts of interest and the management of relationships with pharmaceutical and medical device industry representatives. Organizations that accredit medical schools and residency programs should develop standards to reinforce this recommendation.

Questions about conflicts of interest have been particularly visible in continuing medical education. Most physicians are required to participate in accredited continuing medical education as a condition for relicensure, specialty certification, or granting of hospital medical staff privileges. Many commercial and academic providers of accredited continuing medical education receive half or more of their funding from industry, which raises concerns about industry influence over the selection of educational topics, the content of presentations, and the overall scope of educational offerings (e.g., whether they provide sufficient coverage of such issues as prevention and physician-patient communication).

Although individual continuing medical education providers and the accrediting organization for continuing medical education have taken steps to limit industry influence, the dependence of many programs on industry funding raises doubts about how successful these steps can be. Recommendation 5.3 calls for a broad-based consensus development process to propose a new system of funding accredited continuing medical education that is free of industry influence, enhances public trust in the integrity of the system, and provides high-quality education. Some members of the committee supported a total end to industry funding, but others were concerned

about the potential for unintended harm from such a ban. The committee recognized that changes in the current system likely would substantially reduce industry funding for accredited continuing medical education. Even if education providers trim their expenses, the costs of accredited continuing medical education would likely increase for many physicians, which could be an economic burden for some physicians, for example, those in rural areas.

CONFLICTS OF INTEREST AND MEDICAL PRACTICE

As is the case in medical research and education, evidence shows that relationships with industry are widespread among physicians in practice. Physician acceptance of gifts and meals from industry representatives is commonplace, as are visits with company sales representatives. Company marketing strategies are sophisticated. As part of these strategies, physicians may be used as marketing agents, physicians' prescribing habits may be tracked through commercial databases, and companies may sponsor so-called seeding trials that are primarily designed to market products to participating physicians. Published studies of these strategies are limited but suggest the risk of undue industry influence on physician prescribing behavior with little or no benefit to patient care. Many physicians may view drug representatives as useful, but reliance on individuals whose charge is to increase sales is not a satisfactory solution to practitioners' need for valid, reliable, and up-to-date medical information.

Several recent policy changes may affect the relationships between industry and physicians in practice. Several drug and device companies are voluntarily making public information on their payments to physicians by physician name and the purpose and the amount of the payment; other companies have been required to do so as part of legal agreements with federal prosecutors. The Pharmaceutical Research and Manufacturers of America also recently revised its code on interactions with health care professionals to prohibit the use of certain marketing tools and gifts (including well-paid speaking engagements) as inducements or rewards for prescribing or recommending a course of treatment. Compliance is voluntary, but the organization says that it will ask member companies to declare whether they have adopted its provisions and will then post the information on its website. The Advanced Medical Technology Association has included similar provisions in its revised code for medical device companies. In addition, some professional societies have recently revised their conflict of interest policies to restrict or manage certain relationships with industry and to make their policies public.

Taking into account the weight of the evidence and the recommendations and actions of other groups or institutions, the committee rec-

ommended the elimination of some problematic relationships between practicing physicians and industry. In broad terms, Recommendation 6.1 calls on physicians in clinical practice not to accept gifts, including meals, from companies; to enter only into bona fide consultation arrangements with written contracts; to avoid presenting or publishing material whose content is controlled by industry or is ghostwritten; to set restrictions on meetings with company sales representatives; and to use drug samples only for patients who lack financial access to medications. This recommendation is generally parallel to Recommendation 5.1 (for faculty, students, residents, and fellows). Independent assessment of the evidence and the practice of evidence-based medicine are core competencies for physicians in clinical practice as well as academic practice; relationships with industry should not undermine those competencies.

Because recommendations directed to physicians are more likely to be adopted if other incentives are aligned with those recommendations, Recommendation 6.1 also calls on professional societies and institutions that provide health care (and that employ physicians or grant them staff privileges) to take actions to support physician acceptance of changes in their relationships with companies. Recommendation 6.2 calls for further revisions to industry practices to be consistent with those outlined in Recommendation 6.1. It is a separate recommendation to emphasize that relationships between physicians and industry are bilateral and that the expectations for givers and receivers in financial relationships should be parallel.

CONFLICTS OF INTEREST AND DEVELOPMENT OF CLINICAL PRACTICE GUIDELINES

Financial relationships with companies affected by clinical practice guidelines are common both for groups convening expert panels to develop guidelines and for the individuals serving on those panels. Groups often do not make public their conflict of interest policies, their sources of funding for guideline development, or the financial relationships of the panel members. This lack of transparency makes it difficult for the readers and users of guidelines to assess the potential for undue influence and bias.

The committee found examples of alleged undue industry influence on the development of clinical practice guidelines but little systematic research. The risks that result from the acceptance of industry funding and the inclusion of individuals with industry ties on guideline development panels include possible bias in the recommendations made in guidelines and possible harm to patients because guidelines may influence physician practice behavior, quality improvement measures, reimbursement incentives, and insurance coverage decisions.

Recommendation 7.1 calls on groups that develop guidelines not to

accept direct funding for guideline development from industry and generally to exclude individuals with conflicts of interest from guideline development panels. Because it may be impossible in some situations to obtain the needed expertise from individuals who have no conflicts, the recommendation also includes measures to limit the likelihood of undue influence if panels include members with conflicts of interest. These measures include requiring that chairs of guideline development panels have no conflicts of interest, limiting members with conflicts of interest to a small minority of the panel membership, and precluding such members from voting on topics in which they have a financial interest. The committee also calls for groups that develop guidelines to involve the public in attempts to identify experts without conflicts of interest, to make such efforts public, and to disclose publicly any conflicts of interest of those selected for membership on panels.

Recommendation 7.2 calls for organizations that have an interest in the use of evidence-based clinical practice guidelines to establish incentives to encourage the developers of guidelines to adopt the committee's recommendations. For example, the National Guideline Clearinghouse could require that the guidelines that it posts include information about the sources of funding for a guideline, the sponsor's conflict of interest policy, and the financial interests of the expert panel members. Similarly, public and private health plans and accreditation and certification bodies could avoid the use of clinical practice guidelines that lack information that allows users to identify conflicts of interest and assess the risks that they pose.

INSTITUTIONAL CONFLICTS OF INTEREST

Institutional conflicts of interest arise when an institution's own financial interests or the interests of its senior officials pose risks to the integrity of the institution's primary interests and missions. Institutional conflicts typically appear when research conducted within an institution could affect the value of equity that the institution holds in a company or the value of a patent that the institution licenses to a company. Institutional conflicts of interest have not received as much attention as individual conflicts of interest, but their consequences can also be damaging. If they are not properly identified and managed, institutional conflicts can undermine the work and reputation of an entire institution, including employees or members who are themselves strictly avoiding individual conflicts of interest.

Recommendation 8.1 calls for the boards of trustees of institutions to establish a conflict of interest committee to make judgments about institutional relationships with industry, including the relationships of senior officials. In their fiduciary role, members of the board oversee the long-term interests of the institution. They stand at a greater distance from the

day-to-day pressures of decision making, which should help them assess more judiciously the potential risks posed by a particular financial interest to the institution's core missions. This committee of the board of trustees could be supported by staff committees on institutional conflict of interest. Recommendation 8.2 calls for NIH to develop regulations requiring institutions covered by the 1995 PHS regulations to adopt institutional conflict of interest policies.

THE ROLE OF SUPPORTING ORGANIZATIONS

In carrying out medical research and education, providing patient care, and developing practice guidelines, physicians, researchers, and the institutions in which they work are part of complex intersecting systems. These systems can amplify or mitigate the pressures that individuals and institutions may experience to expose their primary professional obligations or social missions to undue influence from secondary interests, such as financial gain. Within these systems, a variety of organizations—public and private—can influence the policies and practices of institutions and support the norms of professional integrity. For example, accreditation and certification organizations set standards for medical schools, residency and fellowship programs, and individual physicians. State agencies license and relicense individual physicians, and specialty boards certify and recertify them. Journals publish medical research. The National Guideline Clearinghouse posts clinical practice guidelines. Public and private health insurers use a variety of financial and other incentives to influence the practices of institutions and individual clinicians. The U.S. Department of Justice and the Office of the Inspector General of the U.S. Department of Health and Human Services enforce laws limiting or prohibiting certain conflicts of interest, and NIH is responsible for overseeing compliance with PHS policies covering its grantees.

In addition to discussing incentives for policy adoption and implementation, the final chapter of the report discusses the roles of collaboration and consensus building in building conflict of interest policies that win acceptance and avoid needless burdens. Although the emphasis should be on preventing problems, policies should also be backed by enforcement and appropriate sanctions as well as assessment of their effectiveness.

Recommendation 9.1 proposes that groups such as accrediting organizations, public and private health insurers, and associations of medical journal editors develop incentives to make institutions more accountable for preventing, identifying, and managing conflicts of interest. The accompanying discussion gives examples of such incentives. The final recommendation, Recommendation 9.2, calls for more research to assess the positive and negative consequences of conflict of interest policies and provide a

stronger evidence base for improving conflict of interest policies and their application.

Society has traditionally granted the medical profession considerable autonomy to regulate itself. Society may be willing to continue do so in the case of conflicts of interest; but concern is growing in the U.S. Congress, state legislatures, federal agencies, and elsewhere that stronger measures are needed. Physicians and researchers can play a vital role in designing responsible and reasonable conflict of interest policies and procedures that reduce the risks of bias and the loss of trust while avoiding undue burdens or even harms. They and the institutions that carry out medical research, education, clinical care, and practice guideline development must recognize public concerns about conflicts of interest and take effective measures soon to maintain public trust.

OVERVIEW AND LIST OF RECOMMENDATIONS

TABLE S-1 Report Recommendations in Overview

Recommendation Number and Topic	Primary Actors
General policy	
3.1 Adopt and implement conflict of interest policies	Institutions that carry out medical research and education, clinical care, and clinical practice guideline development
3.2 Strengthen disclosure policies	Institutions that carry out medical research and education, clinical care, and clinical practice guideline development
3.3 Standardize disclosure content and formats	Institutions that carry out medical research and education, clinical care, and clinical practice guideline development and other interested organizations (e.g., accrediting bodies, health insurers, consumer groups, and government agencies)
3.4 Create a national program for the reporting of company payments	U.S. Congress; pharmaceutical, medical device, and biotechnology companies
Medical research	
4.1 Restrict participation of researchers with conflicts of interest in research with human participants	Academic medical centers and other research institutions; medical researchers

TABLE S-1 Continued

Recommendation Number and Topic	Primary Actors
Medical education	
5.1 Reform relationships with industry in medical education	Academic medical centers and teaching hospitals; faculty, students, residents, and fellows
5.2 Provide education on conflict of interest	Academic medical centers and teaching hospitals; professional societies
5.3 Reform financing system for continuing medical education	Organizations that created the accrediting program for continuing medical education and other organizations interested in high-quality, objective education
Medical practice	
6.1 Reform financial relationships with industry for community physicians	Community physicians; professional societies; hospitals and other health care providers
6.2 Reform industry interactions with physicians	Pharmaceutical, medical device, and biotechnology companies
Clinical practice guidelines	
7.1 Restrict industry funding and conflicts in clinical practice guideline development	Institutions that develop clinical practice guidelines
7.2 Create incentives for reducing conflicts in clinical practice guideline development	Accrediting and certification bodies, formulary committees, health insurers, public agencies, and other organizations with an interest in objective, evidence-based clinical practice guidelines
Institutional conflict of interest policies	
8.1 Create board-level responsibility for institutional conflicts of interest	Institutions that carry out medical research and education, clinical care, and clinical practice guideline development
8.2 Revise PHS regulations to require policies on institutional conflicts of interest	NIH
Supporting organizations	
9.1 Provide additional incentives for institutions to adopt and implement policies	Oversight bodies and other groups that have a strong interest in or reliance on medical research, education, clinical care, and practice guideline development
9.2 Develop research agenda on conflict of interest	NIH, Agency for Healthcare Research and Quality, and other agencies of the U.S. Department of Health and Human Services

RECOMMENDATION 3.1 Institutions that carry out medical research, medical education, clinical care, or practice guideline development should adopt, implement, and make public conflict of interest policies for individuals that are consistent with the other recommendations in this report. To manage identified conflicts of interest and monitor the implementation of management recommendations, institutions should create a conflict of interest committee. That committee should use a full range of management tools, as appropriate, including elimination of the conflicting financial interest, prohibition or restriction of involvement of the individual with a conflict of interest in the activity related to the conflict, and providing additional disclosures of the conflict of interest.

RECOMMENDATION 3.2 As part of their conflict of interest policies, institutions should require individuals covered by their policies, including senior institutional officials, to disclose financial relationships with pharmaceutical, medical device, and biotechnology companies to the institution on an annual basis and when an individual's situation changes significantly. The policies should

- request disclosures that are sufficiently specific and comprehensive (with no minimum dollar threshold) to allow others to assess the severity of the conflicts;
- avoid unnecessary administrative burdens on individuals making disclosures; and
- require further disclosure, as appropriate, for example, to the conflict of interest committee, the institutional review board, and the contracts and grants office.

RECOMMENDATION 3.3 National organizations that represent academic medical centers, other health care providers, and physicians and researchers should convene a broad-based consensus development process to establish a standard content, a standard format, and standard procedures for the disclosure of financial relationships with industry.

RECOMMENDATION 3.4 The U.S. Congress should create a national program that requires pharmaceutical, medical device, and biotechnology companies and their foundations to publicly report payments to physicians and other prescribers, biomedical researchers, health care institutions, professional societies, patient advocacy and disease-specific groups, providers of continuing medical education, and foundations created by any of these entities. Until the Congress acts, companies should voluntarily adopt such reporting.

RECOMMENDATION 4.1 Academic medical centers and other research institutions should establish a policy that individuals generally may not conduct research with human participants if they have a significant financial interest in an existing or potential product or a company that could be affected by the outcome of the research. Exceptions to the policy should be made public and should be permitted only if the conflict of interest committee (a) determines that an individual's participation is essential for the conduct of the research and (b) establishes an effective mechanism for managing the conflict and protecting the integrity of the research.

RECOMMENDATION 5.1 For all faculty, students, residents, and fellows and for all associated training sites, academic medical centers and teaching hospitals should adopt and implement policies that prohibit

- the acceptance of items of material value from pharmaceutical, medical device, and biotechnology companies, except in specified situations;
- educational presentations or scientific publications that are controlled by industry or that contain substantial portions written by someone who is not identified as an author or who is not properly acknowledged;
- consulting arrangements that are not based on written contracts for expert services to be paid for at fair market value;
- access by drug and medical device sales representatives, except by faculty invitation, in accordance with institutional policies, in certain specified situations for training, patient safety, or the evaluation of medical devices; and
- the use of drug samples, except in specified situations for patients who lack financial access to medications.

Until their institutions adopt these recommendations, faculty and trainees at academic medical centers and teaching hospitals should voluntarily adopt them as standards for their own conduct.

RECOMMENDATION 5.2 Academic medical centers and teaching hospitals should educate faculty, medical students, and residents on how to avoid or manage conflicts of interest and relationships with pharmaceutical and medical device industry representatives. Accrediting organizations should develop standards that require formal education on these topics.

RECOMMENDATION 5.3 A new system of funding accredited continuing medical education should be developed that is free of industry influence, enhances public trust in the integrity of the system, and provides high-quality education. A consensus development process that includes representatives of the member organizations that created the accrediting body for con-

tinuing medical education, members of the public, and representatives of organizations such as certification boards that rely on continuing medical education should be convened to propose within 24 months of the publication of this report a funding system that will meet these goals.

RECOMMENDATION 6.1 Physicians, wherever their site of clinical practice, should

- not accept of items of material value from pharmaceutical, medical device, and biotechnology companies except when a transaction involves payment at fair market value for a legitimate service;
- not make educational presentations or publish scientific articles that are controlled by industry or contain substantial portions written by someone who is not identified as an author or who is not properly acknowledged;
- not enter into consulting arrangements unless they are based on written contracts for expert services to be paid for at fair market value;
- not meet with pharmaceutical and medical device sales representatives except by documented appointment and at the physician's express invitation; and
- not accept drug samples except in certain situations for patients who lack financial access to medications.

Professional societies should amend their policies and codes of professional conduct to support these recommendations. Health care providers should establish policies for their employees and medical staff that are consistent with these recommendations.

RECOMMENDATION 6.2 Pharmaceutical, medical device, and biotechnology companies and their company foundations should have policies and practices against providing physicians with gifts, meals, drug samples (except for use by patients who lack financial access to medications), or other similar items of material value and against asking physicians to be authors of ghostwritten materials. Consulting arrangements should be for necessary services, documented in written contracts, and paid for at fair market value. Companies should not involve physicians and patients in marketing projects that are presented as clinical research.

RECOMMENDATION 7.1 Groups that develop clinical practice guidelines should generally exclude as panel members individuals with conflicts of interest and should not accept direct funding for clinical practice guideline development from medical product companies or company foundations. Groups should publicly disclose with each guideline their conflict of

interest policies and procedures and the sources and amounts of indirect or direct funding received for development of the guideline. In the exceptional situation in which avoidance of panel members with conflicts of interest is impossible because of the critical need for their expertise, then groups should

- publicly document that they made a good-faith effort to find experts without conflicts of interest by issuing a public call for members and other recruitment measures;
- appoint a chair without a conflict of interest;
- limit members with conflicting interests to a distinct minority of the panel;
- exclude individuals who have a fiduciary or promotional relationship with a company that makes a product that may be affected by the guidelines;
- exclude panel members with conflicts from deliberating, drafting, or voting on specific recommendations; and
- publicly disclose the relevant conflicts of interest of panel members.

RECOMMENDATION 7.2 Accrediting and certification bodies, health insurers, public agencies, and other similar organizations should encourage institutions that develop clinical practice guidelines to adopt conflict of interest policies consistent with the recommendations in this report. Three desirable steps are for

- journals to require that all clinical practice guidelines accepted for publication describe (or provide an Internet link to) the developer's conflict of interest policies, the sources and amounts of funding for the guideline, and the relevant financial interests of guideline panel members, if any;
- the National Guideline Clearinghouse to require that all clinical practice guidelines accepted for posting describe (or provide an Internet link to) the developer's conflict of interest policies, the sources and amounts of funding for development of the guideline, and the relevant financial interests of guideline panel members, if any; and
- accrediting and certification organizations, public and private health plans, and similar groups to avoid using clinical practice guidelines for performance measures, coverage decisions, and similar purposes if the guideline developers do not follow the practices recommended in this report.

RECOMMENDATION 8.1 The boards of trustees or the equivalent governing bodies of institutions engaged in medical research, medical education, patient care, or practice guideline development should establish their

own standing committees on institutional conflicts of interest. These standing committees should

- have no members who themselves have conflicts of interest relevant to the activities of the institution;
- include at least one member who is not a member of the board or an employee or officer of the institution and who has some relevant expertise;
- create, as needed, administrative arrangements for the day-to-day oversight and management of institutional conflicts of interest, including those involving senior officials; and
- submit an annual report to the full board, which should be made public but in which the necessary modifications have been made to protect confidential information.

RECOMMENDATION 8.2 The National Institutes of Health should develop rules governing institutional conflicts of interest for research institutions covered by current U.S. Public Health Service regulations. The rules should require the reporting of identified institutional conflicts of interest and the steps that have been taken to eliminate or manage such conflicts.

RECOMMENDATION 9.1 Accreditation and certification bodies, private health insurers, government agencies, and similar organizations should develop incentives to promote the adoption and effective implementation of conflict of interest policies by institutions engaged in medical research, medical education, clinical care, or practice guideline development. In developing the incentives, these organizations should involve the individuals and the institutions that would be affected.

RECOMMENDATION 9.2 To strengthen the evidence base for the design and application of conflict of interest policies, the U.S. Department of Health and Human Services should coordinate the development and funding of a research agenda to study the impact of conflicts of interest on the quality of medical research, education, and practice and on practice guideline development and to examine the positive and negative effects of conflict of interest policies on these outcomes.

1

Introduction

Patients and the public benefit from constructive collaboration between academic medicine and pharmaceutical, medical device, and biotechnology companies. At the same time, medical leaders, public officials, public interest groups, and others have raised concerns about the risks associated with the extensive financial ties that link industry with the individuals and institutions that carry out medical research, medical education, patient care, and practice guideline development. The risks are that individual and institutional financial interests may unduly influence professional judgments involving these primary institutional missions. Such conflicts of interest threaten the integrity of scientific investigations, the objectivity of medical education, the quality of patient care, and the public's trust in medicine.

The benefits of collaboration with industry are most evident in biomedical research. New medications and medical devices have significantly improved outcomes for people with a range of serious and common diseases, including—among many others—coronary artery disease, congestive heart failure, hypercholesterolemia, several types of cancers, and peptic ulcer disease. Such successful products result from a long, complex, and often unpredictable process of translating basic science discoveries into new preventive, diagnostic, or therapeutic products and services. The basic discoveries often come from the laboratories of university and government scientists; but their development into actual products available to clinicians and patients usually depends on the technical, production, and financial resources of pharmaceutical, medical device, or biotechnology companies. It is estimated that it takes an average of 15 years and more than $800 million to discover and develop a new drug, and only about 10 percent of the drugs that enter clinical testing are actually approved for marketing (DiMasi et al., 2003, 2004; FDA, 2004a). Chapter 4 and Appendix E

further examine the nature and value of university-industry collaboration in medical research.

With the benefits of research collaboration and the expansion of financial relationships in other areas have also come conflicts of interest and evidence of bias. For example, in clinical research, unfavorable results in some major industry-sponsored trials have been withheld from publication, thus distorting the totality of the findings included in the scientific literature. These trials involved drugs commonly prescribed for arthritis, depression, and elevated cholesterol levels, among other medications (Wright et al., 2001; Gibson, 2004; Whittington et al., 2004; Kastelein et al., 2008). Not publishing negative results undermines evidence-based medicine and puts millions of patients at risk for using ineffective or unsafe drugs. One striking case involves the withholding of negative findings from pediatric clinical trials of the effects of selective serotonin reuptake inhibitors on depression (Healy, 2006; Turner et al., 2008). Findings were withheld so frequently that although one meta-analysis of the published literature (ACN, 2004) concluded that these drugs were safe and effective, another meta-analysis (Whittington et al., 2004) that took into account unpublished as well as published data concluded the opposite: that the risks outweigh the benefits for all but one drug in this class of antidepressants. A recent analysis found that more than half of the trials used to support Food and Drug Administration approval for the marketing of a drug or medical device had not been published within 5 years after approval (Lee et al., 2008). In addition, litigation has revealed documents that link bias in publications to financial relationships with pharmaceutical manufacturers (Steinman et al., 2006; Psaty and Kronmal, 2008; Ross et al., 2008). As discussed in Chapter 4, the statistical associations involving industry sponsorship do not prove causality, but they do raise serious concerns about undue industry influence and have prompted a range of responses, including the creation of publication protections in university-industry research contracts and the issuance of regulations and other requirements that the results of clinical trials be reported in clinical trial registries.

In medical education, it is particularly troublesome when a faculty member is a promotional speaker for a pharmaceutical, medical device, or biotechnology company or agrees to be listed as an author for a ghostwritten publication. This is because faculty members are expected to present unbiased information and objective assessments of the scientific literature and to help medical students, residents, and fellows develop life-long habits of exercising independent judgment and critically evaluating scientific evidence. They are also expected to serve as role models of professionalism. These expectations may be undermined by some financial relationships between faculty and industry and by failures to disclose such relationships.

In clinical care, patients need to trust that their physicians' recommen-

dations are not distorted by commercial interests. Such trust may contribute to the healing process and to patients' sense of well-being. Some financial relationships between physicians and industry raise concerns about the risk of bias in clinical decisions. For example, companies have paid some physicians large but generally undisclosed amounts to give talks to other physicians, whose prescribing practices were then tracked by company sales representatives (Elliott, 2006; Carlat, 2007). Drug samples and other gifts to physicians by company sales representatives are major marketing tools that evidence suggests influence prescribing choices (see Chapter 5). Furthermore, during the last decade, several federal prosecutions alleging that companies made illegal payments to physicians to induce them to use the companies' drugs or medical devices have led to settlements in which the companies agreed to modify various marketing practices and, in some cases, to post publicly their payments to physicians (see Chapter 6). The prevalence of illegal payments is not known.

Another area of concern is clinical practice guidelines. Clinical practice guidelines influence patient care, quality and performance standards, and reimbursement for health care professionals and institutions. If a risk exists that guidelines are biased or may be viewed as biased in favor of the products of the companies that sponsored the guideline development process or companies that have financial relationships with experts involved in the process, then patients may be harmed and users' trust in the guidelines may be undermined. Evaluating the potential for such bias is often difficult, however, because many entities that develop practice guidelines do not have clear conflict of interest policies for this activity, do not disclose their funding sources, and do not reveal the relevant financial relationships or conflicts of interest for the experts responsible for developing a set of guidelines. A review of clinical practice guidelines that do include information on financial relationships of the participants suggests that conflicts of interest are common (for examples, see Chapter 7 and guidelines posted on the website for the National Guideline Clearinghouse).

Conflicting interests are, to some degree, both ubiquitous and difficult to avoid. For example, regardless of how they are paid for their services (e.g., on a fee-for-service or a capitated basis), physicians will face some incentives that may at times conflict with their professional responsibility to provide care that best serves their patients' interests. Medical school faculty may face conflicts in the time and energy that they devote to each element of their academic responsibilities—research, teaching, and clinical care.

Many conflicts are unavoidable features of multifaceted professional roles and obligations. Others are optional, for example, the creation of a consulting or a speaking agreement with a pharmaceutical, medical device, or biotechnology company. These kinds of financial relationships with industry are the focus of this report.

As explained further in Chapter 2, this report specifically defines a conflict of interest as existing when an individual or institution has a secondary interest (e.g., an ownership interest in a start-up biotechnology company) that creates a risk of undue influence on decisions or actions affecting a primary interest (e.g., the conduct of objective and trustworthy medical research). This definition frames a conflict of interest in terms of the risk of such undue influence and not the actual occurrence of bias.

Some argue that concerns about conflicts of interest are overstated and that policy responses have been excessive, inconsistent, and unduly burdensome on physicians and researchers (see, e.g., Stossel [2005, 2007], Duvall [2006], Borgert [2007], and Bailey [2008]). According to that viewpoint, problems related to conflicts of interests are rare. Thus, the vast majority of scientists, educators, and clinicians should not be subject to onerous conflict of interest rules and regulations because of a few miscreants. The argument continues that burdensome rules and regulations stifle valuable collaborations between industry and academia. Moreover, allegations of conflict of interest inappropriately call into question the motives and integrity of individual scientists and clinicians, because a financial relationship related to one's research, teaching, or clinical practice does not prove the actual presence of bias in decisions or judgments. Consequently, it would be better to focus on detecting and minimizing bias rather than on disclosing, limiting, or managing financial relationships with industry. Furthermore, some of the intended beneficiaries of conflict of interest policies—for example, research participants—do not seem to be concerned about the financial interests of the investigators (see, e.g., Hampson et al. [2006] and Weinfurt et al. [2006a] and the further discussions in Chapters 3 and 4). Another criticism is that the focus on conflicts of interest related to financial ties with industry distracts attention from other threats to objectivity and public trust, such as career ambitions, a desire for recognition, intellectual bias, personal ties, and physician payment methods.

As discussed in Chapter 2, many objections to conflict of interest policies are based on misunderstandings of their purpose and nature. If they are correctly explained, the policies should not be seen as impugning anyone's motives. They are, in fact, a way of avoiding intrusive investigations into people's motives. They also protect against bias or distrust when other methods (e.g., assessments of actual bias after the fact) are not feasible or sufficient. Although other secondary interests may inappropriately influence professional decisions and additional safeguards are necessary to protect against bias from such interests, financial interests are more readily identified and regulated.

Opposition to conflict of interest policies often focuses on what might be lost with further restrictions on ties to industry. For example, eliminating industry support for accredited continuing medical education might

result in increases in the fees that physicians must pay for such education, a reduction in the number of accredited courses, and a drop in income for institutions that provide continuing medical education. To cite another example, if universities insist on contract terms that restrict a company's ability to withhold or censor research findings, then companies might move more research contracts elsewhere (e.g., to contract research organizations or overseas research centers that do not have such restrictions). Similarly, some faculty members may leave a university if that university restricts faculty members' financial ties with industry. Such losses (costs) tend to be immediate, easily identifiable, and tangible.

In contrast, the costs of conflicts of interest and the benefits of mitigating or eliminating them tend to be less tangible, less immediate, and more diffuse. Eliminating direct industry funding of continuing medical education, for example, could increase evidence-based physician prescribing practices, which over time could reduce wasteful health care spending and improve the quality of patient care, but demonstrating such causal relationships could be difficult or impossible. Another benefit of dealing with conflicts of interest that is even harder to define and document but that is significant could be the maintenance of public trust in medical professionals and institutions. Indeed, the maintenance of trust is a major objective of conflict of interest policies across a broad range of professions, in addition to medicine (see Appendix C).

Research suggests that people are generally not good at making trade-offs between costs and benefits that are immediate and tangible and those that are less immediate and less tangible (for a review, see Rick and Loewenstein [2008]). People tend to put a disproportionate emphasis on costs and benefits that are immediate and tangible. For example, the impact of a single, free drug company-sponsored lunch on a physician's prescribing practices or on public trust may be small to insignificant, but the cumulative consequences of many lunches to many physicians may be great. The human tendency to overweight the immediate and tangible compared with the delayed and intangible thus complicates efforts to understand and respond to conflicts of interest.

OVERVIEW AND THEMES OF REPORT

This Institute of Medicine (IOM) report examines the extent of financial relationships with industry and conflicts of interest in medical research, education, and practice and in the development of clinical practice guidelines. It reviews policies that have been adopted or proposed to avoid or manage these conflicts and recommends steps that can be taken to improve the design, implementation, and evaluation of these policies. The report builds on the analyses and recommendations of other groups. It is different,

however, in its focus on conflict of interest across the spectrum of medicine and in its identification of overarching issues and strategies that can be used to limit the negative effects of conflicts of interest while preserving the benefits of collaboration with industry, particularly in moving discoveries from basic science into improved patient care. The report has several broad messages.

1. The goal of conflict of interest policies in medicine is to protect the integrity of professional judgment and to preserve public trust rather than to try to remediate problems with bias or mistrust after they occur.

In all aspects of medicine, judgments must inevitably be made, and reasonable people will disagree over some judgments. Both science and medicine depend on public trust that judgments are made in good faith and are not unduly influenced by the financial interests of professionals or the institutions with which they are affiliated. Well-formulated and well-explained conflict of interest policies can help identify individual and institutional relationships that could reasonably be questioned and allow judgments to be made prospectively about whether particular relationships should be eliminated, permitted, or managed.

It is prudent to require physicians and medical researchers to avoid or manage situations that offer a significant possibility of bias rather than to wait to investigate allegations of bias or misconduct until after they occur. Investigations performed to uncover bias after the fact can be difficult, time-consuming, and heavily burdensome for all involved. Furthermore, when bias occurs in clinical research, medical education, or practice guideline development, it can harm research participants or patients, waste scarce resources, and damage individual and institutional reputations, including the reputations of those whose relationships with industry are appropriately structured and disclosed and serve the public good. If trust is eroded by continuing revelations of withheld negative research findings, promotional relationships disguised as consulting services, and similarly troublesome situations, it may be hard to restore.

2. Disclosure of individual and institutional financial relationships is a critical but limited first step in the process of identifying and responding to conflicts of interest.

Institutions that carry out medical research, medical education, patient care, and practice guideline development depend on individuals' disclosure of their financial relationships with industry. Without such disclosure, institutions will lack the information they need to identify and assess conflicts of interest and determine what additional steps—such as eliminating or managing the conflicting interest—may be necessary. Disclosure by institutions is likewise important because institutions may also have financial relationships that create conflicts of interest. The disclosures need to be sufficiently specific and comprehensive to allow an initial assessment of the

risk of undue influence. At the same time, the harmonization of disclosure requirements and procedures can reduce administrative burdens for researchers and physicians who must make multiple disclosures to different institutions for different purposes.

Disclosure does not resolve or eliminate conflicts of interest. Institutions must also evaluate and act upon the disclosed information. Actions might include the elimination of a relationship, further disclosure (e.g., to research participants, patients, or the public), or other types of management (e.g., restricting the participation of a researcher with a conflict of interest in the enrollment of study participants or analysis of study data).

3. Conflict of interest guidelines and policies can be strengthened by engaging physicians, researchers, and medical institutions in developing policies and consensus standards.

For conflict of interest policies to be truly effective, buy-in from physicians and researchers will be important, so that they regard conflict of interest policies as a means to help them fulfill their professional responsibilities and not as externally imposed nuisances. Furthermore, if those who are subject to conflict of interest policies participate in policy development, they may suggest how the policies can be framed to avoid unintended adverse consequences and undue administrative burdens. In several areas in which substantial policy variation or disagreement exists and greater agreement is needed, the report proposes the creation of consensus development panels with a broad range of participants, including consumer representatives. Two areas that are ripe for consensus building involve the standardization of information that physicians and researchers are required to disclose (Chapter 3) and the development of a new system of financing continuing medical education (Chapter 5).

4. A range of organizations—public and private—can promote the adoption and implementation of conflict of interest policies and help create a culture of accountability that sustains professional norms and promotes public confidence in professional judgments.

Institutions that carry out medical research, medical education, clinical care, and practice guideline development have the primary responsibility for addressing conflicts of interests in these activities. These institutions do not, however, act in isolation. Rather, they interact with many other organizations—including academic and trade membership associations, accreditation and certification bodies, patient advocacy groups, health plans, and federal and state agencies—that have a stake in reducing the severity of individual and institutional conflicts of interest. As discussed in Chapter 9, these organizations can create incentives to encourage institutions to adopt and implement policies that are consistent with the recommendations of this committee and other organizations, such as the Association of American Medical Colleges, the Association of American Universities, and the International Committee of Medical Journal Editors. Such incentives would

encourage and reinforce professional responsibility and promote public trust.

5. Research on conflicts of interest and conflict of interest policies can provide a stronger evidence base for policy design and implementation.

The current evidence base for conflict of interest policies is not strong. A program of research on conflicts of interest and conflict of interest policies could provide policy makers with a better evidence base and a basis for understanding the nature and consequences of conflicts of interest in different situations. It could likewise guide policy makers as they revise policies and procedures to make them more effective and less burdensome.

6. If medical institutions do not act voluntarily to strengthen their conflict of interest policies and procedures, the pressure for external regulation is likely to increase.

The continuing publicity about conflicts of interest in medicine and the failure of individuals and institutions to adhere to conflict of interest policies has prompted calls for government regulation. Indeed, this report recommends some areas for government action, but it also emphasizes that risks as well as the potential benefits of regulation should be considered.

Origins of the Study

This study grew out of discussions within the IOM about the threats to objectivity and public trust in biomedical research and medicine created by conflicts of interest related to certain types of financial relationships between industry and researchers based in universities and federal agencies. Consideration of the topic was further stimulated by inquiries from groups outside the IOM about whether the IOM would examine conflicts of interest and industry ties as they might affect the publication of research and the development of clinical practice guidelines. In response, the IOM proposed a broad-ranging study that would examine conflicts of interest across medical research, medical education, clinical practice, and practice guideline development.

The IOM appointed a 17-member committee to oversee the study and develop the study report. (See Appendix A for more information about study-related activities.) Consistent with its charge, the committee

- examined financial relationships with industry and conflicts of interest in medical research, education, practice, and practice guideline development and
- developed analyses and recommendations to inform the design and implementation of policies for the identification and management of

conflicts of interest in these contexts without damaging constructive collaborations with industry.

To address this broad charge, the committee consciously adopted a crosscutting perspective and tried to view medicine as a complex system with many interacting components and interested parties. It drafted its report for a diverse audience of academic, scientific, professional, medical institution, industry, consumer, news media, and government leaders. Their understanding of the hazards of conflicts of interest and the elements of effective, balanced policies aimed at preventing conflicts of interest from occurring is essential.

During the course of its work, the committee searched for and assessed empirical evidence relevant to its charge, and it read and heard a wide range of views. The analyses and recommendations in this report reflect the committee's conscientious effort to understand and take these views into account. The committee also examined how conflicts of interest are handled in other professions (see Appendix C).

Focus and Concepts

Given the breadth of its charge, the committee focused on conflicts of interest involving *physicians, biomedical researchers, and senior institutional officials*. These individuals have been at the center of most controversies about conflicts of interest and most proposals for policy change. Many of the conclusions and recommendations presented in this report will, however, be generally relevant to nursing, pharmacy, dentistry, and other health professions and to other health researchers. In some cases, institutional policies may extend beyond researchers, professionals, and senior officials. For example, professional society policies governing members of a panel developing clinical practice guidelines will cover all members, including consumers, patients, and the representatives of health insurers.

This report generally uses the term *institutions* to refer to academic medical centers; professional societies; patient or consumer groups; and other entities that carry out medical research, provide medical education and clinical care, or develop clinical practice guidelines.[1] The report also distinguishes (particularly in Chapter 9) supporting *organizations*, such as accrediting agencies and state licensure boards, that may create incentives

[1] For the purposes of this report, the committee distinguished companies that produce commercial medical products from other mostly noncommercial medical institutions (and their personnel) that these companies seek to influence. (Some providers of continuing medical education are for-profit concerns.) The committee recognized that commercial companies conduct or sponsor research and may undertake activities with educational value.

for institutions to adopt and implement effective and credible conflict of interest policies or codes of conduct and for individuals to follow these policies or codes. Some entities, such as medical journals, cross these definitional boundaries and are covered by recommendations related to both institutions and organizations.

Reflecting the discussions that led to this study and the emphasis of much research, press coverage, and public and professional debate, this report emphasizes *financial interests and relationships* involving *pharmaceutical, medical device, and biotechnology companies* that make—or that are developing—medical products used in patient care. (For convenience, the report sometimes refers to these companies as "industry" or "medical product companies," although some start-up biotechnology and other companies may not yet have products approved for marketing.) Other interests, such as the desire for public recognition, may also threaten objectivity and public trust, but financial interests are the central focus of conflict of interest debates and policies.

Notwithstanding the prominence of medical product companies in discussions of conflicts of interest in medicine, the committee recognized that significant conflicts of interest in medical research, education, and practice can be created by financial relationships involving many other kinds of companies. These include health insurers; prescription drug and other benefit management companies; law firms; investment companies; and suppliers of food, office supplies, and other nonmedical goods and services. Much of the discussion in this report about the adoption of policies and the disclosure of information should be relevant to financial relationships involving these other commercial entities.

The committee also understood that serious conflicts of interest may arise from the way in which physicians are paid for their clinical services and from physician ownership interests in hospitals, diagnostic centers, and facilities. The IOM did not plan this study to investigate these issues, but they are briefly discussed in Chapter 6.

Although the analyses presented in this report build on a series of reports on responsible research and integrity in science issued by the IOM and the National Research Council, those earlier reports did not examine conflict of interest in depth. Nonetheless, they provide useful perspectives. In particular, the reports *Integrity in Scientific Research* (IOM/NRC, 2002) and *Responsible Research* (IOM, 2003) underscore the importance of creating organizational and social environments that support and encourage responsible and ethical behavior by individuals and institutions. This report also builds on recommendations made in other reports that called for the undertaking of more and better comparative effectiveness studies and other steps needed to build and communicate the evidence base for clinical practice (see, e.g., previous IOM studies [1991, 2007]). One recommendation

of this report (Recommendation 9.2) is that the evidence base for conflict of interest policies needs to be strengthened to help policy makers identify effective policies and avoid unwanted consequences.

HISTORICAL AND POLICY CONTEXT

Concerns about conflicts of interest have a long history; and the responses to these conflicts have evolved as relationships with industry in medical research, education, and practice have grown more frequent and more complex. They have also evolved as different responses to such relationships have been tried and found to be in need of modification.

The following brief review indicates, first, that both government regulations and voluntary codes of conduct often follow the discovery of instances of questionable or inappropriate relationships and conduct. This is similar to the pattern in other areas, such as the oversight of research involving human participants.[2] Second, government scrutiny of conflicts of interest may stimulate private, voluntary efforts by academic and other institutions to deal with problems and avoid regulation. Third, when these efforts are found to be wanting and government acts, legislators and administrators may still delegate to regulated institutions many of the details of policy development, implementation, and monitoring.

Expanding Relationships Between Industry and Medicine

Relationships between physicians, medical researchers, and medical schools and companies that produce medical products have a long history, as have efforts to encourage such relationships. For example, in the early 1920s, Eli Lilly worked with researchers at the University of Toronto to manufacture insulin in quantities adequate for research and then clinical use; the university also granted royalty-free patents to other companies to expand the drug's availability worldwide (Thayer, 2005). In 1925, the National Research Council (which the National Academy of Sciences established at the request of President Woodrow Wilson to organize scientific research) created a short-lived National Research Fund that raised money from private companies to support research in academic institutions (Swann, 1988).

The mixing of product marketing and medical information for physicians likewise has a lengthy history (see, e.g., Podolsky and Greene [2008]).

[2] In general, this report follows the practice of recent IOM reports in referring to research participants rather than research subjects (IOM, 2001, 2003, 2004; NBAC, 2001). This report uses the latter terminology when quoting and sometimes when referring to reports that employ that terminology.

More than a century ago, a review in the *Chicago Medical Recorder* of *Merck's Manual of the Materia Medica* (now the *Merck Manual of Diagnosis and Therapy*) observed: "[a]lthough this little book is gotten out by a manufacturing firm and with some view towards its advertising value, it nonetheless is of such merit that it is deserving of mention in this column" (quoted by Lane and Berkow [1999, p. 112]). Then, as now, recognition of the value of industry contributions can coexist with unease about commercial motivations and potential bias.

Professional societies and the medical products industry also have longstanding relationships, for example, industry advertising in journals sponsored by medical societies. As early as the late 1940s and early 1950s, the American Medical Association (AMA) began to market information from its new physician database to pharmaceutical companies and to commission studies of the effectiveness of different marketing techniques, the results of which were sent to pharmaceutical and device companies—along with pamphlets promoting advertising in the *Journal of the American Medical Association* (Greene, 2007). This AMA business has generated some controversy and is discussed further in Chapter 6 (see also Steinbrook [2006]).

Biomedical research saw a marked expansion of government funding after World War II. By 1965, spending by the National Institutes of Health (NIH) and other federal agencies accounted for almost two-thirds of the total funding for biomedical research, whereas it was about 7 percent in 1940 (Ginzberg and Dutka, 1989). Then, in the late 1970s, the balance began to shift toward commercial funding. By the turn of the 21st century, the share of health research and development funding accounted for by industry reached 55 to 60 percent (see Chapter 4). New relationships and collaborations between universities and industry during the late 1970s and 1980s were stimulated by a combination of economic conditions, pressures on the federal budget, scientific discoveries, needs for expertise outside universities, and other factors, including legislative incentives for universities to develop discoveries commercially. A Congressional Research Service report noted that another factor in universities' pursuit of industry funding was a "desire to lessen the regulations associated with the expenditure of Federal dollars" (Johnson, 1982, p. 2).

Industry has also become a major source of funding for medical education, particularly continuing medical education. Between 1998 and 2007, the share of continuing medical education provider income accounted for by commercial sources, excluding advertising and exhibits, grew from 34 to 48 percent, with higher rates for some providers, such as for-profit education and communication companies and medical schools (ACCME, 2008a). Through their support for professional society journals and meetings, pharmaceutical and medical device companies are also important sources of

income for professional societies, often accounting for 30 to 50 percent or more of the total income of professional societies (see Chapter 8).

Growing Concerns About Relationships with Industry

As they have evolved, relationships between industry and medicine have brought many benefits, primarily in biomedical research. They have also raised concerns that such relationships can—if they are not properly managed—threaten the objectivity of medical research, education, and practice and undermine public trust in critical American institutions.

Table 1-1 lists some notable events in the emergence of relationships with industry and conflict of interest as a concern in medicine. They include congressional hearings in the 1980s that posed questions about whether conflicts of interest were reducing openness in universities and biasing the advice given to policy makers. A Congressional Research Service report on the commercialization of academic biotechnology research observed that "the credibility of university scientists associated with industry has fallen into question" (Johnson, 1982, p. 5). An article in *Science* from the same period titled The Academic-Industrial Complex (Culliton, 1982) summarized the ethical concerns that these relationships presented to university administrators and faculty:

> How can universities preserve open communication and independence in the direction of basic research while also meeting obligations to industry? Is it acceptable for one corporation to dominate research in an entire department? Are there adverse consequences in terms of collaboration among faculty in various departments if one group must worry about protecting corporate rights to licenses? Will patent and licensing provisions delay scientific publication? Should corporate sponsorship be subject to peer review? Under what conditions may a faculty member have an equity position in industry? Do such ties compromise loyalty to university teaching and research? Will graduate students be compromised or poorly served? Will extensive corporate ties erode public confidence in university faculty as disinterested seekers of truth? (Culliton, 1982, p. 961)

Concerns about conflict of interest beyond the research context were also growing during the 1970s and 1980s. Some concerns related to questions about commercial bias in scientific publications. Others focused on physician referral of patients to specialty centers in which they had a financial interest and on the prevalence of company-provided gifts, lavish entertainment, marketing activities that were disguised as scientific information, and other relationships in both community and academic medical settings.

TABLE 1-1 Timeline of Selected Events Relevant to the Evolution of Conflict of Interest Principles, Policies, and Practices

Year	Event
1959	Senator Estes Kefauver initiates hearings on pricing practices in the pharmaceutical industry that expand to cover marketing practices
1962	President John F. Kennedy issues a memorandum, Preventing Conflict of Interest on the Part of Advisers and Consultants to the Government (27 FR 1341)
1964	American Association of University Professors and American Council on Education (ACE) issue a statement on conflicts of interest in government-sponsored research
1971	The National Academy of Sciences (NAS) approves a letter (On Potential Sources of Bias) to ask members of its study committees to describe financial and other factors that in their judgment "others may deem prejudicial"
1972	The U.S. Congress passes the first antikickback statute (P.L. 92-603)
1978	The U.S. Congress enacts the Ethics in Government Act (P.L. 95-521) to promote confidence in the integrity of government officials and prevent conflict of interest
1980	Patent and Trademark Amendments of 1980 (P.L. 96-517) (Bayh-Dole Act) and Stevenson-Wydler Technology Innovation Act (P.L. 96-480) encourage the commercial development of federally developed or funded technologies
1981	Economic Recovery Tax Act of 1981 (P.L. 97-34) provides a 25 percent tax credit for 65 percent of private investments in universities for basic research
1982	U.S. House of Representatives holds hearings on university-industry cooperation in biotechnology
	The presidents of five leading universities meet with scientists and industry leaders to discuss conflict of interest and university-industry ties (Pajaro Dunes Conference)
1983	California Fair Political Practices Commission orders an investigation of the University of California's enforcement of rules on disclosure of corporate support of faculty research after finding that more than 50 faculty members had financial interests in companies that were funding their research
1984	Association of American Universities (AAU) conducts a survey of university policies on conflict of interest in privately funded research
	Editorial in the *New England Journal of Medicine* announces policy on conflict of interest
1985	AAU issues the report *University Policies on Conflict of Interest and Delay of Publication*
1986	ACE issues the report *Higher Education and Research Entrepreneurship: Conflicts Among Interests*
1987	U.S. Public Health Services (PHS) issues Grants Policy Statement, which states that grant recipients should have written guidelines on conflict of interest
	Accreditation Council for Continuing Medical Education (ACCME) adopts Guidelines for Commercial Support (revised and issued as standards in 1992)
1988	U.S. House of Representatives holds hearing on scientific misconduct and hears concerns about conflicts of interest. Additional hearings follow (one is titled Is Science for Sale?)

TABLE 1-1 Continued

Year	Event
	International Committee of Medical Journal Editors (ICMJE) develops a statement of requirements for authors that includes a provision for authors to voluntarily disclose relevant financial interests and expands the scope of the policy in 1993 and 1998
1989	The U.S. Congress passes a law (Omnibus Budget Reconciliation Act of 1989) barring self-referral arrangements for clinical laboratory services under Medicare; legislation passed in 1993 and 2004 expands and refines the restrictions
	Ethics Reform Act of 1989 (P.L. 101-94) allows federal advisory committee members (special government employees) to participate, despite a conflict of interest, if an agency determines that the need for the individual to participate outweighs the conflict
	The National Institutes of Health (NIH) issues and then withdraws draft guidelines on policies on conflict of interest for recipients of PHS research grants
1990	A U.S. House Committee on Government Operations report (*Are Scientific Misconduct and Conflicts of Interest Hazardous to Our Health?*) recommends the development of PHS regulations that "clearly restrict financial ties for researchers who conduct evaluations of a product or treatment in which they have a vested interest"
	Association of American Medical Colleges publishes *Guidelines for Dealing with Faculty Conflicts of Commitment and Conflicts of Interest in Research*
	American Medical Association (AMA) adopts statement on inappropriate gifts to physicians from industry
	American College of Physicians issues a position paper on physicians and the pharmaceutical industry
1992	NAS report *Responsible Science* (1992) concludes, "The issues associated with conflict of interest in the academic research environment are sufficiently problematic that they deserve thorough study and analysis by major academic and scientific organizations" (p. 78)
1993	ICMJE approves statement on conflict of interest in peer review and publication
	Minnesota law limits drug company gifts to physicians and requires company disclosure of payments to physicians (excluding drug samples and educational materials)
1994	The National Science Foundation (NSF) issues Investigator Financial Disclosure Policy "to help ensure the appropriate management of actual or potential conflicts" (effective 1995)
1995	PHS (60 FR 35815, 42 CFR 50) publishes regulations on the responsibility of grant applicants for promoting objectivity in research
1998	The Food and Drug Administration publishes regulations requiring disclosure by clinical investigators of certain financial relationships (63 FR 5233)
1999	The death of Jesse Gelsinger in a gene transfer experiment provokes controversy after it is revealed that the principal investigator and his university had ownership interests in the company making the interventional product

See Table 1-2 for reports issued after 1999

Continued

TABLE 1-1 Continued

Year	Event
2001	ICMJE publishes new, more stringent policies on conflict of interest
	Vermont requires pharmaceutical companies to disclose payments to doctors and certain health care organizations related to marketing activities
	To promote adherence to its ethical guidelines, AMA, with funding from industry, initiates the campaign "What you should know about gifts to physicians from industry"
2003	HHS issues Compliance Program Guidance for Pharmaceutical Manufacturers, which observes that gifts "potentially implicate the anti-kickback statute if any one purpose of the arrangement is to generate business for the pharmaceutical company"
2004	The U.S. Congress questions NIH about the apparent failure of dozens of employees to disclose relationships with industry
	NIH issues stringent new policies for employees and later moderates them
	HHS issues final guidance to institutional review boards on financial relationships in clinical trials
	ACCME issues revised Standards for Commercial Support
2007	The U.S. Department of Justice announces deferred prosecution or nonprosecution agreements that allow five orthopedic device companies to avoid criminal prosecution for providing financial inducements for surgeons to use their products
2008	The Pharmaceutical Research and Manufacturers of America releases revised *Code on Interactions with Healthcare Professionals* and recommends an end to some gift-giving practices
	The Advanced Medical Technology Association issues revised *Code of Ethics*
	HHS issues regulations requiring physician-owned hospitals and physician owners of hospitals to disclose physician ownership interest to patients
	Massachusetts limits gifts and payments to physicians from pharmaceutical and device companies and requires companies to publicly disclose certain payments
2009	Federal legislation proposed to require disclosure of company payments to physicians and others and reporting of physician ownership interests in health care facilities

(2007), Emanuel and Thompson (2008), ORI (2008), Lopes (2009), MedPAC, (2009), and Carpenter (in press).

Evolving Public and Private Responses to Concerns About Conflict of Interest

In the early 1960s, in recognition of the importance of outside advice on complex scientific and policy questions from objective experts, the fed-

eral government (through a presidential memo) established policies to limit conflicts of interest among special government employees serving as advisory committee members and consultants. In the academic community, the American Association of University Professors (AAUP) and the American Council on Education (ACE) issued a joint statement, On Preventing Conflicts of Interest in Government-Sponsored Research at Universities (AAUP/ACE, 1965). The statement spoke of the importance of university-industry relationships but stressed the need to protect the integrity of educational institutions in the face of ties between these institutions and both government and industry. It called for universities to advise government research agencies about the steps they were taking to avoid problems. According to McNeil and Roberts (1991), this statement forestalled government regulation and led to the adoption of policies by most major research universities of "very general guidelines" on conflict of interest that relied on faculty-initiated disclosure (p. 149). By 1967, a number of universities, including Yale, Harvard, Stanford, Michigan, Chicago, Minnesota, and California, had adopted conflict of interest policies that had been approved by the Federal Office of Science and Technology (Wellman, 1967).

A few years after AAUP and ACE issued their statement and after some incidents that raised concerns about bias and conflict of interest, the National Academy of Sciences approved a letter, On Potential Sources of Bias, which it issued in 1971. The letter asked members of the organization's scientific study committees to describe financial and other factors that in their judgment "others may deem prejudicial" (quoted in Parascandola [2007]). According to Parascandola, "[s]cientists universally opposed the policy, however, for a range of reasons—while some argued that all experienced and knowledgeable experts were inherently conflicted, others were offended at the suggestion that any expert could be biased" (p. 3774).

Such negatives responses to conflict of interest policies continue. Nonetheless, the adoption of policies has expanded as the scope and complexity of relationships with industry have increased and instances of questionable or illegal behavior have accumulated—with the attendant negative publicity.

In 1984, the Association of American Universities declined to propose conflict of interest policies for its members, but it did undertake a survey of university policies (OTA, 1984; McNeil and Roberts, 1991). It found that 19 of the 46 responding institutions relied on faculty members to determine whether they had a possible conflict of interest and then to initiate disclosure; 26 institutions had a university-initiated, annual disclosure process (reported in Maatz [1992]). In addition, 21 schools had policies on faculty equity or managerial ties to industry that required disclosure and approval.

In what appears to be the first policy of its sort, the editor of the *New*

England Journal of Medicine announced in 1984 that the journal would ask authors to disclose their relationships with companies that could be affected by their published findings (Relman, 1984). By 1990, the Association of American Medical Colleges had issued for its members guidelines on dealing with conflicts of interest, and AMA had provided guidance to physicians on accepting gifts from industry.

Congressional concerns about financial relationships between physicians or researchers and commercial entities have led to legislation on several occasions and also to threats of legislation. As early as 1972, the U.S. Congress prohibited companies from offering and physicians and others from accepting overt or covert payments or other rewards in return for the referral of patients or ordering of services paid for by Medicare or Medicaid. Beginning in 1989, the Congress also enacted a series of restrictions (known as the "Stark laws," after their sponsor) on self-referral arrangements, which occur when physicians refer patients to specialty hospitals, imaging centers, or other facilities in which they have a financial interest. Also, in 1989, congressional hearings and other pressures prompted NIH to issue draft guidelines on conflict of interest for its grantees. The agency then withdrew these guidelines after criticism that they were too restrictive and would "devastate productive relationships between university researchers and industry, deny scientists outlets for their discoveries at the bench and interfere with the technology transfer" (Mazzaschi, 1990, p. 137). The U.S. Public Health Service eventually issued regulations in 1995 (see Appendix B).

In recent years, members of Congress have raised questions about industry support for continuing medical education, industry payments to physicians, and faculty member disclosure of such payments. As discussed in later chapters, members of Congress have proposed legislation that addresses some of these questions. Some proposals would require companies to report consulting and other payments to physicians, and other proposals promote alternatives to pharmaceutical company sales representatives as sources of information for physicians about medications.[3] A few states have adopted policies requiring companies to disclose certain payments to physicians, and some states have created alternative education programs for physicians and other prescribers of medications.

In the 1990s, social science research techniques and findings began to influence understandings of the relationships between physicians and

[3] Examples of legislation that was proposed but not enacted by the 110th Congress (2007-2008) include S. 2029 (Physician Payments Sunshine Act of 2007), S. 3343 (Medicare Imaging Disclosure Sunshine Act of 2008), and H.R. 6752 (Independent Drug Education and Outreach Act of 2008). The first proposal has been revised and reintroduced in the 111th Congress (Grassley, 2009).

industry. For example, in an analysis of marketing literature and interactions between physicians and industry representatives, Roughead and colleagues (1998) noted that "[r]eciprocity is one of the norms by which society abides. . . . The provision of gifts by sales personnel encourages an automatic response of indebtedness on the part of the receiver who will then look for ways to make repayment" (p. 307). Other research has documented the importance of unconscious bias (see Appendix D).

Since 2000, a number of private and public groups have issued reports on conflict of interest in aspects of medical research, education, or practice. Table 1-2 lists some of the more prominent reports, several of which are discussed in later chapters of this report. Most reports have focused on research. Most have recognized the value of legitimate and properly designed research, educational, and technical relationships; but several have recommended some restrictions on other types of relationships and the more effective implementation of policies. In addition, the Pharmaceutical Research and Manufacturers of America (PhRMA) revised its voluntary *Code on Interactions with Healthcare Professionals* (effective January 2009) to more strongly discourage noninformational gifts, such as providing tickets to sporting events and token consulting arrangements (PhRMA, 2008). The Advanced Medical Technology Association has also revised its *Code of Ethics* for medical device manufacturers (effective July 2009) to include generally similar provisions (AdvaMed, 2008). (Other countries also have industry codes on relationships between the pharmaceutical industry and physicians [Jost, 2009].)

The recommendations in the reports listed in Table 1-2 are often similar (but not entirely consistent) in calling for more accountability and openness and more effective implementation. The policies of particular institutions vary, and some individuals may be subject to multiple policies that apply to their different roles and activities. To the extent that the adoption and implementation of policy recommendations have been evaluated, the results are mixed, as discussed in Chapter 3.

Evolution of Other Strategies to Limit Bias in Medical Research, Education, and Practice

At the same time that policy makers, universities, professional groups, and others were responding to concerns about conflict of interest, methodologists, statisticians, and scientists were working to develop and refine methods for designing and conducting research and analyzing data in ways that limit bias—whatever the source—during all stages of scientific investigation, from protocol design through the reporting of the results (see Chapter 4). In addition, academic medical centers have instituted education on evidence-based medicine to instruct future physicians on how to evaluate

TABLE 1-2 Selected Reports on Conflict of Interest Released Since 2000

Date	Organization	**Title of Report or Paper**
2001	Association of American Medical Colleges	*Protecting Subjects, Preserving Trust, Promoting Progress: Policy and Guidelines for the Oversight of Individual Financial Interests in Human Subjects Research*
2001	Association of American Universities	*Report on Individual and Institutional Financial Conflict of Interest*
2001	General Accounting Office	*Biomedical Research: HHS Direction Needed to Address Financial Conflicts of Interest*
2001	National Bioethics Advisory Commission	*Ethical and Policy Issues in Research Involving Human Participants*, Volume 1 (see the subsection on conflict of interest in Chapter 3)

critically the evidence presented in (or absent from) journal articles, practice guidelines, and other sources of clinical information and advice (see, e.g., Bennett et al. [1987] and EBM Working Group [1992]). Others have worked to shift methods for the development of clinical practice guidelines away from unsystematic expert opinion and consensus processes toward formal, objective procedures for identifying and reviewing the relevant evidence and linking the strength and quality of the evidence to recommendations (see Chapter 7). These techniques and strategies work together with conflict of interest policies to reduce the risk of bias and maintain public trust in medical research, education, and practice.

ORGANIZATION OF REPORT

Chapter 2 sets forth a normative and conceptual framework for the report, including definitions and the criteria used to assess the potential benefits and harms created by financial relationships. Chapter 3 presents an overview of conflict of interest policies and what is known about their impact.

Chapters 4 through 7 are devoted to examinations of industry relationships and conflicts of interest in the domains of medical research, medical education, clinical practice, and practice guideline development, respectively. Chapter 8 discusses the importance of policies on conflicts that arise at the level of the institution. Finally, Chapter 9 discusses the role that accrediting and other supporting organizations can play in promoting the adoption and implementation of conflict of interest policies by the institutions that are on the front lines of medical education, research, and practice. Several appendixes provide additional background about the report or topics mentioned in the report.

2

Principles for Identifying and Assessing Conflicts of Interest

Relationships between physicians and biomedical researchers on the one hand and pharmaceutical, medical device, and biotechnology companies on the other hand are widespread and have produced important benefits, particularly in the development of new tests and treatments. At the same time, these relationships have also created significant risks that the financial goals of industry may conflict with the professional goals of medicine. The goals of for-profit medical companies are to produce products that improve health and, at the same time, to ensure a financial return to shareholders. The primary goals of medicine include improving health by providing beneficial care to patients, conducting valid research, and offering excellent medical education. In pursuing those goals, individual professionals, health care institutions, and research organizations have obligations to put patient interests first, carry out unbiased research, critically appraise information, and serve as role models of professional behavior for students. The problem of conflict of interest arises because in some circumstances in modern medicine these goals and obligations are at risk of being compromised by the undue pursuit of financial gain or other secondary interests.

Medicine today faces many difficult challenges, including, among others, high costs of treatment and associated pressures to cut costs, lack of availability of health insurance, and persistent medical errors. In comparison, the problem of conflict of interest may seem less significant. However, none of the other challenges can be adequately met if conflicts of interest are not well managed. For example, patients and the public need to be able to trust that the high costs of health care and health insurance arise from the provision of services that are beneficial, necessary, appropriately priced, and not inappropriately driven by the financial interests of physicians, other health care providers, or medical product companies. Failure to deal

with the problem of conflict of interest can undermine efforts to address the other serious challenges that medical professionals and researchers face today.

This chapter develops a conceptual framework for identifying and assessing conflicts of interests.[1] In addition to defining the concept of conflict of interest and clarifying some common misunderstandings about its applications, the chapter presents principles to guide the formulation and implementation of conflict of interest policies. The principles take the form of (1) statements of the purposes of conflict of interest policies, (2) criteria for assessing the content of these policies, and (3) criteria for evaluating the implementation of policies. The principles do not directly yield decisions in particular cases or even rules that could be directly enforced, nor do they determine in advance the relative importance of all the values involved in making decisions. In applying them to particular policies and individual cases, there is no substitute for judicious practical judgment sensitive to the institutional context. However, the principles provide an essential framework for formulating and implementing any conflict of interest policy. They focus attention on the most important factors that should be considered when professionals and institutions make decisions and policies regarding conflicts of interest, select the agents who should be responsible for implementing and enforcing those policies, and choose the methods that they will use to regulate conflicts of interest.

WHAT IS A CONFLICT OF INTEREST?

Although conflict of interest policies are now widespread in many areas of medicine, the meaning and purposes of these policies are not always clearly understood. The term "conflict of interest" is used in many different and often inconsistent ways. Nonetheless, institutional and public policies on conflicts of interest need to define what the policies cover and what they do not cover.

The definition that the committee adopted is consistent with the core meaning of the concept as it is used in many institutional policies. It is, however, formulated to clarify key elements that are sometimes obscured in discussions of those policies.

[1] The discussion in this chapter draws on work by Thompson (1993) and Emanuel and Thompson (2008). The committee also consulted other definitions and frameworks, including those of Davis (1998), AAMC (2001), Davis and Stark (2001), NIH (2004), Moore et al. (2005), Lurie (2007), Sage (2007), AAMC-AAU (2008), and Beauchamp and Childress (2009).

> *A conflict of interest is a set of circumstances that creates a risk that professional judgment or actions regarding a primary interest will be unduly influenced by a secondary interest.*

To avoid common misunderstandings of the concept that can lead to misplaced and ultimately ineffective or counterproductive policies, the committee stresses the importance of each of the three main elements of a conflict of interest: the primary interest, the secondary interest, and the conflict itself.

The primary interest that conflict of interest policies seek to protect varies according to the purpose of a professional activity. Primary interests include promoting and protecting the integrity of research, the welfare of patients, and the quality of medical education. Physicians and medical researchers accept the primacy of these interests when they act in their professional roles. Physicians and researchers exercise judgment and discretion in their work. Patients, the public, research participants, medical students, residents, and fellows need to trust physicians and researchers to act and make judgments in ways that are consistent with these primary interests. These primary interests are sometimes stated as ends or goals (e.g., promoting patient welfare), as obligations (e.g., the physician's obligation to promote patient welfare), or as rights (e.g., the patient's right to have the doctor promote his or her welfare). The committee uses the term primary "interests" to encompass all of these values, however they are stated. Whatever the primary interests are, the point of regulating conflicts of interest is to try to ensure that secondary interests do not subvert physicians' and researchers' decisions and actions regarding those primary interests and do not undermine trust in their clinical or scientific judgment. Furthermore, medical institutions—including medical schools, research institutes, professional societies, scientific journals, patient advocacy organizations, or government health agencies—should also keep these primary interests paramount, as discussed further in Chapter 8.

To be sure, identification of the exact primary interest in specific situations may sometimes be challenging, and primary interests sometimes conflict with each other. For example, in public health emergencies or under conditions of dire resource scarcity, physicians may have fundamental obligations to the population as a whole that may compete with their obligations to individual patients. In clinical research, the welfare of the participants in a study and the study's successful completion may be in conflict. Nonetheless, it is almost always clear that a primary interest should take precedence over a secondary interest.

The second main element of a conflict of interest is the secondary interest. Secondary interests may include not only financial gain but also the desire for professional advancement, recognition for personal achievement,

and favors to friends and family or to students and colleagues. Conflict of interest policies typically and reasonably focus on financial gain and financial relationships. The reason is not that financial gains are necessarily more corrupting than the other interests but that they are relatively more objective, fungible, and quantifiable. A financial interest therefore tends to be more effectively and fairly regulated than other secondary interests. Furthermore, for-profit companies exert influence primarily through their financial relationships with physicians and researchers. They cannot bestow professional rewards such as prestigious scientific prizes that may also lead to conflicts of interest.

Most secondary interests, including financial interests, are—within limits—legitimate and even desirable goals. The secondary interests are objectionable only when they have greater weight than the primary interest in professional decision making. For example, for a researcher or a teacher, financial interests should be subordinate to presenting scientific evidence in an unbiased manner in publications and presentations.

A financial interest does not have to be great for the influence to be undue. Indeed, social science research suggests that gifts of small value may influence decisions (see Appendix D). It also suggests that influence may operate without an individual being conscious of it. When a secondary interest has inappropriate weight in a decision and distorts the pursuit of a primary interest, it is exerting undue influence.

The third key element of the definition is the conflict itself. It is not an occurrence in which primary interests are necessarily compromised but, rather, a set of circumstances or relationships that create or increase the risk that the primary interests will be neglected as a result of the pursuit of secondary interests. A conflict of interest exists whether or not a particular individual or institution is actually influenced by the secondary interest. The claim that a conflict of interest exists is based on common experience and social science research. Both experience and research indicate that under certain conditions there is a risk that professional judgment may be influenced more by secondary interests than by primary interests.

Some of these elements of a conflict of interest refer to degrees or quantities (e.g., more or less influence), but they are not directly quantifiable. What counts as undue is a matter of judgment and depends on the context. It is not a numerical probability but a judgment in a particular situation about whether a risk is undue or inappropriate. The standards for making such a judgment should be transparent and clearly specified in actual policies rather than in vague statements that professionals should avoid "undue influence." Subsequent chapters examine what situations or relationships may be considered inappropriate in research, patient care, medical education, and practice guideline development. Appendix C offers perspectives on conflicts of interest in other professions.

Conflicts of interest should be distinguished from other closely related conflicts. Not all conflicts in medicine are conflicts between a primary and a secondary interest. A conflict of obligation arises when an individual or institution has duties that require different actions but only one of these actions can be taken in the given circumstance. Dilemmas in medical ethics often take this form, that is, the need to make hard choices between two values, neither one of which is clearly superior to the other. A common example is maintaining the confidentiality of a patient with a contagious disease, which may conflict with preventing that patient from harming someone else. There is no conflict of interest in this example because both interests have plausible claims to be considered primary. Conflicts of obligation are essentially conflicts among different primary interests. Both obligations or interests are legitimate, often equally so, and it cannot be said in advance which one should take priority.

Conflicts of commitment are closer to conflicts of interest. They often involve a conflict between what institutions view as employees' primary responsibilities to the institution and the employees' outside commitments, such as voluntary community service, participation in a political campaign, or teaching or conducting research for another institution. Like conflicts between primary interests, conflicts of commitment involve two perfectly respectable activities (indeed, in some cases, identical activities, except that they are conducted at different institutions). Also, like conflicts of interest, the institution can legitimately claim in advance that one activity takes priority over the other if they come into conflict in any way. The concern is not usually about the risk of undue influence over specific decisions (e.g., the prescribing of a particular medication or the reporting of research findings). Rather, the concern is about time and effort, for example, whether individuals are devoting sufficient attention to their responsibilities within their own primary institution. Conflicts of interest and conflicts of commitment are sometimes covered in the same institutional policy; but the circumstances, risks, and evaluative frameworks are sufficiently different that they warrant separate consideration. Nevertheless, it makes sense for the policies to be covered in the same documents and information resources and to be administered by the same officials and committees.

WHAT ARE THE PURPOSES OF CONFLICT OF INTEREST POLICIES?

Institutions, professional organizations, and governments establish policies to address the problem of conflict of interest on behalf of the public. Conflict of interest policies are attempts to ensure that professional decisions are made on the basis of primary interests and not secondary interests. (See the discussion of the policies of other professions in Appendix C.)

As discussed further in Chapter 9, such policies work best when they are preventive and corrective rather than punitive. To the extent that they are effective, they serve two overarching purposes: maintaining the integrity of professional judgment and sustaining public confidence in that judgment. That professionals should promote these purposes constitutes the fundamental principle underlying any respectable conflict of interest policy.

First, the most obvious way in which the integrity of professional judgment can be compromised is through bias. Other practices can also undermine that integrity when they violate standards of professional conduct, such as the failure to publish research findings in a timely manner, the failure to treat students and postdoctoral fellows fairly, and a lack of openness with patients. Conflict of interest policies seek to minimize the influence of secondary interests in all these practices. They most significantly guard against the risk that financial interests will have excessive weight in decisions about the conduct of research, teaching, the provision of patient care, and the development of practice guidelines.

Such policies do not assume that any particular professional will necessarily let financial gain influence his or her judgment, nor do they imply that the individual researcher or physician is an unethical person. They assume only that under some conditions a risk exists that the decisions may be unduly influenced by considerations that should be irrelevant. Nonetheless, physicians and researchers are sometimes offended by assertions that they have conflicts of interest, believing that such assertions impugn their ethical integrity.

To avoid what they believe to be the negative connotations of "conflict of interest," some institutions use such phrases as "relationships with industry" or "financial relationships" to describe not only relationships that may be evaluated for the presence of potential conflicts but also relationships that are judged to be conflicts of interest. This less direct language has the effect of obscuring the serious risks that conflicts pose. Such language is not necessary if it is recognized that the determination that an individual or institution has a conflict of interest is a judgment about the situation and not about the professional who happens to be in that situation.

The second purpose of conflict of interest policies—to help sustain public confidence in professional judgment—is less appreciated but no less important. Here the goal is to minimize conditions that would cause reasonable individuals to suspect that professional judgment has been improperly influenced by secondary interests, whether or not it has. The public includes not only patients and research subjects but also editorial writers and journalists, officials at nonprofit foundations, public officials, and other opinion leaders. When or if the public and public officials distrust physicians, researchers, or educators, they are likely to seek greater government

regulation, withhold funding, and take other steps that could jeopardize future programs of patient care, research, or education.

When a physician, researcher, or educator acts in ways that lead to distrust, the consequences may affect colleagues, patients, students, and the institution or profession as a whole. Similarly, institutional practices can be the source of distrust, and the effects of such distrust may be even more widespread and damaging than distrust of an individual. Physicians retain a high standing with the public compared with the standing of many other professional groups; but physicians should be vigilant, because once public confidence is undermined, it may be difficult to restore.

As discussed in Appendix C, other professions—law, accounting, engineering, and architecture—have also recognized the importance of conflict of interest policies and ethical codes to promote objectivity in decision making and sustain public confidence. In some recent cases, most notably, accounting, failure to adhere to these codes has led to increased government regulation.

WHY NOT EXAMINE THE MOTIVES OF THE DECISION MAKER OR THE VALIDITY OF THE DECISION?

Individuals accused of having a conflict of interest often say that they would never let financial interests influence their decisions. This objection to conflict of interest policies misses the point. Because (as noted above) the conflict is a set of circumstances or conditions involving a risk rather than a specific individual decision, the existence of a conflict of interest does not imply that any individual is improperly motivated. Nevertheless, an individual professional might still object that it is not fair to generalize in this way. He or she may want to say: "Look at my actual decisions and consider my distinguished reputation." However, conflict of interest policies are by their nature designed to avoid the need to investigate individual cases in this way. For at least two reasons, such policies do not focus on the motives in a particular case.

First, reliably ascertaining or inferring motives in this context is usually impossible for those assessing whether a relationship constitutes a conflict of interest. Generally, medical research, patient care, and education involve multiple considerations and many small judgments and decisions that are impractical to review; and even if they were reviewed, they would likely not yield a clear picture of the underlying motivation. Thus, readers of journal articles, medical students, patients, and conflict of interest committees are not in a good position to judge whether secondary interests motivated a decision. The motives behind institutional decisions are usually even more opaque.

Second, any thorough effort to determine motivation in a particular case would be improperly intrusive and highly time-consuming. Fair hearings could not be held and reliable conclusions could not be reached without risking violation of the rights of privacy of the many individuals who might be involved and without distracting many people from other important work.

Sometimes another, closely related objection to a claim that an individual has a conflict of interest is raised. This objection accepts that motives should not be considered but denies the relevance of the conditions under which decisions are made: "Judge my decision—the results of the research, the content of the lecture, the prescription of the drug—and not my financial interests." Here again the problem is that many people affected by professional decisions are not in a position to judge the validity of those decisions. In addition, those who are competent to judge may not be able to do so until after the damage has occurred. Furthermore, the argument for judging outcomes ignores one of the two main purposes of conflict of interest policies: the maintenance of public confidence. Even valid decisions and research may not be widely accepted as such if they occur under conditions in which secondary interests are prominent. Moreover, many decisions in research and clinical care are close calls. Plausible reasons can be cited for each of several alternative choices. The decisive factor in whether a judgment or an action is accepted as valid may turn on whether a researcher or a clinician can be trusted to be acting for the sake of scientific truth and the best interests of patients.

Because it is both intrusive and usually impracticable to investigate motives and because the competent and timely appraisal of decisions is often difficult, it may be tempting to conclude that patients, the public, and researchers simply need to trust physicians. Trust is important, but generalized trust and reliance that medical professionals act in accord with primary professional interests may be difficult to maintain in the face of evidence that this trust is sometimes abused. Furthermore, creating trust in medical professionals who conduct research or develop practice guidelines is hard because they have little or no contact with many of the people who are affected by their decisions and who have only limited knowledge with which to evaluate the decisions. Trust is necessary and desirable, but it must be based on reasonable expectations. Those who rely on professionals must have good reason to trust their decisions. In short, they need assurance that the professionals are trustworthy. Policies designed to reduce conflicts of interest and mitigate their impact provide an important foundation for public confidence in medical professionals and institutions.

SHOULD POLICIES ALSO REQUIRE THAT PROFESSIONALS AVOID THE "APPEARANCE OF CONFLICT OF INTEREST"?

Some conflict of interest policies refer to actual or perceived conflicts of interest and state that professionals should avoid "even the appearance of a conflict of interest." That requirement may lead to confusion. All conflicts of interest involve perceptions or appearances because they are specified from the perspective of people who do not have sufficient information with which to assess the actual motives of a decision maker and the effects of those motives on the decisions themselves.

Policies that contrast actual and perceived conflicts of interest give rise to two problems. First, the contrast suggests that there is no conflict (only an appearance of a conflict) unless the decision maker actually favors secondary interests over primary interests. The implication, then, is that conflict of interest policies should treat a perceived conflict as less serious than an actual conflict. However, when a professional's judgment is actually distorted by the acceptance of a gift or the prospect of influencing a stock in which the professional has an interest, the violation is no longer principally a conflict of interest but becomes a different kind of offense, one that may involve malpractice, scientific misconduct, or kickbacks. Those violations call for the use of procedures quite different from those on which conflict of interest policies should concentrate.

Second, the creation of a category of perceived conflicts, as distinct from actual conflicts, opens the door to overly broad and excessively subjective rules. If perceived conflicts are treated as different from the other (so-called actual) conflicts that the policy regulates, conduct that is perfectly proper can be unfairly called into question. With a loose notion of the perception or the appearance of a conflict of interest, circumstances that are suspicious only to uninformed people or predisposed reporters can be the basis of indiscriminate charges of conflicts of interest. Charges of conflicts of interest should be limited to circumstances specified by policies that are objectively grounded in past experience and reasonably interpreted on the basis of relevant and accessible information.

HOW CAN CONFLICTS OF INTEREST BE ASSESSED?

Conflicts are not binary; that is, they are not simply either present or absent. They can be more or less severe. The severity of a conflict depends on (1) the likelihood that professional decisions made under the relevant circumstances would be unduly influenced by a secondary interest and (2) the seriousness of the harm or wrong that could result from such influence. As discussed later in this chapter, the criterion of proportionality in conflict of interest policies provides that the expected benefits of a relationship may

TABLE 2-1 Criteria for Assessing the Severity of Conflicts of Interest

Likelihood of undue influence
- What is the value of the secondary interest?
- What is the scope of the relationship?
- What is the extent of discretion?

Seriousness of possible harm
- What is the value of the primary interest?
- What is the scope of the consequences?
- What is the extent of accountability?

be considered, and conflicts of interest may be allowed to continue if those benefits outweigh the risks and safeguards that are instituted.

Table 2-1 lists the questions that need to be asked when the severity of a conflict of interest is assessed in particular cases. These questions express criteria or principles that identify the most important factors to be considered in formulating policies and making decisions about conflicts of interest. Assessments of the likelihood of undue influence and the seriousness of the consequences usually reflect general judgments about situations—on the basis of experience—rather than evaluations of the character of the individual in question. The individual's behavior in similar situations in the past might, however, be taken into account. The next two sections discuss the criteria in more depth.

Assessing the Likelihood of Undue Influence

In assessing the likelihood of undue influence, it is reasonable to assume that the greater that the value of the secondary interest is (e.g., the greater that the size of the financial gain is), the more probable is its influence. Thus, equity or other ownership interests in a small biotechnology company have great potential for an increase in value on the basis of the results of a clinical trial (as well as the potential for no value). Large fees for serving on a company advisory board are more valuable than occasional small honoraria for talks. Although absolute value is important, the secondary interest should generally be measured in relation to the typical income for the relevant class of professionals or in relation to the value of a research project, institutional budget, or medical practice.

However, the monetary value of a secondary interest is not the only appropriate measure of its potential impact. The economic value of pens, inexpensive meals, and other nominal gifts or relationships is low; but as explained in Appendix D, small gifts may help to create and sustain relationships, for example, between a physician and a pharmaceutical company

and its representatives. The influence of such gifts and relationships may be subtle and the individual receiving such gifts may not even be conscious of their influence. It may therefore be necessary to manage or prohibit conflicts of interest even when the value of the secondary interest, as measured only by monetary value, is low and the likelihood of harm or wrong in a single instance is low.

Other aspects of relationships besides their dollar value may also increase their general value and therefore the risk of a conflict of interest. For example, payments that augment the income of an individual professional may create more concern than those that exclusively support the academic activities of a whole institution. A consulting arrangement that increases a researcher's income will tend to create more concern than one in which payments are made to the institution, department, or research group as a whole and disbursed under institutional oversight. Similarly, a research contract that is reviewed by a university for consistency with policies on data access, sponsor review, and publication rights will generally create less risk of a conflict of interest than a consulting arrangement that does not receive such review or that is reported only in very general terms (e.g., as involving payments over $20,000 when the actual amount is $200,000).

A second factor affecting the likelihood of undue influence is the scope of a relationship, which refers to its duration and depth. Longer and closer associations increase the scope and therefore the risk. Examples of such associations include a multiyear consulting agreement, a continuing leadership position as a member of a company board, or the weekly or monthly provision of free lunches at a physician's office. Likewise, long-term funding of a university or commercial continuing medical education program has more potential for influence than a one-time grant. Similarly, serving on a company's scientific advisory board, which more intimately ties the professional to the company over time, is more likely to affect the professional's judgment than accepting a fee for speaking about a company-sponsored research project.

The extent of discretion, that is, how much latitude a professional enjoys in making important decisions, is also pertinent. Even though some of their judgments are subject to various kinds of review, the principal investigator in a clinical trial exercises considerable discretion over innumerable, wide-ranging, and often hidden decisions, for example, decisions regarding the eligibility of patients to enter the clinical trial, determinations of clinical end points, ascribing of adverse events to the study intervention, the type of statistical analyses to be used, and the reporting of the results. This discretion is often limited by an independent oversight body, for example, a data and safety monitoring board, an independent panel that adjudicates adverse events, a medical monitor of adverse events, or an external auditor for data collection at individual research sites. Such oversight is usually

required for any clinical trials whose results will be presented to the Food and Drug Administration for regulatory approval of a drug or medical device. In assessing such limits on discretion, it is also important to consider the independence of the judgment of the members of any oversight body. Furthermore, the more closely that the research and data analysis methods follow standard methods, the less room there is for improper influence. Similarly, the more conventional the subject matter of educational presentations, the less scope there is for bias that is not easily detected.

Authority and discretion often vary by role. Principal investigators can influence multiple dimensions of a research project, whereas laboratory technicians or research assistants have less scope for influence in most situations. Deans and chancellors, through their power to control appointments, promotions, salaries, and space, wield great power, although they are typically several steps removed from conducting research projects or teaching courses. At the other extreme, most administrative staff members have little power to influence a university's research or teaching mission.

Assessing the Seriousness of Possible Harm

The starting point in assessing the seriousness of possible harm from a conflict of interest is to identify or specify the value of the primary interest. This report concentrates on the primary goals of medicine, particularly patient care, research, and medical education. Assessing the severity of a conflict requires an examination of the specific primary goal or goals at risk in a particular situation.

A second consideration is the scope of the consequences. The greater that the scope is, the more serious is the potential for harm. Conflicts of interest that may affect multiple patient care decisions have a large scope. For example, practice guidelines that set standards of care and criteria for insurance coverage may affect millions of patients. The results of a clinical trial for a common condition can affect how thousands of physicians prescribe a specific medication. Results from a pivotal trial of a novel type of therapy that may dramatically alter patient care are likely to have a larger scope than other trials that will influence care only at the margins. Thus, conflicts of interest in clinical trials deserve special attention because of the potentially large scope of their effects.

A conflict of interest may also have negative effects on an individual's colleagues or institution. Such effects need to be taken into account even if they do not occur frequently. A pharmaceutical or medical device company's sponsorship of a research project could raise questions about the work of other researchers in the institution and weaken their ability to raise funds from other sources. A professor's close connections with a company not only could raise doubts about the objectivity of his class materials and

presentations, but these connections could also have negative effects on the careers of his teaching assistants and the collegial culture of the institution. In view of such possible consequences, the fact that an individual has a right to engage in an activity should not be allowed to obscure the equally important fact that his or her actions may affect the rights of colleagues and students. The claim of an individual right by a professional does not preclude the possibility that this right may be regulated.

Finally, the seriousness of the possible harm depends in part on the extent of accountability. In general, a conflict of interest is more serious when the level of accountability of the physician, researcher, or educator to his or her peers, institution, licensing board, or similar entity is less extensive. If accountability for decisions is bolstered by an independent review of those decisions by colleagues or other authorities, there is generally less potential for harm and less cause for concern. However, the reviewers must be and must be viewed as being effective and independent and must have no conflicts of interest of their own. Accountability is also greater to the extent that sanctions for serious violations of policies are significant and imposed in a timely fashion, and it is further enhanced if the results of the disciplinary proceedings are regularly disclosed.

In summary, an overall assessment of whether a financial relationship constitutes a conflict of interest and, if so, how severe it is and how it should be managed depends on several considerations: the importance of the financial or other relationship for furthering primary medical values, the likelihood and seriousness of possible harm to those primary values, and the availability of measures that can reduce the likelihood or severity of harm. Chapter 3 discusses such measures and also the procedures applied by universities and other institutions to identify, limit, and manage conflicts of interest.

HOW CAN CONFLICT OF INTEREST POLICIES BE EVALUATED?

The discussion above focused on several questions and factors that should be considered in assessing the severity of a conflict of interest in financial relationships. They are intended to provide guidance for the formulation of the content of policies for controlling conflict of interest, for example, the specification of the information needed from individuals that will be sufficient to evaluate financial relationships, assess the severity of conflicts of interest, and guide responses to identified conflicts. Additional criteria are needed to evaluate the implementation or actual operation of the policies (Table 2-2). Even if policies are well formulated, they must also be well administered.

TABLE 2-2 Criteria for Evaluating Conflict of Interest Policies

Criterion	Description
Proportionality	Is the policy most efficiently directed at the most important conflicts?
Transparency	Is the policy comprehensible and accessible to the individuals and institutions that may be affected by the policy?
Accountability	Does the policy indicate who is responsible for enforcing and revising it?
Fairness	Does the policy apply equally to all relevant groups within an institution and in different institutions?

Proportionality

First, the criterion of proportionality calls for policies to be efficient and effective in addressing serious conflicts of interest in a preventive or a corrective way. Complicated rules and elaborate procedures can become merely bureaucratic obstacles unless they are implemented and regularly reviewed with the goals of the policy in mind. Do the policies actually address the most important and common conflicts? Are the policies practical; that is, can they actually be effectively implemented at an acceptable cost? Are the policies administered in a way that appropriately considers the likelihood of bias, the seriousness of the harm, and the potential benefits of the conflicting secondary interest (as noted above)? Do the policies and their application unnecessarily interfere with the conduct of legitimate research, teaching, and clinical practice? Do the anticipated benefits of the policies outweigh their various costs, such as administrative burdens, and any negative consequences? The effectiveness of a specific policy can be judged only after that policy has been in use for a period of time. Insofar as experience and evaluations have raised questions about the effectiveness of similar policies already adopted, however, these questions can guide the design and implementation of new policies. Finally, whether policies can achieve their overall aims will also depend on their congruence with other criteria, such as fairness and transparency, that contribute to effectiveness and that are also important for their own sake.

The criterion of proportionality should also be applied in individual situations when an assessment is made of whether a financial relationship constitutes a conflict of interest and, if there is a conflict, how it should be handled. For example, when a researcher's financial relationship with a company is evaluated, its expected benefits as well as its risks should be considered. As discussed in Chapters 1 and 4, industry support for well-designed and scientifically meritorious research tends to advance a primary

goal of generating valid scientific knowledge. This may sometimes mean that an institution should allow an individual with a conflict of interest to participate in an activity because the expected benefits exceed the risks and because the risks have been lowered to an acceptable level. For example, an academic medical center may allow a scientist who holds the patent on a promising discovery to participate in developing a product and designing an early-stage clinical trial to evaluate an intervention because his or her involvement may be necessary to ensure that the product is safely and correctly administered. (These kinds of situations, which should be exceptional, are discussed further in Chapters 4 and 7.)

Transparency

Just as disclosure is usually necessary—even if it is insufficient—in dealing with conflicts of interest, so too is transparency necessary in administering conflict of interest policies. Transparent policies are readily available in clear and simple language, together with explanations and essential information about their application. They are also available not only to those who are subject to them (e.g., researchers, authors of journal articles, or members of practice guidelines panels) but also to other stakeholders, including the public. Transparency is essential to determine whether conflict of interest policies are reasonable and if they are being implemented fairly.

Conflict of interest policies may require the public disclosure of financial and some other relationships under certain circumstances, as described in Chapter 3. These disclosure policies reflect the institutions' ethical and sometimes legal responsibility to disseminate relevant information to appropriate parties. In addition, the values of transparency are also served when institutions explain their judgments in certain cases, for example, when they allow an investigator with a financial stake in the outcome of a study with human participants to conduct that research (see Chapter 4).

Rights of privacy and protection of confidentiality place some limits on how much information an institution discloses and to whom. For example, physicians have a countervailing privacy interest when it is proposed that their financial relationships (and perhaps those of their family members) be disclosed to the public, as noted in the discussion in Appendix F of public disclosure of personal information reported to academic medical centers and other institutions. Disclosures beyond the institution can be limited to the minimum amount of identifiable personal information that is needed to carry out policy goals. For some purposes, reporting aggregate or deidentified information to the public is sufficient.

Transparency can also help improve conflict of interest policies across institutions. Information about the way that one institution has handled a

particular case or type of case can enable other institutions to learn about more and less effective practices and adjust their own policies and behaviors accordingly.

Accountability

Accountable individuals and institutions explain and take responsibility for their conduct and decisions. Thus, just as a physician explains the rationale for clinical decisions to patients and researchers explain the rationale for research and research procedures, so too will leaders of accountable institutions explain their policies and their application to the individuals who are directly affected and respond to questions and suggestions.

Taking responsibility for the consequences of individual or institutional actions and decisions may involve offering apologies or compensation to those harmed by these actions and acknowledging the appropriateness of penalties when a representative of the institution has acted improperly or illegally. To demonstrate that it is accountable, an institution not only will develop explicit conflict of interest policies and procedures for implementing its policies but also will devise ways to communicate how they are applied in practice. Institutional leaders will be prepared to explain how judgments about conflicts of interest are reasonably consistent across similar cases and why, for example, they determined that it was sufficient to require only the disclosure of a relationship in one case but appropriate to manage or prohibit the relationship in another case. Finally, institutional leaders will be ready to respond to questions about their own interests and impartiality. As discussed in Chapter 8, leaders should establish procedures for dealing with the conflicts that their own institutions may have.

Public engagement is often important for accountability. For example, accountability is generally enhanced if public representatives serve on institutional panels that review individual relationships that may present conflicts of interest. To cite a somewhat parallel situation, federal regulations require institutional review boards to include at least one member not affiliated with the institution. Also, as part of a commitment to openness and accountability, organizations may invite public comment on their conflict of interest policies and may take seriously suggestions for revisions. Public participation can enhance the credibility and trustworthiness of decisions about individual cases as well as more general policies.

A final aspect of accountability is a commitment to improving conflict of interest policies and their implementation. Setting benchmarks for performance and tracking outcomes can stimulate quality improvement activities, as has been demonstrated with other activities in health care organizations.

Fairness

The formal principle of fairness requires similar treatment for those in relevantly similar situations and different treatment for those in relevantly different situations. This principle has at least two implications for the application of conflict of interest policies.

First, these policies should apply to all employees or members of an institution who make significant decisions for the institution or who have substantial influence over these decisions. In academic medical centers, these decisions may involve medical education, medical research, or clinical care. Thus, residents, fellows, faculty, members of institutional committees (e.g., institutional review boards, formulary committees, and device purchasing committees), and senior institutional officials are all subject to conflict of interest policies and procedures. Although medical students do not usually have an influence over decisions that are made, they too should be expected to follow conflict of interest rules, which are among the important professional norms they are learning as they prepare for their future careers. At the same time, to be fair, conflict of interest policies and procedures may reasonably differ for people in different roles. For a medical student or resident, the policy issue might be accepting mugs, pens, and lunches from companies. For a senior leader in the institution, the issue might be serving on the board of directors of a company manufacturing medical products and receiving personal compensation for this position. In some cases, the policy response might be to prohibit a practice overall, whereas in other instances management of the conflict could be an option, depending on the specifics of the situation, as assessed by the standards listed in Table 2-1.

Second, fairness requires that individuals in different institutions who are in situations that are similar in all ethically relevant ways be treated similarly. Otherwise, the ethical basis for policies may be called into question and conflict of interest policies and decisions may be regarded as arbitrary. Although conflict of interest regulations for U.S. Public Health Service grantees and policies recommended by the Association of American Medical Colleges allow institutions discretion in setting and implementing policies to take account of local circumstances, it is important to justify such variation in ways that are understandable by and plausible to affected individuals, oversight agencies, and the public.

CONCLUSION

The purposes of conflict of interest policies are expressed in the principles that hold that professionals should act to protect the primary interests of medical practice, education, and research and to maintain public confidence in the integrity of those activities. The problem of conflict of

interest is more complex than is often appreciated. As a result, both critics and defenders of conflict of interest policies sometimes misunderstand or misapply them.

A conflict of interest is not an actual occurrence of bias or a corrupt decision but, rather, a set of circumstances that past experience and other evidence have shown poses a risk that primary interests may be compromised by secondary interests. The existence of a conflict of interest does not imply that any individual is improperly motivated. To avoid these and similar mistakes and to provide guidance for formulating and applying such policies, a framework for analyzing conflicts of interest is desirable.

This chapter has presented principles for assessing conflicts of interest and evaluating policies designed to deal with such conflicts. Conflicts should be assessed by considering various factors that determine their likelihood and seriousness. Likelihood depends on the value of the secondary interest, the scope of the relationship between the professionals and the commercial interests, and the extent of discretion that the professionals have. Seriousness depends on the value of the primary interest, the scope of the consequences that affect it, and the extent of accountability of the professionals. Conflict of interest policies should be evaluated by considering their effectiveness, transparency, accountability, and fairness.

A better understanding of the nature of conflicts of interest and the clearer and fairer formulation of rules can support greater confidence in the medical profession and thereby enable physicians, educators, and investigators to concentrate on their primary missions of treating patients, teaching students, and conducting research. With robust conflict of interest policies in place, they can continue to carry out their respective activities not in wary confrontation but in beneficial cooperation with the representatives of industry.

3

Policies on Conflict of Interest: Overview and Evidence

Current conflict of interest policies and practices have evolved over more than four decades of increasing relationships with industry in medical education, research, and practice. The increase has been accompanied by intensifying discussions about how the risks and the expected benefits of these relationships should be evaluated and balanced. Since 1995, the U.S. Public Health Service (PHS) has required most research grantees to establish policies and procedures to ensure that the design, conduct, or reporting of research funded by PHS grants not be "biased by any conflicting financial interest of an Investigator" (42 CFR 50.601). The regulations, which are included in Appendix B, allow grantees considerable discretion in formulating policies and procedures. To provide more specific and comprehensive guidance to academic institutions on conflict of interest policies, the Association of American Medical Colleges (AAMC, 2001, 2002, 2008c), the Association of American Universities (AAU, 2001), AAMC and AAU jointly (AAMC-AAU, 2008), and the Council on Government Relations (COGR, 2002) have issued several reports with recommendations. The Federation of American Societies for Experimental Biology (FASEB) created a conflict of interest tool kit that offers extensive online resources and guidance for academic institutions, researchers, academic and professional societies, journal editors, and industry (FASEB, 2008). In 2008, the trade associations representing major pharmaceutical and medical device companies revised their codes on company interactions with health care professionals (AdvaMed, 2008; PhRMA, 2008). In addition, a number of academic medical centers, professional societies, medical journals, and other institutions have revised their policies in recent years.

Criticisms of current policies and their application come from different directions. Some object that policies requiring the disclosure of financial

interests can be carried too far, encouraging "readers to make *ad hominem* judgements" (Rothman, 2001, p. 1275) or shifting "attention away from the merits of the work and toward the biography of its author" (Jansen and Sulmasy, 2003, p. 40). Another critic describes disclosure policies as a kind of "new scientific McCarthyism" that assumes that researchers with industry ties are "tainted and untrustworthy" (Whelan, 2008, p. A19). One researcher has criticized "conflict of interest vigilantes" who "search for evidence that doctors have failed to disclose corporate connections in publications or in presentations" (Stossel, 2007, p. 59). He has also argued that continuing medical education disclosure policies mainly serve to protect bureaucrats rather than students, are based on ideology rather than evidence, and "are deeply disrespectful of physicians and researchers" (Stossel, 2008, p. 476). (See Chapter 1 for additional criticisms.)

Others, however, argue that conflict of interest policies—when they exist—are often weak, inconsistent, and inadequately administered and enforced. For example, the American Medical Student Association (AMSA) assessed the conflict of interest policies of medical schools and concluded that the policies of the majority of the schools that responded either lacked important elements or were unlikely to influence behavior (AMSA, 2008b).[1] Whether or not one agrees with how AMSA rated the policies, the actual texts of the policies (available at or through the AMSA website) reveal considerable variability, which is consistent with the findings of this report. Members of the U.S. Congress have strongly criticized physicians and researchers who have failed to report substantial financial relationships with industry, as they were required to do, and have proposed that pharmaceutical and medical device companies be required to report publicly their payments to physicians (see, e.g., Grassley [2008b, 2009]). Also in response to concerns about the nature of financial ties between physicians and industry and the lack of disclosure of such ties, Massachusetts enacted legislation in 2008 that requires companies to report payments to physicians, researchers, and medical societies and further provides for a marketing code of conduct

[1] In AMSA's assessment, 9 medical schools received a rating of A and 19 received a rating of B for their policies; 44 schools received a rating of F (18 for the contents of the policies that they submitted, 9 for their refusal to submit policies, and 17 for their lack of a response after repeated requests). Another 46 schools had policies under revision. (The numbers of schools are based on the ratings listed as of February 13, 2009, at http://www.amsascorecard.org/.) The project's methodology, included the rating system, is available at http://amsascorecard.org/methodology and states that "[e]ach policy was graded by two independent assessors, blinded to the institution of origin. Any differences in scoring between the two assessors were resolved by a consensus process. The assessors received formal training in the use of the scoring system, independently evaluating and coming to a consensus on five training policies before beginning to evaluate the medical school policies."

that will prohibit or limit certain of these payments (Wallack, 2008; Lopes, 2009).

This chapter outlines the basic elements of conflict of interest policies, reviews empirical data about the characteristics and consequences of those policies, and concludes with recommendations. Much of the research and descriptive information located by the committee examined the policies of academic institutions and medical journals; but the recommendations apply broadly to all institutions engaged in medical research, medical education, clinical care, or practice guideline development. The specific elements of the policies may vary according to the size, complexity, and other characteristics of different types of institutions (e.g., academic medical centers, professional societies, patient advocacy groups, and nursing homes).

The focus in this chapter is on policies affecting individuals, primarily physicians and biomedical researchers (as explained in Chapter 1). Chapter 8 examines and makes recommendations about policies that govern institutional conflict of interest, which is defined to include the interests of senior institutional officials.

OVERVIEW OF CONFLICT OF INTEREST POLICIES

Most conflict of interest policies include the basic elements of the disclosure of financial relationships, the prohibition of certain relationships, and the management of conflicts of interest that have been identified. All of these elements are sometimes described under the general rubric of managing conflicts of interest.[2] Other common elements of conflict of interest policies include definitions, specification of who is subject to the policies, enforcement provisions, and identification of which officials or units within an organization are responsible for administering and monitoring conflict of interest policies and procedures. Depending on the circumstances and the type of institution, the person responsible for reviewing initial disclosures may be a department chair, the chair of a professional society committee developing practice guidelines, the editor or deputy editor of a journal, or the chair of a continuing medical education program. When an initial review identifies a possible conflict of interest, the case may be referred to a conflict of interest committee or a more senior official for further evaluation and response.

Building on Chapter 2, Box 3-1 outlines a conceptual model of the

[2] PHS rules refer to procedures to "identify and manage, reduce, or eliminate conflicting interests." Federal government policies for its employees are sometimes described in terms of the "'three-D' method of conflict of interest regulation, that is: disclosure, disqualification and divestiture" (Maskell, 2007, p. 3). Disqualification includes recusal from participation in a specific decision.

BOX 3-1
Model of Steps Used to Identify and Respond to a Conflict of Interest

Step 1 Obtain the disclosure of information about financial and other relationships that could constitute a conflict of interest.

No relationships reported: stop. Relationships disclosed: go to Step 2.

Step 2 Evaluate the disclosures—in light of the individual's responsibilities or specific activities (e.g., research, teaching, and patient care)—to determine whether a conflict of interest exists. If necessary, collect additional information to assess the likelihood of undue influence and the seriousness of possible harms.

No conflict exists: stop. Conflict exists: go to Step 3.

Step 3 Determine whether the relationship is one prohibited under institutional or other policies or whether the risks of the relationship are so serious that the individual should either eliminate it or forgo participation in the activity put at risk by the relationship.

Conflict elimination necessary: go to Step 5.
Elimination not necessary: go to Step 4.

Step 4 If management is appropriate, devise and implement a plan to manage the conflict. Go to Step 5.

Step 5 Monitor conflict elimination or management plan and assess adherence.

Plan followed. Plan not followed: go to Step 6.

Step 6 Determine the nature of the noncompliance and the appropriate response (e.g., education, penalty, or revision of the plan) and implement the response.

steps that institutions with a comprehensive conflict of interest policy and implementation strategy might follow when determining whether an individual has a conflict of interest and, if so, how to respond. It shows the elimination of an identified conflict of interest as an early step, although the committee's experience suggests that the elimination of a conflicting relationship is often considered a last option.

A given individual may be covered by several conflict of interest policies. For example, a medical school faculty member may have to understand and follow the policies not only of the medical school but also those of

several other institutions. Depending on his or her activities, these other policies might include those of a medical journal, a provider of continuing medical education, a professional society, or a federal advisory committee. If a faculty member is engaged in research to support an application for marketing approval of a medical product by the Food and Drug Administration (FDA), the researcher can expect the study's sponsor to ask for the disclosure of his or her financial interests related to the company and the investigational product so that the sponsor can submit the required information to the FDA (FDA, 2001). (A recent report by the Office of the Inspector General [OIG] of the U.S. Department of Health and Human Services criticized the administration of these policies and indicated that they were deficient in several respects [OIG, 2009].) Private organizations that fund research, such as the Howard Hughes Medical Institute, also may have conflict of interest policies, which they may oversee directly rather than following the practice of the National Institutes of Health (NIH) of delegating most administrative responsibility to the research institution (Cech and Leonard, 2001). In addition, the faculty of public institutions will likely be covered by state conflict of interest policies.[3]

The committee found few reviews or studies documenting and comparing the conflict of interest policies of institutions engaged in medical research, medical education, or clinical care. It found even less information about the implementation and effects of these policies. Most studies examine the policies of academic institutions, medical and scientific journals, or government agencies. Journal articles or news stories sometime report on individual professional societies and patient or consumer groups.

In addition, through its literature review, public meetings, and other information-collecting activities, the committee identified various examples of institutional policies.[4] Although these examples are not necessarily representative, they helped the committee better understand the nature of policy variability and, in some cases, the rationale for policy differences. Institutions differ considerably in the conflict of interest policy information that they make public on their websites; and even if they are available, online information is not necessarily comprehensive, clear, or current. Since the committee began work, a number of medical schools, professional societies, and other groups have announced changes in their conflict of interest

[3] The state of Washington recently changed its policies on the use of certain university resources for outside work for faculty and some other university employees to "encourage the ethical transfer of technology for the economic benefit" of the state (University of Washington, 2008).

[4] During the study, the committee benefited from initiatives by AMSA and the Institute on Medicine as a Profession to make medical center policies available online. These databases have been useful, although they are not complete, and many schools have indicated that they are updating their policies.

policies and practices. Thus, even relatively recent overviews of conflict of interest policies may be somewhat out of date.

DISCLOSURE: AN ESSENTIAL BUT INSUFFICIENT ELEMENT OF POLICY

Disclosure—that is, revealing to others information that may otherwise be private or confidential—is a frequent response to concerns about conflicts of interest in various sectors of society. Disclosure by physicians and researchers to their academic or other institution is essential because institutional officials cannot evaluate and respond to individuals' relationships with industry if they are not aware of them. Consistent with the conceptual framework outlined in Chapter 2, disclosures should provide sufficient information about the nature, scope, duration, and monetary value of relationships to allow institutions to assess the risk that secondary interests might unduly influence judgments about research, clinical care, education, or other primary interests.

The committee distinguished disclosure to the physician's or researcher's institution from disclosure beyond the institution, for example, to patients, research participants, or the public.[5] One rationale for disclosure—especially public disclosure—is the deterrence of questionable or inappropriate relationships. As Supreme Court Justice Louis Brandeis (1914) famously expressed it, "sunshine is said to be the best of disinfectants." In a similar vein, the code of ethics of the American College of Physicians suggests that physicians considering the acceptance of gifts or other relationships with companies should ask themselves what their patients, the public, or their colleagues would think about the arrangement (Snyder and Leffler, 2005; see also Chapter 6). The *Nature* publishing group urges authors to avoid "any undeclared competing financial interests that could embarrass you were they to become publicly known after your work was published" (NPG, 2008).

Disclosure should have beneficial consequences if it leads physicians to avoid gifts, the use of industry-controlled presentations, and other relationships that create a risk of compromising their decisions and their professional independence. It could also have harmful consequences if physicians or researchers react by avoiding relationships that promote im-

[5] Some analyses refer to the provision of information to institutional officials as "reporting" and reserve the term "disclosure" for the revelation of information to members of the public (e.g., journal readers or patients) (see, e.g., AAMC [2001]). In contrast, some policies refer to reporting of information to external groups. This report follows the common usage (including in federal policies and guidance) and applies the term "disclosure" to the provision of information to internal parties as well as to external parties.

portant societal goals and that are accompanied by adequate measures to protect objective judgment.

What Is Known About Disclosure Policies, Practices, and Consequences

This section first reviews information about the characteristics of disclosure policies and practices. It then turns to evidence about the effectiveness of disclosure.

Presence and Scope of Disclosure Requirements

Medical schools The most recent comprehensive study of medical school conflict of interest policies reports on a 2003 AAMC survey of member schools (response rate of 82 percent) that was designed to characterize their policies and assess the extent to which they were consistent with the association's 2001 recommendations on conflict of interest in clinical research (Ehringhaus and Korn, 2004).[6] It found considerable variation. Almost all (95 percent) of the respondents reported that their policies covered all research involving human participants regardless of the funding source.[7] Sixty-eight percent of the schools used the PHS threshold ($10,000)[8] for individuals to disclose certain financial interests to the institution, whereas 27 percent reported a lower threshold. For elements not required by the PHS regulations, more than 60 percent of the respondents requested disclosure to the institution of equity in nonpublicly traded companies, regardless of the percent share (61 percent) or the estimated valuation (64 percent). The majority requested the disclosure of royalty income either above a certain threshold (38 percent) or regardless of the amount (33 percent).

In addition to requiring disclosure to the institution, policies may also require that financial relationships or conflicts of interest be disclosed to individuals who might be affected by the relationship. These might include research colleagues, research participants, journal readers, students, or

[6] The committee also reviewed several earlier studies for additional context and understanding of policy evolution (see, e.g., Cho et al. [2000], Lo et al. [2000], and McCrary et al. [2000]).

[7] In 2004, the Government Accountability Office reported that 79 percent of universities responding to their survey said that they had a single conflict of interest policy that covered all research. This is consistent with the recommendation of the AAU Task Force on Research Accountability that "all research projects at an institution, whether federally funded, funded by a non-federal entity, or funded by the institution itself, should be managed by the same conflict of interest process and treated the same" (AAU, 2001, p. 5).

[8] The PHS regulations state that individuals do not need to report "salary, royalties or other payments that *when aggregated for the Investigator and the Investigator's spouse and dependent children* over the next twelve months, are not expected to exceed $10,000" (NIH, 2008a, question C6, emphasis added). A similar rule applies to the disclosure of equity interests.

TABLE 3-1 Percentage of Medical Schools Requiring Further Disclosures for Researchers with a Significant Financial Interest in Their Research

Further Disclosure Required	Percentage of Medical Schools
To research participant in informed consent forms	74
To sponsors or funders of the research	65
To editors of journals to which papers or reports of research are submitted	64
In oral presentations of research results	60
In multicenter trials, to investigators, sponsors, and other institutional review boards participating in the trial	42
Other	23

patients. Again, the AAMC survey showed variation in medical school policies (Table 3-1).

A study by Weinfurt and colleagues (2006b) also reported on variations in disclosure policies. Forty-eight percent of medical schools had policies that mentioned the disclosure of researchers' financial conflicts of interest to research participants. The policies varied in what information was to be disclosed.

Medical and scientific journals The International Committee of Medical Journal Editors (ICMJE) has proposed Uniform Requirements for Manuscripts Submitted to Biomedical Journals that include explanations and provisions about conflicts of interest (ICMJE, 2008). The ICMJE website lists several hundred journals that follow these requirements, but the group does not verify the extent to which a journal does so. The World Association of Medical Journal Editors (WAME) has also made recommendations on conflict of interest policies (WAME, 2008).

Even journals that adopt conflict of interest policies may not apply them equally to industry-funded journal supplements that present papers from a conference or collections of papers on a particular topic. These supplements are generally not peer reviewed and have been criticized for including articles of lower quality (Bero et al., 1992; Rochon et al., 1994). The National Library of Medicine will not cite and index articles from certain types of sponsored supplements unless they include specific disclosures about "any financial relationship the guest editors and authors have with the sponsoring organization and any interests that organization represents, as well as with any for-profit product discussed or implied in the supplement and/or individual articles" (NLM, 2007, unpaged).

Journals may also vary their policies for review articles and editorials

or may not apply their policies to review articles and editorials, which arguably offer more room for bias than original research articles. For example, a 2004 editorial in the *Journal of the American College of Cardiology* stated that the editors generally decline publication of review articles disclosing industry input out of concern for external influence and subtle bias (DeMaria, 2004). Editors of another journal initially declared that they would not accept review articles written by authors with conflicts of interest and then decided that it would accept such articles if the conflicts were not significant (e.g., they involved payments that were less than $10,000) (Drazen and Curfman, 2002).

Two recent analyses found considerable variability in the conflict of interest policies of medical and scientific journals. Cooper and colleagues (2006b) found that 93 percent of biomedical journals reported that they had conflict of interest policies applicable to authors, 46 percent reported that they had policies applicable to reviewers, and 40 percent reported that they had policies applicable to editors. Fifty-seven percent reported that they published disclosures for all articles. Earlier studies reported that the percentage of biomedical journals with disclosure policies was lower (see, e.g., McCrary et al. [2000] and Krimsky and Rothenberg [2001]). Ancker and Flanagin (2007) were able to locate online conflict of interest policies for only 33 percent of 84 "high-impact, peer-reviewed" journals in 12 scientific disciplines, but a subsequent survey found that 80 percent of the 49 responding journals reported that they had policies in place.

Journals vary in whether they give specific guidance to authors regarding what financial relationships or conflicts of interest must be disclosed. Ancker and Flanagin (2007) found that 68 percent of journals provided examples of conflicts of interest and 46 percent defined the term. The committee's review of a convenience sample of journal policies revealed differences in the specificities of the policies. One journal advises simply, "[a]uthors are required to disclose any sponsorship or funding arrangements relating to their research and all authors should disclose any possible conflicts of interest" (AJN, 2008). In contrast, the *New England Journal of Medicine* states that disclosures are to include "all of the authors' relationships with companies that make products studied or discussed in the article, companies that make related products, and other pertinent entities with an interest in the topic" (NEJM, 2008). Some journals ask authors about several specific types of relationships and also ask them to indicate explicitly if they have no relationships. One journal's manuscript agreement form asks authors to certify that their manuscript has not been sponsored by a commercial entity and that if their manuscript includes no acknowledgments, it means that nonauthors have made no substantial contribution to it (AFMI, 2008).

Professional societies and patient advocacy groups The committee found no published reviews of the disclosure policies of professional societies. It examined a convenience sample of professional society documents and websites and found considerable variation in the content and accessibility of those policies. (Unlike professional society codes of ethics or codes of conduct, disclosure policies do not apply to members generally but are limited to individuals holding positions of responsibility, for example, officers or members of policy-making committees.) Some societies had disclosure forms with a simple, open-ended question about relevant relationships, whereas other forms included specific categories of relationships and required that respondents either report such a relationship or check a box stating that they had none. The policies of some professional societies that develop clinical practice guidelines are discussed further in Chapter 7.

The committee did not attempt to conduct a systematic review of the policies of patient advocacy and disease-specific groups. It found little information on such policies in its initial search of organizational websites and other resources. To the extent that these groups engage in activities such as the development of clinical practice guidelines or the provision of accredited continuing medical education, many of the recommendations in Chapter 7, in this chapter, and elsewhere in this report will apply.

Disclosure by Companies of Payments to Physicians

District of Columbia, Maine, Massachusetts, Minnesota, Vermont, and West Virginia require pharmaceutical manufacturers to report their financial relationships with physicians; and a number of other states are considering such requirements (Wallack, 2008; Lopes, 2009; MedPAC, 2009). Minnesota and Massachusetts make the information public. Vermont requires the state's attorney general to make an annual public report based on the information that the pharmaceutical manufacturers have disclosed. Two states also require the reporting of payments by pharmaceutical manufacturers to hospitals and nursing homes. One state requires medical device companies as well as pharmaceutical companies to report payments to physicians. In general, state policies are relatively new, and their implementation and effectiveness have not been formally assessed.

Some pharmaceutical and device companies have voluntarily acted to disclose publicly certain of their payments to physicians (see Chapter 6). The specific details of company plans vary and appear to be evolving as the discussion of public reporting of payments continues. Several companies have been required to make such public disclosures as a condition of settlements with the U.S. Department of Justice (Demske, 2008; see Chapter 6 for additional discussion). In 2007, bills were introduced in the U.S. Congress to establish a requirement for companies to report publicly

their payments to physicians (S. 2029 and H.R. 5605, 110th Congress). As discussed in the final section of this chapter, the Medicare Payment Advisory Commission (MedPAC), which advises the Congress on a range of Medicare policy issues, has recommended a more comprehensive policy for company reporting of payments (MedPAC, 2009).

Time Frame for Disclosure

For employees and others who are involved with an institution for an extended period, disclosure policies generally require an initial disclosure and then periodic (e.g., yearly) disclosures as well as interim disclosures when new relationships arise or when specific events occur (e.g., the submission of a new grant proposal or an application to license intellectual property). For researchers, policies may require the disclosure of financial ties before a study begins (e.g., to university administrators and institutional review board members), during a study, (e.g., to the research team, students, or research subjects), and after the study is completed (e.g., to journal editors when papers are submitted for publication in peer-reviewed journals).

The conflict of interest policies that the committee reviewed varied considerably in the time periods for which disclosure is required. Typically, policies require the disclosure of relationships that are current or that occurred during the previous year. Some policies ask about relationships that are pending, in negotiation, or expected in the next 12 months. The PHS regulations for grantees do not specify a reporting period, except that in determining whether financial relationships exceed the $10,000 threshold for reporting, researchers must consider individual and family financial relationships projected for the next 12 months.

Some organizations require disclosure for periods longer than the previous year (e.g., the American Thoracic Society requires disclosure for the previous 3 years [ATS, 2008] and the *Journal of the American Medical Association* requires disclosure for the previous 5 years [Flanagin et al., 2006]). The requirements may vary by type of relationship. For example, the policy of the American Society of Clinical Oncology specifies disclosure within 2 years for certain relationships (e.g., honoraria and consulting arrangements) but not for others (e.g., research funding) (ASCO, 2007).

Administrative Burden of Disclosure Policies

Disclosure to multiple organizations with various policies can clearly be burdensome for individuals who have received multiple grants, write many papers, serve on various committees and advisory panels, and make many continuing medical education presentations. The committee found little em-

pirical information on the administrative burden of disclosure or other elements of conflict of interest policies for either individuals or institutions.

A 2007 faculty burden survey undertaken for the Federal Demonstration Partnership reported that respondents assigned conflict of interest monitoring an average burden rating of about 1.8 (with a rating of 1 being no burden and 5 indicating a great deal of burden), whereas grants progress reporting received a rating of 3.4 (with a rating of 3 being some burden) (Decker et al., 2007).[9] Some other government-led initiatives to streamline regulatory policies and practices mention conflict of interest policies and practices but generally do not identify them as a critical issue or problem.[10]

The committee found examples of efforts to make it easier for individuals to comply with disclosure policies. For example, to assist their employees in determining whether they have a relationship with a "substantially affected organization" (as described in NIH intramural conflict of interest policies), NIH has developed a searchable list of such organizations (http://ethics.od.nih.gov/topics/sao/sao-list.aspx). Similarly, to help committee members identify and report pertinent relationships, some federal advisory committees and at least one professional society (the American Society of Clinical Oncology) have developed lists of for-profit companies that make products that might be affected by committee decisions on a particular issue (ASCO, 2008).

[9] The response rate for the survey, which was directed to faculty at major research institutions, was less than 40 percent. The Federal Demonstration Partnership, which involves 10 federal agencies and approximately 100 institutional recipients of federal funds, is a cooperative initiative whose goal is to reduce the administrative burdens associated with research grants and contracts (http://thefdp.org/). An earlier partnership survey found that conflict of interest monitoring was cited among the tasks for which respondents received the least institutional assistance (Wimsatt et al., 2005).

[10] For example, the Research Business Models subcommittee, which is under the Committee on Science of the National Science and Technology Council, has, among other priorities, the development of "specific guidance or regulations concerning institutional financial conflicts of interest, and to resolve differences in conflict of interest interpretations and terms and conditions of Federal grant awards" (http://rbm.nih.gov/priorities/sa3.htm). At NIH, the Clinical and Translational Science Awards (CTSA) program has established a research ethics oversight committee, which has in turn created a work group on conflict of interest policies to survey CTSA sites and gather information on policies. The NIH initiative to "reengineer the clinical research enterprise" does not feature conflict of interest policies as part of its assessment of clinical research policies (http://nihroadmap.nih.gov/clinicalresearch/overview-policy.asp). Nonetheless, the presentation to the IOM committee by NIH Director Elias Zerhouni stated that improving conflict of interest administration for grantees was important to NIH (Zerhouni, 2007).

Accuracy and Completeness of Disclosures

Although most organizations are reluctant to publicize violations of their policies, instances of incomplete and inaccurate disclosure periodically make news. For example, in 2008, investigations by U.S. Senate Finance Committee staff led to a front-page story in the *New York Times* on the failure of three Harvard faculty members to disclose in full—even after they were asked to file amended disclosure forms—the substantial payments that they had received from pharmaceutical companies over the period from 2000 to 2007 (Harris and Carey, 2008; see also Grassley, 2008b). (The Senate committee staff obtained the data through separate inquiries to companies and medical schools and then compared the responses.) In some cases, it appeared that the disclosures that had been omitted involved companies whose products the researchers were investigating. The present Institute of Medicine (IOM) committee understands that one of the questions about these cases is whether the institution's disclosure policy actually requested all the information specified in the PHS regulations, but further details of investigations into the matter had not been released as this report was being completed.

Although the IOM committee did not examine the issue, it notes that journalists often fail to report the sources of funding for research that they publicize (see, e.g., Cook et al. [2007]). In addition, journalists themselves may report stories involving pharmaceutical, medical device, or biotechnology companies with which they have conflicts of interest, for example, the acceptance of company-sponsored travel or prizes for reporting or the reliance on opinion leaders suggested and paid by companies (see, e.g., Schwartz et al. [2008]).

Newspapers have also publicized examples of failures by NIH intramural scientists to disclose relationships with industry as required by agency rules and examples of scientists who have maintained relationships that would likely not have been approved under the rules. For example, journalists reported the apparent failure of dozens of NIH scientists to disclose relationships with industry, although only 20 or so actual cases were confirmed in a subsequent investigation performed by NIH (see, e.g., Weiss [2005]). Another story reported on a researcher who was found by an internal investigation to have "actively" chosen in "at least 38 separate instances . . . not to adhere to policies because it was inconvenient or time-consuming; he knew it was likely his participation [with the pharmaceutical companies] would have been disapproved" (Willman, 2006). A report from the OIG of the U.S. Department of Health and Human Services criticized the agency for not obtaining adequate documentation for the outside financial relationships that it explicitly approved (OIG, 2005).

Although cases of nondisclosure may receive considerable publicity,

the frequency and extent of deliberate or unintentional underreporting is unknown, and alternative methods for improving the accuracy of disclosure have not been tested.[11] Weinfurt and colleagues (2008c) reported incomplete and inconsistent disclosure in articles on coronary stents published in 2006. They found that 75 authors disclosed at least one relationship with a pharmaceutical company or other organization, but for only 2 of those authors was that relationship disclosed in all of the authors' articles. Weinfurt and colleagues did not, however, take into account whether some journals either did not require certain relationships to be disclosed or chose not to publish the disclosures with an article. If a national system of public disclosure of payments by pharmaceutical, medical device, and biotechnology companies is enacted, institutions could verify the disclosures that they receive.

Monitoring and Enforcement

The committee found no peer-reviewed studies on the monitoring or enforcement of disclosure requirements specifically or conflict of interest policies generally. One study of journal policies reported that of the 28 journals that had a disclosure policy for authors, 13 had policies that were silent on procedures for responding to an author's failure to make a disclosure (Ancker and Flanagin, 2007). As a means of informing readers and also of promoting adherence to their policies, journals from time to time report on cases in which authors did not disclose pertinent relationships with industry (see, e.g., Petersen [2003], Armstrong [2006], Chabner [2008], DeAngelis and Fontanarosa [2008], and Ross et al. [2008]). They sometimes require these authors to write a letter to the editor acknowledging the error (see, e.g., Kurth et al. [2006], Matteson and Bongartz [2006], and Henschke and Yankelevitz [2008]).

A few journals have more stringent penalties. For example, after problems with authors' failures to disclose, the journal *Environmental Health Perspectives* adopted a policy that (1) imposes a 3-year ban on the publication of articles by authors who have "willfully failed to disclose a competing financial interest" and (2) provides for the publication of a retraction if the editors conclude that they would have rejected the article initially had they known of the undisclosed relationships (EHP, 2009). In general, however, journals decline "to become the COI [conflict of interest] investigative

[11] Although the committee did not locate assessments of different disclosure forms, two studies have assessed procedures for obtaining information about the contributions of the listed authors to a submitted manuscript (e.g., analysis of data and drafting of the manuscript) (Marusič et al., 2006; Ivanis et al., 2008). One found that open-ended forms yielded significantly less information than forms with explicit response categories (Marusič et al., 2006). Those studies were also replicated using different disclosure formats.

squad" and "count on . . . authors to be forthright with us" (Goldsmith, 2006, p. 2148). In addition to exposing offenders to negative publicity, journal reports about failures to make the necessary disclosures may have other consequences for authors. In one case, the Mayo Clinic required investigators found to have made incomplete disclosures to a journal to undergo an internal investigation and to participate in remedial activities (Matteson and Bongartz, 2006).

AAMC has recommended that academic medical centers specify the possible sanctions for noncompliance with policies governing conflicts of interest in research involving human subjects and then regularly assess compliance (e.g., through internal audit mechanisms and other self-evaluation strategies) (AAMC, 2001). A 2003 AAMC survey, which did not review actual policies but which relied on responses to survey questions, found that 80 percent of respondents reported that their policies had sanctions for violations (Ehringhaus and Korn, 2004).

The AMSA assessment cited earlier suggests variability in the oversight and enforcement of conflict of interest policies. On the basis of a review of medical school policies, the report categorized institutions as either having or not having provisions for oversight and enforcement (AMSA, 2008b).[12] Of the 58 schools that initially responded to the survey and supplied written policies for review, 55 percent were characterized as having oversight policies, 45 percent were characterized as having enforcement policies, and 34 percent were characterized as having both.[13]

A report by the Council on Government Relations (COGR; an association of research universities) also suggested inadequacies in the procedures used to promote compliance with conflict of interest policies. It concluded:

> While virtually all research universities and organizations have written policies governing individual financial conflicts of interest in research-related areas, most institutions are still developing formal and informal education programs to assure that the policies are well understood and that compliance by affected faculty and researchers is fully in place. (COGR, 2002, unpaged)

[12] As described in footnote 1, two independent, trained reviewers read the policies that the medical schools submitted (without identifying information) and then rated them according to specified criteria. For the administration and oversight categories, the reviewers gave yes or no answers to these two questions: Is it clear that there is a party responsible for general oversight to ensure compliance? Is it clear that there are sanctions for noncompliance?

[13] Some schools that at first failed to provide relevant policies have since supplied or indicated that they will supply additional information (personal communication, Gabriel Silverman, AMSA Scorecard Director, AMSA, June 6, 2008).

Effectiveness of Disclosure Policies

A physician's or researcher's disclosure of financial relationships, either to the institution or to a broad audience, is a necessary step for identifying and avoiding or managing conflicts of interest, but it also has important limitations. First, disclosure alone does not resolve conflicts of interests or prevent the harms that may result from a conflict. Second, some evidence suggests that the disclosure of a conflict of interest may have little effect or may even be counterproductive in some circumstances.

Experimental studies in psychology Several experimental studies in psychology raise general questions about the effectiveness of disclosure of a conflict of interest and even suggest the potential for unintended adverse consequences. For example, in two sets of experimental studies of disclosure by individuals in an advice-giving role, researchers concluded that the disclosure of conflicts of interest significantly benefited the advice givers but hurt the interests of those to whom the disclosure was made (Cain et al., 2005). Although the authors of those studies noted that the findings should be treated as no more than evidence that disclosure can potentially have unintended consequences, they caution that most of the mechanisms that produce the effects found are likely to exist except when the recipients of the advice are savvy and experienced.

The disclosure of financial relationships can also be ineffective for reasons unrelated to those discussed in the studies just cited. For example, when a large amount of information is disclosed (e.g., on prescription inserts or in certain informed-consent forms), critical points can get lost among less important details. That is, the disclosure of more information may, in some situations, be counterproductive. (Appendix D provides an additional review of the relevant psychological research.)

Journal readers Two randomized studies suggested that the disclosure of an author's financial interests can reduce journal readers' perceptions of the believability and importance of research reports. One study found that journal readers found an article to be less "interesting, important, relevant, valid, and believable" when the authors were disclosed to be employees of a (fictitious) pharmaceutical company instead of employees of an ambulatory care center (Chaudhry et al., 2002, p. 1392). The other study found that readers rated "importance, relevance, validity, and believability" lower if it was disclosed that the authors had stock holdings rather than nothing to disclose and if it was disclosed that the authors had received a research grant from a company rather than nothing to disclose (Schroter et al., 2004).

Research participants Several studies have suggested that disclosures to prospective research participants of investigators' financial relationships have little impact on decisions to participate in research (see, e.g., Kim et al. [2004], Hampson et al. [2006], Weinfurt et al. [2006a, 2008a,b]), and Gray et al. [2007]. In a survey of participants in clinical trials for the treatment of cancer, more than 70 percent of the respondents would still have enrolled in the clinical trial even if the researcher had financial ties to the pharmaceutical company sponsoring the trial or had received royalty payments (Hampson et al., 2006). Only 31 percent wanted the researcher's financial interests to be disclosed.

Other studies have described hypothetical clinical trials to individuals with chronic diseases and varied the kind of information presented about the researchers' financial relationships with the sponsors of the trial (Weinfurt et al., 2008a,b). The respondents' willingness to participate in a hypothetical clinical trial varied substantially, depending on the type of financial relationships. The respondents were more concerned when the researchers held equity in the sponsoring company than when the researchers received a payment to cover the cost for each participant in the study. Trust in the researchers decreased somewhat after the disclosure of equity interests. Other factors, such as the benefits and the risks of the clinical trial, had more of an impact on the respondents' decision to participate in the trial.

These studies of research participation can be criticized on methodological grounds for not explaining the risks of conflicts of interest (e.g., bias in the conduct of research and the failure to publish negative findings) or not linking the responses to actual decisions about research participation. It is not known whether the respondents might have been more concerned about researchers' financial relationships with sponsors if they had been given background information about the risks.

Patients Several surveys in the 1990s suggested that many patients were not aware of industry gifts to physicians but were relatively tolerant of most gifts. One study suggested that, overall, patients were considerably more likely than physicians to believe that gifts from pharmaceutical companies influenced physician practice, but only 54 percent of patients were aware of such gifts (Gibbons et al., 1998; see also Blake and Early [1995] and Mainous et al. [1995]). On a different but related issue, one study of the disclosure of information about physician payment mechanisms in managed care plans found that disclosure did not reduce patients' trust in their physicians and might even have "a mild positive impact" on trust (Hall et al., 2002, p. 197; see also Pearson et al. [2006]). Other studies have suggested that patients are interested in information about how their physicians were paid or, more generally, what financial incentives the patients'

health plan imposes on participating physicians (Kao et al., 2001; Levinson et al., 2005). (Chapter 6 briefly discusses conflicts of interests created by physician payment methods.)

PROHIBITING OR ELIMINATING CONFLICTS OF INTEREST

Prohibition as a Preventive Strategy

Some institutions have conflict of interest policies that prohibit certain financial relationships outright because their risks are considered to greatly outweigh any potential benefits. As described further in Chapter 5, a 2008 report by AAMC recommended that academic medical centers prohibit a wide range of financial relationships with industry. Several medical schools (e.g., the University of Pittsburgh, the University of Texas Medical Branch at Galveston, and the University of California system) have policies prohibiting gifts, and some prohibit participation in company speakers bureaus (e.g., the University of Massachusetts, the Mayo Clinic, and the University of Louisville).[14]

Also in 2008, the Pharmaceutical Research and Manufacturers of America revised its *Code on Interactions with Healthcare Professionals* to state that companies should not offer pens, notepads, and other non-educational items to health care professionals. In Massachusetts, recent legislation gives these guidelines legal force by requiring the public health department to establish "regulations for a marketing code of conduct . . . that shall be no less restrictive than the most recent version" of the codes on interactions with health care providers of the Pharmaceutical Research and Manufacturers of America and the Advanced Medical Technology Association (see Chapter 111N, section 2, Massachusetts Senate No. 2863). Thus, policies may forbid both the giving and the receiving of certain gifts. (Implementing regulations were published in March 2009 [see Lopes, 2009; see also Chapter 6].)

Some conflict of interest policies prohibit certain relationships but allow exceptions. For example, federal policies covering NIH and other employees of the U.S. Department of Health and Human Services state that its employees may not have an "employment relationship" with drug, medical device, or biotechnology companies; grantees; health care providers; or health insurers. They also may not be paid to teach, speak, write, or edit for such organizations. The policies allow for prior approval of certain

[14] Except for the information for the University of California system (University of California, 2008), this information comes from policies summarized by AMSA (2008b) and then checked by reference to documents on the AMSA website or through links to those documents.

exceptions if prohibition of a relationship is not "necessary to ensure public confidence in the impartiality or objectivity with which HHS programs are administered" (HHS, 2005, p. 51572).

To cite another example, AAMC recommends that medical schools set a "rebuttable presumption that an individual who holds a significant financial interest in research involving human subjects may not conduct such research . . . [except when] the circumstances are compelling" (AAMC, 2001, p. 7). (The "rebuttable presumption" concept is taken from the law and refers to assumptions that are taken to be true unless they are explicitly and successfully challenged in a particular case.) A compelling circumstance would exist, for example, if a researcher with a conflict of interest has unique expertise or skill with implanting and adjusting a complex new medical device and this expertise is needed to carry out an early-stage clinical trial safely and competently. Generally, some kind of management plan would then be devised. This approach is discussed further in Chapter 4.

Prohibition or Elimination as a Management Strategy

The options for managing conflicts of interest discussed in the next section all permit the continuation of a relationship in some situations in which a conflict exists. In certain cases, however, continuation of the relationship is not acceptable because of the severity of the threat that it poses to the primary interest. In that case, an individual with a conflict of interest may agree to end the relationship that creates the conflict, for example, by selling company stock, resigning from a company governing or advisory board, or ceasing to consult for a company. Alternatively, an individual with a conflict of interest may decide to forgo participation in such an activity rather than eliminate the financial relationship in question. Some relationships with conflicts of interest may be difficult to eliminate, for example, the relationship with a spouse because of a conflict of interest involving the spouse's employment.

The committee found no systematic assessment of the adoption, implementation, or effectiveness of policies prohibiting certain financial relationships with industry. Somewhat more information is available on the management of conflicts of interest.

EVALUATING AND MANAGING CONFLICTS OF INTEREST

The management of a conflict of interest is necessary when an assessment of an individual's financial relationships identifies a conflict of interest and when disclosure alone is inadequate but elimination of the conflict is a requirement that is too severe. AAMC has recommended that medical schools create conflict of interest committees to make these assessments and

propose management strategies, when appropriate. Professional societies may rely on senior staff or members (e.g., chairs of guideline development panels) for assessments of relationships and responses.

The management options will vary depending on the nature of the conflict and the activity under consideration. Examples of management options follow:

- asking an individual with a conflict of interest to reduce the value of a financial relationship so that it falls below a threshold amount;
- requiring that an individual forgo participation in committee votes, deliberations, or decisions about a topic related to that individual's conflict of interest;
- modifying the design of a research project or having a researcher with no conflict of interest serve as the principal investigator; or
- providing an observer to monitor and evaluate the content of a continuing education course conducted by an individual with a conflict of interest for bias.

What Is Known About Management Policies, Practices, and Consequences

The available data suggest that institutions vary considerably in how they oversee and manage conflicts of interest. Ehringhaus and Korn (2004) reported that 76 percent of medical schools responding to the 2003 AAMC survey had established, as recommended by AAMC, a standing committee to evaluate conflict of interest disclosures, and 21 percent included at least one committee member from outside the institution, also as recommended by AAMC. Eighty-one percent of the medical schools responding to the AAMC survey allowed investigators with a significant financial interest to conduct research involving human participants when compelling circumstances exist. Only 61 percent of the respondents indicated that they had adopted the rebuttable presumption or a similar strategy, and only 26 percent indicated that they had a definition of the compelling circumstances or similar conditions that would allow rebuttal of the presumption.

Even within a single university system, conflict of interest practices may vary (see, e.g., several studies of the University of California system reported by Boyd et al. [2004], Lipton et al. [2004], and Boyd and Bero [2007]). For example, within the University of California system, some campuses have standing committees that meet at least monthly, whereas others convene committees on an ad hoc basis (Boyd et al., 2004). Some but not all campuses include committee members from outside the campus community. Some committees are structurally linked through centralized computer systems to other oversight bodies, such as the campus institu-

tional review board, whereas others do not share financial information within the university unless they are asked to do so.

Assessing Risks of Disclosed Relationships

If an organization's policy requires more than just disclosure, the next step is a review to assess whether a disclosed relationship constitutes a conflict of interest and what risks or potential benefits the relationship presents. As described earlier, a department chair or similar individual may review disclosures and identify conflicts of interest or may refer potential conflicts of interest for further review by a conflict of interest committee or other group or official.

The IOM committee found little systematic investigation of the institutional practices and or criteria used to assess financial relationships and conflicts of interest. One small qualitative study of a university system found that individual conflict of interest committees made decisions on a case-by-case basis, taking into account multiple considerations (e.g., the extent and the nature of the financial relationship and the type of research and research design) and following no rigid formula (Boyd and Bero, 2007). The committees rarely made a direct assessment of the likelihood that an investigator would act improperly.

Some specific advice on assessing the severity of conflicts of interest is available. The AAMC-AAU report on conflict of interest in research involving human subjects describes several considerations that should be taken into account when the risks and possible benefits of allowing an investigator with a conflict of interest to participate in such research are assessed (AAMC-AAU, 2008) (Box 3-2).[15] It also discussed the application of these questions to 10 illustrative cases.[16]

The FDA has developed guidance on whether an individual with a conflict of interest should be allowed to serve on one of its advisory committees (FDA, 2008b). Some of the questions roughly correspond to the considerations identified in Chapter 2. For example, one question is whether a "particular matter" under consideration by a committee

> will have a direct and predictable effect on the financial interests of any organization? . . . A "predictable" effect . . . is a real, as opposed to a

[15] In general, this report follows the practice of recent IOM reports in referring to research participants rather than research subjects (see, e.g., IOM [2001, 2003, 2004]; see also NBAC [2001]). When quoting and sometimes when referring to AAMC and other reports that employ the latter usage, the report follows their practice.

[16] The 2002 report by COGR also included an analysis of cases, and some university educational materials likewise feature analyses of case studies as a means of providing an understanding of the risks presented by financial relationships (see, e.g., Columbia University [undated]).

BOX 3-2
Risks and Potential Benefits to Consider in Assessing the Severity of a Researcher's Conflict of Interest

- Risks to human subjects: to what extent could the conflict of interest increase the risk (considering the role specified for the researcher with the conflict of interest in recruiting or treating research participants)?
- Risks of bias in data collection, analysis, and reporting: to what extent could the researcher with the conflict of interest compromise the integrity of the data?
- Risks to reputation: to what extent could the reputation of the researcher with the conflict of interest or the researcher's institution be damaged, even if the institution establishes a plan to manage the conflict?
- Expected benefits to medicine, science, and public health: how do the expected benefits of allowing the research to proceed compare with the risks?

SOURCE: Adapted from AAMC-AAU, 2008.

> speculative, possibility that the matter will affect the financial interest. It is not necessary, however, that the magnitude of the gain or loss be known, and the dollar amount of the gain or loss is immaterial. . . . [M]ost potential advisory committee recommendations pertaining to marketing status, labeling, post-marketing requirements, and device classification or reclassification would ordinarily have a "direct and predictable effect" on financial interests. . . . Financial interests that ordinarily will not be affected in a direct and predictable manner include a grant or contract between an organization and the employee's university to conduct research on a product that is not the subject of the particular matter before the advisory committee or a competitor product. (FDA, 2008b, pp. 10–14)

FDA rules involving clinical investigators also take into consideration aspects of the study design—for example, the use of objective end points, blinding, or the participation of multiple investigators—that might reduce the potential of an investigator's interests to bias the study results (21 CFR 54.5). (The rules cover financial disclosures and the management of the relationships of clinical investigators in studies that companies plan to use to support FDA approval of the marketing of a medical product.)

Management Strategies

Survey data indicate that medical schools employ various strategies to manage conflicts of interest in research (Table 3-2). Disclosure to some outside party seems to be a common and preferred response to an identi-

TABLE 3-2 Percentage of Medical Schools Citing Different Management Policy Options When Researchers Have a Significant Financial Interest in Their Research

Policies Suggested or Required by Organizations Permitting Participation After a Conflict of Interest Is Identified	Percentage of Medical Schools
Monitoring the research project	87
Eliminating the investigator's significant financial interest	83
Disclosing significant financial interests to human subjects on the consent form	86
Using either internal or external data safety monitoring boards	54
Regularly auditing the informed consent and research subject enrollment process	51
Involving a patient representative during the consent and enrollment process	26
Involving a patient representative during recruitment of research subjects	22

fied conflict of interest (see, e.g., Boyd and Bero [2000] and Ehringhaus and Korn [2004]).

One analysis of cases in which researchers disclosed their financial relationships found that university conflict of interest committees determined that 26 percent of the cases reviewed involved conflicts of interest that needed management (Boyd et al., 2004).[17] The three most commonly applied management strategies were requiring disclosure in publications and presentations (40 percent of the managed cases), appointing an oversight committee to protect the interests of students involved in the project (21 percent of the managed cases), and eliminating the relationship during the period of the project (22 percent of managed cases). The least common management approach was eliminating the conflict of interest or prohibiting the research.

The IOM committee is not familiar with any evaluations of the implementation or the consequences of different management strategies. This is a significant deficit. At one of the committee's public meetings, an experi-

[17] Financial ties were most often with pharmaceutical companies or biotechnology companies. Across the seven campuses involved in the analysis, payment for consulting activities accounted for 54 percent of the financial disclosures, equity holdings accounted for 38 percent of the disclosures, payment for talks accounted for 14 percent, scientific advisory board membership accounted for 13 percent, membership on a company's board of directors accounted for 12 percent, and being a company founder accounted for 7 percent. Over this period, investigators became more likely to have multiple financial ties with a single company, such as financial ties through the receipt of consulting income, honoraria, and stock.

enced clinical researcher questioned the strategy of appointing an oversight committee to monitor research involving an investigator with a conflict of interest (Benet, 2008). In that scientist's view, so many decisions need to be made in the course of a research project that it is not realistic to expect a faculty member to want to or have time to participate in the close and effective monitoring of another faculty member's research. In addition, monitoring imposes costs that might be judged in some cases to exceed the potential benefits.

In Chapter 9, the committee recommends the development and funding of a program of research on conflict of interest. The outcomes of conflict of interest policies, both positive and negative, would be a key issue for consideration in such a program of research.

Knowledge and Attitudes Regarding Conflict of Interest Policies

A few studies suggest that many investigators do not understand their institution's conflict of interest policies and may be skeptical about them. In one in-depth qualitative study of clinical investigators, less than half of the respondents could accurately describe their institution's policies (Boyd et al., 2003). In addition, many respondents believed that the individual investigator, the professional society, and the public at large—not the university—were the appropriate monitors of conflicts of interest. Although many respondents recognized the general risks associated with conflicts of interest, they believed that they were personally not at risk for bias resulting from financial relationships, a common finding in the research reviewed for this report.

In another, web-based survey of researchers at a single medical center (response rate of less than 40 percent), 17 percent of the respondents were not aware of the institution's conflict of interest policies and 60 percent could correctly describe at least one (but not all) of the policies (Lipton et al., 2004). With respect to consequences, 43 percent of the respondents believed that the policies discouraged a faculty member's ability to start new companies, 31 percent believed that the policies discouraged consultation with companies, and 21 percent believed that the policies discouraged sponsored research but another 21 percent thought that they encouraged such research. Although 14 percent believed that the school's policies hindered their own research agenda, 82 percent believed that it had no effect. Among the respondents who actually had a financial relationship that was subject to committee review, 91 percent said that they were satisfied with how the review was handled, but some of the remaining 9 percent who were not satisfied had very negative attitudes toward the process.

Policy Dissemination and Education Strategies

AAMC has advised academic medical centers to provide education and training about their conflict of interest policies to all faculty, staff, students, and trainees (AAMC, 2001). In 2002, NIH reported that the policies of some research institutions were difficult to locate and were sometimes interspersed in various other institutional policies on issues such as ethics, purchasing, and consulting. It recommended that institutions present their conflict of interest policy "as a complete, self-contained document with citations and web links to supporting policies, procedures, and Federal and state regulations, as appropriate" (NIH, 2002, unpaged). The Office of Extramural Research at NIH recently created an online tutorial on conflict of interest and other materials intended to help investigators understand and comply with NIH policies (the tutorial is available at http://grants.nih.gov/grants/policy/coi/).

The IOM committee's review of the policies and other information on conflict of interest from academic medical centers and universities showed that they vary considerably in the informational resources that they make available to their faculty and staff. Some schools provide online resources that are intended to help people easily find relevant institutional policies and resources (including individuals who can answer questions about the policies). Examples include the University of Minnesota, which has a web-based training module on conflict of interest (University of Minnesota, 2008), and Stanford University, which has frequently asked question units on conflict of interest and related university policies, as well as a quiz and other resources (Stanford University, undated).

A professional society may publicize its policies by publishing them in the society's journal(s). It may also make the policies accessible to the public on its website.

Compliance and Enforcement

The earlier discussion of compliance with and the enforcement of disclosure policies reviewed information about compliance with and the enforcement of policies as they apply to individuals. The discussion in this section focuses on the extent to which research institutions follow applicable PHS rules.

A 2002 review of a sample of grantee policies undertaken by the NIH Office of Extramural Research found that institutional policies often did not reflect the requirements of the PHS regulations (NIH, 2002). In 2007, NIH reported on 18 targeted site reviews regarding grantee compliance with PHS conflict of interest policies. It found no instances of intentional noncompliance and concluded that the institutions that it visited generally

had "implemented the Federal regulation thoughtfully and with diligence" (NIH, 2007). It did, however, report some problems with timely and consistent reporting and suggested the need for improvements in several areas, including educational and enforcement procedures, the clarity of the forms used to report conflicts of interest, and definitions.

A 2008 report by the OIG of the U.S. Department of Health and Human Services criticized NIH's oversight of grantee institutions (OIG, 2008). Although NIH accepted some of the report's suggestions, it rejected taking a more active oversight role, particularly requiring and reviewing detailed conflict of interest reports from institutions. Doing so would "effectively, if not legally, transfer the locus of responsibility for managing [financial conflicts of interest] from the grantee institution to the Federal Government" (Zerhouni [2008] in OIG [2008, pp. 20–21]). The OIG disagreed that collection of the information would usurp grantee responsibilities, and it argued that without some details about the nature (and not just the existence) of the conflicts that were identified, NIH lacks important information that it needs to oversee and enforce PHS regulations.

Also in 2008, NIH announced the development of and began testing an electronic reporting and tracking tool that that would allow grantee institutions to prepare and submit required conflict of interest reports and search past reports. Consistent with one of the OIG report's recommendations, the tool would also provide a central web-based location for grantee conflict of interest reports received across NIH (Bravo, 2008; see also NIH [2008b]). In addition, NIH has initiated procedures and training to ensure proper NIH staff oversight of conflict of interest issues involving grantees.

The IOM committee identified some publicly reported instances of NIH enforcement of PHS policies. For example, in October 2008, after congressional inquiries and reports of apparent major inaccuracies in a researcher's financial disclosures to Emory University, NIH suspended a $9 million grant for a study led by the researcher and instituted special conditions for the institution's other studies conducted with the support of NIH grants (Harris, 2008; Kaiser, 2008). Subsequently, the university removed the individual from his post as department chair and significantly restricted his outside activities (Shelton, 2008).

RECOMMENDATIONS

Empirical data on conflict of interest policies are limited, have methodological shortcomings, and tend to focus on academic institutions. Some institutions do not make their policies easily accessible. Institutions also revise their policies, which limits the usefulness of older studies. Nonetheless, the available evidence points to substantial variations in institutional requirements for the disclosure of financial relationships or conflicts of interest.

Variations exist in who is required to report on a conflict of interest, when reporting is required, and what relationships and what details about these relationships are to be reported (e.g., the exact amounts of payments rather than payments above a threshold or within dollar categories). Variations also exist in what relationships are prohibited, what criteria are considered in evaluating financial relationships, what strategies are employed when a conflict of interest is identified, and what is done to monitor and promote adherence to policies. These extensive variations raise concerns that some institutions may not have sufficient data to make determinations about the extent and the nature of an individual's financial relationships or to judge the severity of a conflict of interest. Some institutions may also lack adequate procedures for evaluating and eliminating or managing identified conflicts.

The committee expects that there are many explanations for the variations in policies, including the press of other issues demanding attention, a reluctance to propose changes that may spark controversy and dissension, and cultural traditions that vary in how restrictions on the pursuit of personal gain are viewed. Absent outside pressures and oversight, variation in conflict of interest policies may encourage an unhealthy competition among institutions to adopt weak policies and shirk enforcement. It may also aid investigators who want to avoid restrictions on their pursuit of secondary financial interests.

The recommendations presented in this chapter and in this report are intended to discourage such undesirable institutional and individual behavior but not to damage beneficial collaborations. If institutions do not act voluntarily to strengthen their conflict of interest policies, such inaction may prompt government regulation. (The recommendations below focus on individual conflicts of interest. Chapter 8 presents recommendations on conflicts of interest at the institutional level.)

Adopting Conflict of Interest Policies

The committee's first recommendation deals with institutional basics: the adoption of a policy and the creation of a conflict of interest committee. The details of the policies may vary, depending on an institution's mission and other characteristics, but certain features are fundamental to credible and meaningful conflict of interest policies.

RECOMMENDATION 3.1 Institutions that carry out medical research, medical education, clinical care, or practice guideline development should adopt, implement, and make public conflict of interest policies for individuals that are consistent with the other recommendations in this report. To manage identified conflicts of interest and to

monitor the implementation of management recommendations, institutions should create a conflict of interest committee. That committee should use a full range of management tools, as appropriate, including elimination of the conflicting financial interest, prohibition or restriction of involvement of the individual with a conflict of interest in the activity related to the conflict, and providing additional disclosures of the conflict of interest.

Recommendation 3.1 calls on all institutions that conduct medical research, offer medical education, provide clinical care, or develop practice guidelines to adopt comprehensive conflict of interest policies for their employees. These policies should cover all those whose decisions and judgments affect their institution's missions and primary interests. Consistent with the committee's charge, the recommendation refers only to relationships with pharmaceutical, medical device, and biotechnology companies. In practice, individual institutions will design their policies to cover other relevant relationships. These might include consulting or speaking arrangements with health insurance companies, leadership positions with professional organizations, teaching at other institutions, and service on government advisory committees. (As described in Chapter 2, some of these relationships may present conflicts of commitment.)

So that those who rely on academic medical centers, medical journals, professional societies, patient advocacy groups, and other institutions may assess an institution's conflict of interest policies, the policies should be publicly available, for example, on the institution's website. Although the details will vary, it is also important for institutions to disseminate and explain their policies to those who are subject to them. Strategies might include the provision of an education module and the inclusion of a set of frequently asked questions.

Recommendation 3.1 also calls on academic medical centers and other institutions to create conflict of interest committees to manage conflicts of interest involving individuals. This reiterates a recommendation of AAMC, which found in its 2003 survey that not all medical schools reported that they had such committees. Professional societies and other institutions would also benefit from conflict of interest committees that would implement their policies. For example, a conflict of interest committee for a professional society would review conflicts that arise in different aspects of the society's work, including the development of clinical practice guidelines and the conduct of society meetings and educational programs. (For some very small institutions, the formation of a formal committee may not be necessary if the relevant responsibilities are clearly defined and assigned to appropriate staff or, possibly, volunteers.) A conflict of interest committee should bring experience and consistency to evaluations of financial relation-

ships with industry and decisions about those relationships, although the specific details (e.g., how risks and potential benefits are assessed and what management options are considered) may vary, depending on the activity in question. The recommendation mentions monitoring as an activity of the conflict of interest committee, but in practice, the details of monitoring may best be handled by an administrative unit, with the conflict of interest committee providing more general oversight.

Improving Information for Identifying and Evaluating Conflicts of Interest

Disclosure as an Element of Policy

The disclosure of financial relationships with industry is only one part of a comprehensive conflict of interest policy, but it is nonetheless an essential step. Unless institutions know about these relationships, they cannot assess them and determine whether additional steps—such as the elimination or management of a relationship—are necessary. Recommendation 3.2 identifies key features of policies on disclosure. Recommendations in Chapters 4, 5, 6, and 7 provide guidance about the elimination or management of conflicts of interest in the contexts of medical research and education, patient care, and practice guideline development, respectively.

RECOMMENDATION 3.2 As part of their conflict of interest policies, institutions should require individuals covered by their policies, including senior institutional officials, to disclose financial relationships with pharmaceutical, medical device, and biotechnology companies to the institution on an annual basis and when an individual's situation changes significantly. The policies should

- **request disclosures that are sufficiently specific and comprehensive (with no minimum dollar threshold) to allow others to assess the severity of the conflicts;**
- **avoid unnecessary administrative burdens on individuals making disclosures; and**
- **require further disclosure, as appropriate, for example, to the conflict of interest committee, the institutional review board, and the contracts and grants office.**

Conflict of interest policies should cover individuals who have discretion in the conduct of research and educational activities, the provision of clinical care, and the development of clinical practice guidelines. (Senior officials are also covered by Recommendation 8.1 in Chapter 8, which examines institutional conflicts of interest.) Disclosures should be made

at least annually and more often if an individual's situation changes. They should also be updated during the year if an individual's situation changes significantly, for example, because an existing relationship expands (e.g., a faculty member who is a company consultant is also appointed to the company's governing board) or because a new relationship (e.g., a new consulting arrangement) is created that is relevant to a specific activity (e.g., participation in a panel developing a clinical practice guideline). In addition to requiring disclosure of conflicts of interest to the institutional review board and the other entities listed in the recommendation, policies may also cover additional disclosures, for example, to entities responsible for continuing medical education program oversight.

Elements of a disclosure policy may vary depending on the institution, but the disclosures should be sufficiently specific to support the identification of conflicts of interest and an evaluation of their severity. For example, if information on the dollar value of relationships is reported in categories rather than specific amounts, the highest categories should reach into the hundreds of thousands of dollars. The committee recommends the elimination of minimum thresholds for individual reporting of financial relationships. As discussed earlier in this chapter, the 1995 PHS regulations specify a $10,000 threshold, which applies to the individual and his or her spouse and dependent children. Most PHS grantees have adopted this threshold, although approximately one-quarter require reporting regardless of the dollar value of the relationship. The committee recognizes that elimination of the minimum threshold would add to the burden both for those reporting and for those reviewing relationships but believes that it is important to increase the accuracy of reporting and provide institutions with a more complete picture of an individual's financial relationships across different reporting categories (e.g., consulting, advisory committee service, and speaking). The committee also notes research that suggests that even small payments may put an individual at risk of unconscious bias. In their joint report on conflict of interest in human subjects research, AAMC and AAU also recommended removing minimum (de minimis) thresholds (AAMC-AAU, 2008). NIH should seek revisions in the PHS regulations to eliminate the threshold, but NIH grantees should act without waiting for such revisions.

Greater Consistency in Disclosure Policies

The committee recognizes that the objective of achieving sufficient specificity in disclosures may sometimes be in tension with the objective of minimizing the administrative burdens of disclosure. To the extent that the consensus process proposed in Recommendation 3.3 is successful, it may help resolve these tensions by promoting greater consistency across institutions. Greater consistency should simplify the demands on those who

must understand and comply with the disclosure requirements of multiple institutions.

RECOMMENDATION 3.3 National organizations that represent academic medical centers, other health care providers, and physicians and researchers should convene a broad-based consensus development process to establish a standard content, a standard format, and standard procedures for the disclosure of financial relationships with industry.

To achieve greater consistency in institutional disclosure requirements, Recommendation 3.1 calls for a broad-based national consensus development process. This undertaking would be convened by national organizations representing academic medical centers, other health care providers, physicians, and researchers and would also include representatives of professional societies; consumer and patient advocacy groups; accreditation, certification, and licensing agencies; medical journals and organizations of medical journal editors; health plans and insurers; government agencies, including NIH and the FDA; and organizations with expertise in database development and management. The process used by AAMC to develop its recent recommendations on relationships with industry in medical education offers one model for the process, although the task would be narrower and more detailed in its focus on definitions of the financial relationships to be disclosed, reporting formats, and similar matters.

The committee appreciates that different disclosures may be required for different purposes. For example, the information that a medical journal needs from the authors of a manuscript differs from the information that a government agency may require for members of an advisory panel. For similar institutions (e.g., for medical journals as a category and for similar government advisory panels as a category), the objective would be to develop a consensus on a common format.

A major task for the consensus development process would be to agree on the categories of relationships that need to be disclosed and the type of information about each relationship that is needed to evaluate it. Consulting is an example of a category that needs further specification. That term can cover relationships that range from the provision of promotional or marketing support to a company to the offering of objective technical advice on scientific advances, products in development, or research study design. The institution of standard categories, definitions, and similar agreements should reduce confusion, misunderstandings, and misinterpretations.

In technical terms, the task for the consensus group would be to specify the elements for a relational database, including the definitions and attributes of these elements. Once the elements are specified, the expectation is that software developers would create programs that physicians and

TABLE 3-3 Candidate List of Categories of Financial Relationships with Industry to Be Disclosed

Research grants and contracts
Consulting agreements
Participation in speakers bureaus
Honoraria
Intellectual property, including patents, royalties, licensing fees
Stock, options, warrants, and other ownership (excepting general mutual funds)
Position with a company
Company governing boards
Technical advisory committees, scientific advisory boards, and marketing panels
Company employee or officer, full or part time
Authorship of publications prepared by others
Expert witness for a plaintiff or a defendant
Other payments or financial relationships

researchers could use on their computers to enter, store, and update information on their financial relationships. The software would then format the information as needed for disclosures for various purposes (e.g., submission to an academic medical center or a medical journal). It would be similar to reference software that allows authors to format references to meet the specifications of different journals.

As a starting point, Table 3-3 presents a candidate list of basic categories of the relationships to be disclosed. Each requires further definitions, and some might require subcategories. The committee did not propose a specific format for the provision of information about these relationships. It is important, however, that any format promote completeness and specificity, for example, by requiring individuals to check one box if they have a particular relationship, to check another box to declare explicitly that they do not have the relationship, and to provide certain details about an indicated relationship (e.g., its value, the company involved, and the nature of the work).

In addition to the categories of relationships to be disclosed, the consensus process needs to address several other key questions. For example, what details of relationships need to be reported (e.g., the amount of income and the name of the company)? How should amounts be reported? Would it be preferable to have individuals making disclosures check a box indicating the range of income from a relationship or should they provide specific dollar amounts? Will a single time frame (e.g., the relationships in existence during the previous 12 months) be adequate for all purposes? How should the financial relationships of close family members (e.g., spouses or domestic partners, dependent children, and parents) be considered?

Company Reporting of Payments to Individuals and Institutions

Recommendations 3.2 and 3.3 involve disclosures by individuals to organizations. The next recommendation proposes requirements for companies. Several state laws and proposals for additional state or federal rules reflect concerns about inaccurate and incomplete disclosures. As discussed earlier, these laws and proposals vary, for example, in the types of companies and payments or relationships that they cover and in provisions for public reporting. In response to proposals for additional state and national legislation, several industry groups and individual companies have supported some form of company disclosure while seeking to minimize the administrative burdens of such reporting and to protect information that might reveal business strategies to competitors (Finance Committee, U.S. Senate, 2008). Recommendation 3.4 calls for a broad national reporting program.

RECOMMENDATION 3.4 The U.S. Congress should create a national program that requires pharmaceutical, medical device, and biotechnology companies and their foundations to publicly report payments to physicians and other prescribers, biomedical researchers, health care institutions, professional societies, patient advocacy and disease-specific groups, providers of continuing medical education, and foundations created by any of these entities. Until the Congress acts, companies should voluntarily adopt such reporting.

A national law covering company payments to physicians, researchers, and medical institutions would be a useful supplement to policies that require individual physicians, researchers, and others to disclose financial relationships to institutions. It should provide that company-reported payments be readily available on a searchable public website that allows the aggregation of all payments made to an individual or organization, although some personal identifying information might be restricted to protect individuals against, for example, identity theft. Such a database could help institutions and potentially others to monitor adherence to institutional disclosure policies. It would not substitute for institutional conflict of interest policies. It also would not eliminate conflicts of interest. One objective of drafting and implementing legislation and explaining it to the public and those affected would be to discourage the inference that all reported relationships are bad and to avoid harm to constructive collaborations.

The committee did not investigate program options and administration in detail, but it generally supports the approach to company reporting discussed by MedPAC during several public sessions in 2008 and presented in MedPAC's March 2009 report (MedPAC, 2008a,b,c,d, 2009). Consistent

with the committee's recommendation but in contrast to state policies and some other proposals for federal policy, MedPAC's proposal covers not only payments to physicians but also payments to a range of organizations, including medical schools, professional societies, and providers of continuing medical education. The committee's proposal would add payments to biomedical researchers. The MedPAC recommendation would add payments to pharmacies and pharmacists, health plans, and pharmacy benefit managers as well as payments by medical supply companies. Companies could include clarifying details about the context of a payment (e.g., specifying whether the payment is a research grant that covers all project costs and not just the investigator's salary). The committee considers these to be reasonable provisions for a company reporting program.

Implementing regulations would need to specify clear definitions and exact categories for the reporting of payments. The consensus-building activity proposed in Recommendation 3.3 could contribute to this specification and promote consistency with institutional disclosure policies.

As proposed by MedPAC, the database of company-reported information would be public, but the physician's National Provider Identifier (NPI) would not be given.[18] The entire database would be available to researchers who enter into confidentiality and data use agreements with the secretary of the U.S. Department of Health and Human Services. The database would be searchable by manufacturer; recipient name, location, and specialty (if applicable); type of payment; name of related product (if applicable); and year. The MedPAC report did not include an estimate of the costs to the government of creating and maintaining the systems but notes that the costs would be higher than those of state systems, only one of which makes the data public, but not in a searchable database.

In MedPAC's proposal, company reporting would be required annually, but reporting for a clinical trial could be delayed until the trial was publicly registered or until FDA approval related to the development of a new product was granted (but not later than 2 years after the payments were made). The national policy would preempt state policies, to the extent that they cover the same categories of payments and recipients, and would provide for civil penalties for noncompliance. Legislation introduced in the U.S. Congress in 2009 includes similar provisions on these points (Grassley, 2009).

In addition to the proposal on company reporting, MedPAC has also proposed that the Congress require hospitals and other providers to report (and the government to post on a public website) on physicians' direct

[18] The NPI is a unique number mandated by the U.S. government for most U.S. physicians that is available in a publicly accessible database that links it to the physician's name, practice location, business office location, license numbers, and other identifiers.

or indirect ownership shares in the facility (MedPAC, 2009; see further discussion in Chapter 6). The provision of recommendations on conflicts of interest arising from physician ownership of facilities was outside this committee's charge. The reporting program proposed by MedPAC would make considerable additional information available to researchers, patients, and others.

A discussion of the pros and cons of establishing a broader system of disclosure is presented in Appendix F.

Recommendations in the Following Chapters

The recommendations in this chapter call for institutions to adopt conflict of interest policies consistent with the recommendations in this report and for individual and cooperative institutional efforts and legislative actions to strengthen policies on the disclosure of individual and institutional financial relationships with industry. The next four chapters of this report offer additional recommendations related to policies and practices in the specific areas of medical research, medical education, patient care, and the development of clinical practice guidelines. Chapter 4 calls for institutions to generally bar researchers with a conflict of interest from conducting research with human participants except when the investigator's expertise is essential to the safe and rigorous conduct of the research. Chapters 5 and 6, among other recommendations, call for physicians and researchers to forgo and institutions to prohibit or end certain relationships with industry that present unacceptable risks of undue influence over professional decision making or a loss of public trust.

Chapter 7 includes recommendations for reducing industry influence in the development of clinical practice guidelines and increasing the levels of disclosure of organizational and individual financial relationships. Chapter 8 recommends that institutions establish policies at the board level to identify, limit, and manage institution-level conflicts of interest. The final chapter calls for a range of organizations to develop incentives to promote the institutional adoption and implementation of the policies recommended here. It also calls for the development of a research agenda to evaluate and guide improvements in conflict of interest policies and procedures.

4

Conflicts of Interest in Biomedical Research

Biomedical research provides discoveries that may lead to new or better tests and treatments that improve individual and public health. Patients, patients' families, physicians, other researchers, and policy makers need to trust that the design, conduct, and reporting of such research are unbiased and that the time and effort that they contribute to research will be used to advance science. Participants in clinical trials need to trust that they are not exposed to unnecessary risk. Conflict of interest policies should not only address concerns that financial relationships with industry may lead to bias or a loss of trust but should also consider the potential benefits of such relationships in specific situations.

Research partnerships among industry, academia, and government are essential to the discovery and development of new medications and medical devices that provide improved means for the prevention, diagnosis, and treatment of health problems. Historically, the federal government has taken the lead in supporting discoveries in basic science, whereas commercial firms have focused on the discovery of specific medicines and then their development through clinical trials to the regulatory approval of marketable products. (As discussed below, the development pathway for medical devices often differs from the pathway for pharmaceuticals.) Before 1980, the federal government held the patents resulting from publicly funded basic research, but very few patents were licensed for commercial development. In 1980, the U.S. Congress passed the Patent and Trademark Amendments of 1980 (P.L. 96-517, commonly known as the Bayh-Dole Act, after its sponsors). The law allowed institutions to patent discoveries resulting from federally funded research and to grant licenses for others to develop those discoveries. Universities may retain licensing and royalty fees, which they generally share with their scientists who developed the

patented discovery. Since the law's passage, patent licensing and other financial relationships linking medical researchers and research institutions with industry have expanded substantially (Schacht, 2008). Some scholars, however, have pointed to factors in addition to the legislation that may be associated with the historical increase in the numbers of patents, including a broadening of the criteria that allow materials to be patentable (particularly for life forms) and advances in biomedical research (see, e.g., Mowery et al. [2001, 2004] and Sampat [2006]; see also *Diamond v. Chakrabarty*, 447 U.S. 303 [1980]).

This chapter starts with a brief overview of some dimensions of university-industry collaborations in biomedical research and then summarizes data on the extent of the relationships between pharmaceutical, device, and biotechnology companies and academic research institutions and individual researchers. The next sections review concerns about these relationships and responses to those concerns. (Appendix E provides an additional discussion of the nature and importance of academic-industry collaboration in medical research.) Because many conflicts of interest at the institutional level emerge from research discoveries, the discussion of these conflicts and the responses to them presented in Chapter 8 is also relevant. The final section of this chapter offers recommendations.

COLLABORATION AND DISCOVERY IN BIOMEDICINE

The path from a scientific discovery to the marketing of a new drug, device, or biological product is typically long and complex and involves a diversity of expertise and resources. For example, basic researchers, often at academic medical centers and other research institutions, can identify new potential targets for therapies and new strategies for treatment, suggest additional diseases that may be able to be treated by existing and newly developed compounds, and suggest both how to target therapies to the patients who are the most likely to benefit and how to avoid particular treatments for patients at high risk for adverse events from those treatments. Scientists at the National Institutes of Health (NIH) also contribute to the discovery process, and important clinical research is undertaken at the NIH Clinical Center. In addition, basic scientists at biotechnology and pharmaceutical companies have made fundamental discoveries that have led to new therapies.

Scientists at pharmaceutical companies can help identify or develop drugs that may be active against new biological targets that have been identified by individuals who conduct basic research. These companies also have the critical ability to use good manufacturing practices to produce a candidate drug in sufficient quantities for clinical trials and then for large-scale commercial distribution, if the product is approved for marketing.

Furthermore, they have experience with the Food and Drug Administration (FDA) drug approval process, which includes extensive requirements for preclinical and clinical testing and for manufacturing. Finally, pharmaceutical companies also supply or raise the capital needed to fund the lengthy process of bringing a product to market. Medical device companies and biotechnology companies play analogous roles in translating discoveries made through basic research into products or services for medical and public health practice, although the specific details differ from those involved with the drug approval process. (Appendix E provides a more detailed discussion of the discovery and development process.)

The committee heard testimony that collaboration between academic and industry researchers in the drug discovery process can be mutually beneficial (Benet, 2008; Cassell, 2008). When a new disease mechanism is discovered, academic and industry scientists can work together to identify promising therapeutic targets and treatment approaches. Furthermore, academic researchers can inform industry when they identify potential new targets for chemical intervention. Drug companies can then quickly scan their chemical libraries to search for compounds with potential biological activity and describe what problems they have encountered as they have tried to identify the specific targets of those compounds. This begins the long process of applied chemistry, which is needed to identify a candidate drug.

Many examples illustrate that academic collaboration with pharmaceutical and biotechnology companies can lead to dramatic therapeutic advances that save lives and improve the quality of life. Particularly dramatic are those related to therapies for human immunodeficiency virus (HIV) infection. Collaborations contributed to delineation of the pathophysiology of the disease and the development of successive new classes of drugs, including reverse transcriptase inhibitors, protease inhibitors, and entry inhibitors (Braunwald et al., 2001). These advances have transformed a uniformly fatal illness into a chronic disease that people are now generally able to survive for decades. A few other examples include the following:

- an anticoagulant (abciximab), which is a monoclonal antibody against the platelet glycoprotein IIb/IIIa, that has been shown to prevent thrombotic complications of coronary angioplasty (EPIC Investigators, 1994; Tcheng et al., 2003);
- pulmonary surfactant, which improves survival in neonates with respiratory distress syndrome and which was developed by a number of academic researchers at different universities working in close collaboration with several pharmaceutical companies (personal communication, Jeffrey A. Whitsett, Chief, Section of Neonatology, Perinatal and Pulmonary Biology, Cincinnati Children's Hospital Medical Center, December 9, 2008);

- rituximab, a monoclonal antibody against the CD20 marker on B cells, which is effective in patients with certain types of lymphoma and leukemia, rheumatoid arthritis, and multiple sclerosis and in preventing the rejection of transplanted organs (Maloney et al., 1997; Edwards et al., 2004; Hauser et al., 2008);
- bortezomib, a proteasome inhibitor, which improves survival in patients with multiple myeloma (San Miguel et al., 2008); and
- imatinib, a tyrosine kinase inhibitor, which has greatly prolonged the survival of patients with chronic myelogenous leukemia (Druker et al., 2006).

Compared with the drug development process, the development of complex medical devices tends to be a more continuous process of innovation and refinement that involves frequent alterations in device design, materials, manufacturing processes, or other characteristics. Examples of medical devices that have been developed as a result of close academic-industry collaborations include implanted defibrillators (Jeffrey, 2001), prosthetic heart values (Gott et al., 2003), and mechanical ventilators (Keszler and Durand, 2001). Advances in many technologies, such as pulse oximetry for the monitoring of anesthesia and phototherapy for the treatment of disease, highlight the results that may accrue from a combination of research collaboration and communication with senior clinicians about their experiences (Mike et al., 1996; Dicken et al., 2000; McDonagh, 2001; Severinghaus, 2007; Vreman et al., 2008).

Nevertheless, advances in medical devices may result in conflicts of interest. For example, the process of device refinement (particularly when the refinements are minor or are not associated with well-designed clinical studies) is at the center of controversies over whether some consulting arrangements between orthopedic surgeons and the manufacturers of orthopedic devices represent fair payments for technical services or are inducements for the surgeons to use the device.

To promote further progress in moving discoveries from basic science into successful products, NIH has developed major initiatives to strengthen early translational research, which focuses on transforming specific discoveries into clinically useful products or services (see, e.g., NIH [2008d] and CTSA [2009]). At academic centers, this research may involve populations of individuals with rare diseases or biological agents that do not have obvious commercial potential. Such research may, nonetheless, lay the foundation for companies to develop successful products or at least for company licensing of compounds or agents for which university research has provided proof-of-concept data but for which companies must take the next steps.

INDUSTRY FUNDING AND RELATIONSHIPS IN BIOMEDICAL RESEARCH

Growth and Magnitude of Industry Funding

Industry funding for biomedical research has been growing in recent decades and is now the largest source of funding for such research in the United States. Between 1977 and 1989, the proportion of the total funding for clinical and nonclinical research supplied by industry grew from 29 to 45 percent (Read and Campbell, 1988; Read and Lee, 1994). Between 1995 and 2003, the yearly figures (which are based on sources of information somewhat different from those for 1977 to 1985) ranged from 57 to 61 percent (Moses et al., 2005; see also Hampson et al. [2008]). This funding supports work in the laboratories of pharmaceutical, device, and biotechnology companies; contracts for research conducted by universities and other nonprofit research institutions; and contracts with commercial contract research organizations that carry out clinical trials in academic and private practice settings.

Extent of Academic-Industry Relationships

Industry relationships with academic biomedical researchers are extensive. A 2006 national survey of department chairs in medical schools and large independent teaching hospitals found that 67 percent of academic departments (as administrative units) had relationships with industry (Campbell et al., 2007b). In addition, 27 percent of nonclinical departments and 16 percent of clinical departments received income from intellectual property licensing. Among the department chairs, 60 percent had relationships with industry, including serving as a consultant (27 percent), a member of a scientific advisory board (27 percent), a paid speaker (14 percent), an officer (7 percent), a founder (9 percent), or a board member (11 percent) for a company. In some universities, companies fund individual departments, multidisciplinary research centers, or campuswide research programs (Bero, 2008).

For individual academic researchers, studies from the 1990s show that they have widespread relationships with industry. In a 1996 survey, 28 percent of life sciences faculty who conducted research received support from industry sources (Blumenthal et al., 1996a,b). The prevalence of support was greater for researchers in clinical departments (36 percent) than for those in nonclinical departments (21 percent). In a 1998 study, 43 percent of academic scientists in the 50 most research intensive universities reported receiving research-related gifts (independent of a research grant or contract) during the preceding 3 years (Campbell et al., 1998). The most

widely reported gifts received from industry were biomaterials used in research (24 percent),[1] discretionary funds (15 percent), research equipment (11 percent), and trips to professional meetings (11 percent). Among those receiving gifts, 66 percent viewed them as important to their research.

A study of disclosures at the University of California at San Francisco found that by 1999, approximately 8 percent of principal investigators at the institution reported personal financial ties to the sponsor of a particular research project (Boyd and Bero, 2000). Thirty-four percent of these involved temporary speaking engagements, 33 percent involved consulting relationships, 32 percent involved paid positions on a scientific advisory board or board of directors, and 14 percent involved equity in a firm (more than one type of involvement for a single research project was possible).

Although evidence is limited and not recent, some research suggests that faculty members who have research relationships with industry are more productive in certain respects than faculty who do not have such relationships. One study found that researchers in the former group are significantly more likely than researchers in the latter group to report that they are involved with a start-up company (14 versus 6 percent) or that they have applied for a patent (42 versus 24 percent), have had a patent granted (25 versus 13 percent), have a patent licensed (18 versus 9 percent), have a product under review (27 versus 5 percent), or have a product on the market (26 versus 11 percent) (Blumenthal et al., 1996a). That study also reported that these faculty reported that they had published significantly more articles in peer-reviewed journals in the previous 3 years than faculty without industry funding (15 versus 10 articles) (Blumenthal et al., 1996a). In general, a greater number of biomedical patents should benefit society, since patents are usually a key step in the development of new therapies or diagnostic tests. Likewise, greater publication productivity should, in general, advance scientific knowledge.

The associations reported above do not prove causality. Industry may fund scientists who are more productive or whose research has more commercial potential. Alternatively, industry may provide funding that allows scientists to be more successful commercially and academically, or such support may encourage funded scientists to be more active commercially.

CONCERNS ABOUT RELATIONSHIPS WITH INDUSTRY

Despite their benefits, relationships with industry create conflicts of interest that can undermine the primary goals of medical research. Where

[1] One reviewer of the report observed that companies view the provision of these proprietary materials as a service to the academic community and that they may, in any case, not have a mechanism for charging for them.

there are conflicts, legitimate and serious concerns can be raised about the openness of research and potential bias in the design, conduct, and reporting of research (see, e.g., Gross [2007]). Whether or not the conflicts actually lead to unwarranted secrecy or biased results in particular cases, they have the potential to threaten the reputation of the research enterprise if they are not avoided or identified and managed responsibly.

The review below does not cover marketing activities disguised as research, in particular, so-called seeding trials that companies design to change the prescribing habits of participating physicians rather than to gather scientifically valid information. These studies, which potentially expose study participants to risk without investigating scientifically significant questions, are discussed in Chapter 6.

Industry Funding of Research and Reduced Openness in Science

A fundamental tenet of academic science is that information, data, and materials should be shared. Such sharing could be at risk in academic-industry collaborations. A 2003 National Research Council report identified "the commercial and other interests of authors in their research data and materials" as major obstacles to information sharing (NRC, 2003, p. 1).

A 1995 survey of life sciences faculty in the 50 most research intensive institutions found that 14 percent of those with funding from industry reported that trade secrets had resulted from their research, whereas 5 percent of those without funding from industry did so (Blumenthal et al., 1996a). Trade secrets were defined as information that is kept secret to protect its commercial value. In some cases, this finding may represent the normal and necessary protection of key information prior to the filing of a patent on intellectual property, with the resulting enhanced opportunity for successful commercialization. (Unlike trade secrets, patents require the disclosure of information but protect property interests in a discovery for a defined period.) A 1993 study of academic genetics research found that faculty with research funding from industry were significantly more likely to delay publication of their research results by more than 6 months to allow the commercialization of their research (Blumenthal et al., 1997).

The situation may have changed since the 1993 study cited above because some basic science journals have adopted more stringent policies on data sharing and withholding (see, e.g., NRC [2003], NPG [2007], and Piwowar and Chapman [2008]). In any case, not only journals but also the research institutions themselves could better maintain the integrity of research to the extent that they adopt more stringent policies on data sharing.

A related concern involves access to data. In some industry-supported research, the investigator lacks full access to the study data and depends

almost entirely on company statisticians for analysis (Bombardier et al., 2000; Silverstein et al., 2000; Curfman et al., 2005). The conflict in such situations raises reasonable concerns about the integrity of the data. To address this problem, some journals have recently decided not to publish the results of studies funded by industry unless there is full access to the data and independent repetition of the data analyses by academicians or government employees not affiliated with the sponsor (DeAngelis et al., 2001). In addition, many universities have recently added a requirement for access to study data to the terms of their research contracts with industry.

Research Funding from Industry and Pro-Industry Findings in Published Research

Several systematic reviews and other studies provide substantial evidence that clinical trials with industry ties are more likely to have results that favor industry. One meta-analysis found that clinical trials in which a drug manufacturer sponsors clinical trials or the investigators have financial relationships with manufacturers are 3.6 times more likely to find that the drug tested was effective compared to studies without such ties (Bekelman et al., 2003).[2] Another meta-analysis that included non-English-language studies found that studies that favored a drug were four times more likely to be funded by the maker of the drug than any other sponsor (Lexchin et al., 2003). A more recent literature review found that 17 of 19 studies published since the preceding two meta-analyses reported "an association, typically a strong one, between industry support and published pro-industry results" (Sismondo, 2008, p. 112). Similarly, another review found that industry-funded studies were more likely than other studies to conclude that a drug was safe, even for studies that found a statistically significant increase in adverse events for the experimental drug (Golder and Loke, 2008).

In addition, a study of materials submitted to the FDA in support of successful new drug applications found that clinical trials with statistically favorable results were almost twice as likely to be published as industry-funded studies that did not have favorable results (Lee et al., 2008). Overall, the results of more than half of clinical trials submitted to the FDA in support of a new drug application remained unpublished more than 5 years

[2] "A study was included if it met the following criteria: (1) its stated primary or secondary purpose was to assess the extent, impact, or management of financial relationships among industry, investigators, or academic institutions; (2) it contained a section describing study methods; (3) it was written in English; and (4) it was published following the passage of the Bayh-Dole Act of 1989" (Bekelman et al., 2003, p. 455). "The main outcomes were the prevalence of specific types of industry relationships, the relation between industry sponsorship and study outcome or investigator behavior, and the process for disclosure, review, and management of financial conflicts of interest" (p. 454).

after approval of the drug. Furthermore, comparisons of information submitted to regulatory agencies with information on the same trials published in the medical literature have found changes in the ways that the results of the trials were reported so that the published results appeared to be more favorable than the results reviewed by regulatory agencies. Such selective reporting of trial results includes additions of favorable outcomes, deletions of unfavorable outcomes, and changes in the statistical significance of the outcomes reported (Hemminki, 1980; Melander et al., 2003; Chan et al., 2004a; Rising et al., 2008; Turner et al., 2008). Recent requirements for web-based reporting of clinical trial results are described below.

Other studies have found that research funded by industry was more likely to report conclusions that favored the sponsor's drug, even if the results did not in fact support such conclusions. For example, studies that have examined clinical trials involving specific clinical specialties or particular clinical problems have found an association between industry sponsorship and results that favor industry. Examples include clinical trials of statins for the treatment of elevated cholesterol levels (Bero et al., 2007), breast cancer studies (Peppercorn et al., 2007), clinical trials of new antipsychotic drugs (Heres et al., 2006), and various nutrition-related studies (Lesser et al., 2007; see also Perlis et al. [2005]).

Several possible explanations can be offered for the association between industry support and results that are favorable to the sponsor. First, pharmaceutical and biotechnology companies seek to invest in products that will be shown to be effective and safe; hence, compounds that enter clinical trials have been selected as being likely to succeed. (That is, for-profit companies may be more risk adverse than nonprofit sponsors and fund mostly studies that seem likely to produce favorable results.) Second, investigators might have become persuaded by their own research that a drug is efficacious and, as a result, develop financial relationships with trial sponsors to help promote the future clinical development or use of the drug. Third, industry studies might be less rigorously designed or designed in a way that will bias the findings in favor of a drug, leading to false-positive conclusions that an intervention is effective, or they might be well designed but not actually conducted according to the protocol (Bero and Rennie, 1996; Steinman et al., 2006). Fourth, sponsors may be more likely to fully publish the results of studies with favorable findings (Rising et al., 2008).

The findings of three systematic reviews do not support the suggestion that industry-sponsored trials are poorly designed. They concluded that the quality of industry-sponsored trials is comparable to that of studies funded by other sources (Bekelman et al., 2003; Lexchin et al., 2003; Hampson et al., 2008). The methodologies used in those assessments of the quality of trials did not, however, take into account such issues as the appropriateness of the control intervention, the clinical relevance of the research question,

and whether the findings of the studies were fully published (Lexchin et al., 2003; Hampson et al., 2008).

In addition, it is sometimes suggested that journals prefer to publish articles that report positive findings rather than equivocal or nonexistent relationships. Several studies, based on self-reports from the authors of unpublished studies, suggest instead that authors' decisions to not submit manuscripts with the findings of their studies account for the majority of unpublished studies (Dickersin et al., 1987, 1992; Dickersin, 1990; Easterbrook et al., 1991). Similarly, a more recent study—based on inquiries to investigators about trial results that were not published—suggested that "studies were not published because they were not submitted" (Rising et al., 2008, p. 1568).

Box 4-1 summarizes several incidents that have added to concerns about bias in the reporting of industry-funded studies. Most involve an alleged failure to publish negative findings from industry-sponsored clinical trials or long delays in publication. These incidents involved a number of pharmaceutical companies and different types of drugs. Sometimes the information became known only after legal proceedings led to the disclosure of confidential internal industry documents.

In addition, systematic reviews that look at meta-analyses rather than individual clinical trials as the unit of analysis also find an association between industry funding and conclusions that favor the sponsor's product. One study found that industry-supported reviews had more favorable conclusions, noted fewer reservations about the methodological limitations of the trials included, and were less transparent than reviews conducted by the Cochrane Collaboration.[3] All seven industry-sponsored reviews recommended the experimental drug without reservation, whereas none of the Cochrane Collaboration reviews did (Jorgensen et al., 2006). Another study, a review of meta-analyses of clinical trials of treatments for hypertension, found that meta-analyses conducted by individuals with financial ties to a single drug company were not more likely than meta-analyses conducted by individuals who received funding from other sources to have results that favored the sponsor's drug. Financial ties to a single company were, however, associated with favorable conclusions by the authors of the meta-analyses. Among meta-analyses conducted by individuals with financial ties to one drug company, 27 of 49 (55 percent) reported favorable *results* from the meta-analysis, but 45 of 49 (92 percent) reported favorable

[3] The Cochrane Collaboration describes itself as "an independent, nonprofit, international organization that develops and disseminates systematic reviews of health care interventions and promotes the creation and use of evidence to guide clinical and policy decisions" (see http://www.cochrane.org/docs/descrip.htm). It relies primarily on volunteers who conduct reviews according to specific standards. It has policies intended to limit bias and restrict financial conflicts of interest in its activities.

BOX 4-1
Examples of Biased Reporting in Clinical Research

In a pivotal trial of celecoxib for treatment of arthritis, only data on outcomes at 6 months were presented, even though the original protocol called for the trial to be of a longer duration and the outcomes at 12 months were available when the manuscript was submitted (Hrachovec and Mora, 2001). The outcomes at 6 months showed an advantage for the study drug, but the outcomes at 12 months showed no advantage compared with the use of the control drugs (Wright et al., 2001).

Published clinical trials suggest that selective serotonin reuptake inhibitors have a favorable benefit-risk profile in children with depression. When unpublished data were considered, the evidence indicated that the risks appeared to outweigh the benefits for all but one drug in this class (Whittington et al., 2004).

The results of trials of paroxetine that demonstrated an increased risk of teenage suicide or a lack of efficacy were not published. The data were revealed only after a lawsuit was brought against the manufacturer (Gibson, 2004).

The manufacturer of aprotinin, an antifibrinolytic drug used in cardiac surgery to decrease bleeding, withheld data that use of the drug increased the risk of renal failure, heart attack, and congestive heart failure (Avorn, 2006).

The results of a clinical trial that compared the use of ezetimibe plus a statin with the use of a statin alone in individuals with elevated cholesterol levels were not published until 2 years after the conclusion of the trial. The results showed no difference in carotid artery wall thickness in the two groups (Kastelein et al., 2008).

The results of a pivotal clinical trial of a blood substitute (PolyHeme) in patients undergoing elective vascular surgery were not released for 5 years after the trial was stopped by the sponsor. The trial showed significant increases in the rates of mortality and heart attacks in the group receiving the experimental intervention (Burton, 2006; Northfield Laboratories, 2006).

The manufacturer of an implantable cardioverter-defibrillator allegedly failed to report critical, potentially fatal design defects for more than 3 years (Hauser and Maron, 2005).

The manufacturer of a novel immune modulator for the treatment of HIV infection refused to provide a complete set of data to the investigators in a randomized clinical trial that showed that the investigational agent was ineffective (Kahn et al., 2000).

The manufacturer of a brand-name thyroid hormone attempted to block the publication of an article showing that a generic thyroid replacement therapy had bioavailability similar to that of the brand-name preparation (Rennie, 1997).

conclusions. The authors of the review suggested that there was a "discordance between the data that underlie the results and the interpretation of these data in the conclusions" (Yank et al., 2007, p. 1204).

Thus, although there is little direct evidence that industry sponsorship has led to deliberate skewing of the results or reporting, there are multiple cases in which industry sponsors have withheld important study results and in which the conclusions presented in the reports appear to overstate the study findings. The risk of undue influence in research exists. The risk is particularly relevant in clinical trials, when the prospect of direct harm to patients (as well as research participants) is a more immediate concern than is the case for most nonclinical research. In this case, conflict of interest policies may help prevent an erosion in public confidence beyond that which may result from research that documents bias or the withholding of data.

Ghostwritten research articles also raise concerns about bias as well as the ethics of author attribution. A conflict of interest is inherent in this practice when the industry sponsor has more control over the article than the nominal authors. Chapter 5 discusses ghostwriting and also participation on speakers bureaus and recommends that academic medical centers forbid faculty from accepting the authorship of ghostwritten articles and participation in speakers bureaus.

Terms of Research Contracts

Some academic health centers allow provisions in research contracts that give industry sponsors important control over the reporting of research findings. In a 2004 survey involving academic medical centers, 7 percent of respondents reported that their institution would allow industry sponsors to revise manuscripts or decide whether results should be published, and more than 5 percent reported that they were unsure about the answers to both questions (Mello et al., 2005a). Half allowed the sponsor to draft the manuscript, whereas only 40 percent prohibited that practice. Seventeen percent of the responding institutions reported disputes over control or access to the data from research. Such disputes also figured in some of the incidents cited in Box 4-1 (see, e.g., Rennie [1997] and Kahn et al. [2000]).

Funding arrangements with contract research organizations have also raised concerns about inappropriate control by industry sponsors (Bodenheimer, 2000; Mirowski and Van Horn, 2005; Shuchman, 2007; Lenzer, 2008). For example, the International Committee of Medical Journal Editors (ICMJE) has expressed concern about the role of contract research organizations that conduct the majority of industry-funded trials, often without the protections that many university research contracts require, including rights of access to the source data and rights to publica-

tion (Davidoff et al., 2001). Although the committee found no systematic assessments or comparisons of bias in research conducted by these organizations, any lack of such controls over unilateral industry influence raises concerns.

Issues Involving Research Participants or Students

As Chapter 3 discussed, academic medical centers vary in their policies on disclosure to research participants of investigator's conflicts of interest. It also noted that several surveys suggest that participants in clinical trials currently are not highly concerned about investigators' financial conflicts of interest. Most respondents report that their decision to enroll in a clinical trial would not be greatly affected by learning that the researcher had a financial relationship with the sponsor. Some respondents even believed that "a greater financial interest would make the investigator do a better job" (Weinfurt et al., 2006a, p. 903).

It is not clear, however, whether participants in clinical trials understand how conflicts of interest could potentially compromise study designs and the protection of research subjects or how they could contribute to bias in the reporting of the results—with the possible consequence being harm to future patients. Furthermore, it is not clear that it is reasonable to expect the average participant to understand these issues. In any case, even if research subjects are not worried about conflicts of interest, other important members of the public may be concerned. As noted in earlier chapters, the political and economic support of the research enterprise depends critically on the confidence of the opinion leaders in government, the media, and academia. When they have doubts about the integrity of the enterprise, that essential support may begin to erode.

Concerns have also been raised about how researcher conflicts of interest might affect their advice about or supervision of the research of medical students, residents, fellows, and junior faculty (AAMC, 2008b; AAMC-AAU, 2008). For example, in their recent report on conflict of interest policies in human subjects research, the American Association of Medical Colleges (AAMC) and the Association of American Universities (AAU) noted the potential for the exploitation of these individuals by conflicted senior investigators or advisers. Such exploitation is unethical and also has the potential to bias the design, conduct, and findings of research. Areas that may raise problems with undue influence include decisions about an individual's inclusion or exclusion from a research project; the focus, design, and conduct of a study; the publication of research findings (including the suppression of publication); and the treatment of intellectual property interests.

RESPONSES TO CONCERNS ABOUT CONFLICTS OF INTEREST IN RESEARCH

Limits on Conduct of Research by Investigators with Conflicts of Interest

As discussed in Chapter 1, much of the impetus for conflict of interest policies in universities stems from concerns about industry-funded biomedical research and investigators who have financial stakes in the outcomes of their research. In 1995, the U.S. Public Health Services (PHS) issued regulations that require institutions receiving PHS research funding to develop conflict of interest policies that require the disclosure and management of certain financial relationships between researchers and industry (see Appendix B). Chapter 3 noted reviews by NIH and others that questioned the adequacy of policy adoption and the implementation of the PHS regulations by research institutions, which in turn, raised additional concerns about the adequacy of government oversight of institutional compliance.

Because the PHS regulations were not specific on many issues and because some studies indicated shortfalls in their implementation, AAMC issued a report in 2001 with recommendations to help academic medical centers develop sound conflict of interest policies for research involving human subjects (AAMC, 2001).[4] A key policy recommendation called for institutions to establish a "rebuttable presumption" that researchers may not conduct research involving human participants when they have a financial stake in its outcome. This presumption can be rebutted when compelling circumstances justify the researchers' involvement.[5]

A 2003 AAMC survey indicated that only 61 percent of medical schools had adopted the rebuttable presumption in their policies (Ehringhaus and Korn, 2004). In addition, only a minority of the medical schools with such a policy had defined the compelling circumstances that would support an exception.

To further promote the adoption of conflict of interest policies governing research involving human participants, AAMC joined with AAU to issue a second report that offered additional guidance and support for

[4] As noted in Chapter 1, this report generally follows the practice of recent Institute of Medicine reports in referring to research participants rather than to research subjects.

[5] In the words of the AAMC report, the rebuttable presumption means that an "institution will presume, in order to assure that all potentially problematic circumstances are reviewed, that a financially interested individual may not conduct the human subjects research in question" (AAMC, 2001, p. 12). The report goes on to say that the "rule is not intended to be absolute: a financially interested individual may rebut the presumption by demonstrating facts that, in the opinion of the COI [conflict of interest] committee, constitute compelling circumstances . . . [and] would then be allowed to conduct the research under conditions specified by the COI committee and approved by the responsible IRB [institutional review board]" (p. 12).

policy development and implementation (AAMC-AAU, 2008). The report reemphasized the importance of the rebuttable presumption. It also presented informative case studies and a template for analyzing these cases to illustrate how different situations can be evaluated for the existence of a conflict of interest, the risks presented by the conflict, the options for eliminating or managing a conflict, and the compelling circumstances that might justify the participation of an investigator with a conflict of interest in research with human participants. Among the examples of risks cited in the template is the extent to which the reputation of the researcher with a conflict of interest or his or her institution could be damaged, even if a plan for managing the conflict is created and implemented.

Unlike the PHS regulations that cover both clinical and nonclinical research, the 2008 AAMC-AAU recommendations focused on clinical research. One recommendation did, however, call for medical center conflict of interest committees to review investigator conflicts of interests in certain nonclinical studies. Examples include those that can be "reasonably anticipated . . . to progress to research involving human subjects within the coming 12 months" (p. 9).

The committee found much less information and analysis about conflict of interest policies affecting nonclinical biomedical research than about policies affecting clinical research. Universities and medical schools may have different policies for different kinds of research or may apply different criteria to evaluate conflicts of interest in research that does not involve humans (as reported in Chapter 3). One university, however, recently adopted a conflict of interest policy that explicitly states that "[t]o protect against the risks that may accompany relationships with Interested Businesses, it is not ordinarily allowable for an Individual who has a Significant Financial Interest in an Interested Business to Conduct Research involving that Interested Business" (Columbia University, 2009).

Although an immediate risk to research participants does not exist in basic research, the potential for bias in basic research does exist. The result could be the initiation of clinical trials based on flawed basic science. In general, a weighing of risks against expected benefits should allow conflict of interest committees to apply policies while taking into account differences in clinical and nonclinical research, including differences in what constitutes a reasonable justification for researchers to be involved in research in which they have a financial stake.

Terms for Research Contracts

AAMC has not proposed comprehensive formal recommendations on the terms of research contracts with industry, but it has issued two reports with suggestions and recommendations that respond to concerns about

the integrity of clinical trials (Ehringhaus and Korn, 2004, 2006). The first report provides a checklist of topics, including publication rights and intellectual property, to be covered in research contracts. Among other elements, one or both reports call for contracts to explicitly grant researchers free access to study data, to include no restrictions on publication (except for a slight delay for sponsor review and possible filing of a patent application), and to require a good faith and timely effort to publish the results of research in a peer-reviewed journal.

Requirements to Register and Report on Clinical Trials

Congressional, journal editor, and other requirements for the registration of clinical trials are, in part, a response to concerns about conflict of interest in industry-sponsored research and research reporting. The registration of clinical trials and the provision of key details about the trial protocol and the data analysis plan ensure that basic methods for the conduct and analysis of the findings of a study as well as the primary clinical end points to be assessed and reported are specified before the trial begins and before data are analyzed. The substitution of ad hoc or secondary end points for primary end points and other important departures from the protocol can thus be detected in reports of the findings of a trial. Clinical trials registries also allow others to determine whether the results from a trial have not been presented or reported at all. Researchers carrying out critical literature reviews can then contact the investigators to try to obtain unpublished results. After ICMJE stated that clinical trial registration should be considered a prerequisite for the publication of research articles, the numbers of trials registered increased substantially (Zarin et al., 2005).

In 2007, the U.S. Congress expanded the types of clinical trials of drugs, biologics, and devices—and the kinds of information about these trials—that must be registered (P.L. 110-85). To further address the problem of withholding negative findings, it also required the creation of a link from the ClinicalTrials.gov registry to a database of reports of basic results for applicable trials.[6] The reported results are to include basic demographic and baseline information, findings for primary and secondary outcomes, and a point of contact.

[6] In addition, the Pharmaceutical Research and Manufacturers of America has coordinated the creation of a voluntary online resource to provide information to physicians about the results of clinical trials (see http://www.clinicalstudyresults.org/).

Study Methodology, Data Analysis, and Research Reporting

To the extent that the design of clinical trials is standardized and publicized, the implementation of conflict of interest policies is also assisted. Abuses and patterns of abuses can be more readily detected, which may make more evident the need for changes or reforms in the policies. Efforts to improve the design of clinical trials and other types of research stretch back decades and include a range of techniques, including the random assignment of subjects to intervention and control groups and the blinding of investigators and participants to treatment assignment. In addition, NIH has supported programs to train physician investigators to conduct rigorous clinical research. Experts in research methodology, statistics, and evidence-based medicine have developed techniques to limit bias in research and have codified standards and checklists for reporting research findings. These standards and checklists cover various types of studies, including clinical trials (see, e.g., Moher et al. [2001]), evaluations of clinical tests (Bossuyt et al., 2003), epidemiological studies (see, e.g., von Elm et al. [2007], but see also the comments of the editors of *Epidemiology* [Editors, 2007]), and meta-analyses (see, e.g., Moher et al. [1999] and Stroup et al. [2000]).

ICMJE now specifies a format for the reporting of results and refers authors to the CONSORT checklist for the reporting of the findings of randomized clinical trials (see, e.g., Moher et al. [2001], CONSORT Group [2007], and von Elm et al. [2007]) (Table 4-1). Standards for the reporting of methods and results help editors, reviewers, and readers assess the validity of a research paper. Studies suggest that these standards also improve the design and conduct of the research itself (see, e.g., Plint et al. [2005]).

In addition to these standards for the conduct and reporting of the results of clinical trials, the FDA has suggested that it is desirable for the data-monitoring committees for clinical trials to have statistical reports prepared by statisticians who are independent of the trial sponsors and clinical investigators (FDA, 2001). For industry-funded clinical trials "in which the data analysis is conducted only by statisticians employed by a company sponsoring the research," the *Journal of the American Medical Association* requires that a statistical analysis also be conducted by an independent statistician at an academic institution, such as a medical school, academic medical center, or government research institute, that has oversight over the person conducting the analysis and that is independent of the commercial sponsor (Fontanarosa and DeAngelis, 2008, p. 95; see also a review of opinions about this requirement in Rockhold and Snapinn [2007]).

TABLE 4-1 Checklist for Reporting Clinical Trials from CONSORT 2001 Statement

Item	Description
1	How participants were allocated to interventions (e.g., random allocation, randomized, or randomly assigned)
2	Scientific background and explanation of rationale
3	Eligibility criteria for participants and the settings and locations where the data were collected
4	Precise details of the interventions intended for each group and how and when they were actually administered
5	Specific objectives and hypotheses
6	Clearly defined primary and secondary outcome measures and, when applicable, any methods used to enhance the quality of measurements (e.g., multiple observations and training of assessors)
7	How sample size was determined and, when applicable, explanation of any interim analyses and stopping rules
8	Method used to generate the random allocation sequence, including details of any restrictions (e.g., blocking or stratification)
9	Method used to implement the random allocation sequence (e.g., numbered containers or central telephone), clarifying whether the sequence was concealed until interventions were assigned
10	Who generated the allocation sequence, who enrolled the participants, and who assigned the participants to their groups
11	Whether or not participants, those administering the interventions, and those assessing the outcomes were blinded to group assignment; if done, how the success of blinding was evaluated
12	Statistical methods used to compare groups for primary outcome(s); methods for additional analyses, such as subgroup analyses and adjusted analyses
13	Flow of participants through each stage (a diagram is strongly recommended); specifically, for each group, report the numbers of participants randomly assigned, receiving intended treatment, completing the study protocol, and analyzed for the primary outcome; describe protocol deviations from study as planned, together with reasons
14	Dates defining the periods of recruitment and follow-up
15	Baseline demographic and clinical characteristics of each group
16	Number of participants (denominator) in each group included in each analysis and whether the analysis was by intention to treat; state the results in absolute numbers when feasible (e.g., 10/20, not 50%)
17	For each primary and secondary outcome, a summary of results for each group, and the estimated effect size and its precision (e.g., 95% confidence interval)
18	Address multiplicity by reporting any other analyses performed, including subgroup analyses and adjusted analyses, indicating those that were prespecified and those that were exploratory
19	All important adverse events or side effects in each intervention group

TABLE 4-1 Continued

Item	Description
20	Interpretation of the results, taking into account study hypotheses, sources of potential bias or imprecision, and the dangers associated with multiplicity of analyses and outcomes
21	Generalizability (external validity) of the trial findings
22	General interpretation of the results in the context of current evidence

SOURCE: CONSORT Group, 2001 (see also Moher et al. [2001]).

Peer Review and Journal Policies on Disclosure

Peer review is a key step used to detect and reduce bias in publications and improve the quality of research reporting. Effective review depends on independent reviewers who are not biased by their own financial relationships with industry. As described in Chapter 3, journals vary in the extent to which they apply conflict of interest policies to reviewers. Meaningful peer review is also assisted by the previously described standards for the reporting of methods and data in manuscripts.

In response to concerns about the reporting of research results described earlier in this chapter, medical journals have moved toward increasingly specific requirements for disclosure of authors' financial interests (see ICMJE [2008] and WAME [2008] for the statements of two associations of medical journal editors). Still, as described in Chapter 3, journal policies remain variable. The completeness and accuracy of disclosures are continuing issues for medical journals as well as for academic medical centers and other institutions. These concerns have led to action in some states and recommendations for the federal government to establish a policy that requires companies to report payments to physicians, researchers, and institutions, as outlined in the preceding chapter. Chapter 3 includes a committee recommendation supporting such a program.

Issues Involving Research Participants and Students

As described in Chapter 3, AAMC recommended in 2001 and again in 2008 policies that require some form of disclosure of investigator conflicts of interest to research subjects, and many medical schools have adopted those policies. Chapter 3 also reviewed some of the findings from a set of coordinated research projects and activities to investigate the views of research participants and ways of informing them. This research is itself a major response to concerns about practical and ethical issues in managing conflicts of interest in research, for example, balancing the disclosure of

information with the design of an informed consent form and process that does not overwhelm research participants.

AAMC has also recommended the disclosure of investigator conflicts of interests to other members of the research team. It also advised that schools prohibit "agreements with sponsors or financially interested companies that place restrictions on the activities of students or trainees or that bind students or trainees to non-disclosure provisions" (AAMC, 2001, p. 20). In a later statement about the responsibilities of biomedical graduate students and their advisers, AAMC states that advisers should "recognize the possibility of conflicts between the interests of externally funded research programs and those of the graduate student" and should commit that those conflicts will not be allowed to interfere with the student's thesis or dissertation research (AAMC, 2008b, p. 6). The research adviser also agrees to discuss authorship policies and intellectual property policies related to disclosure, patent rights, and publication. In addition, in a series of questions that should be asked when assessing the risks of allowing an investigator with a conflict of interest to conduct research with human participants and the possibility that a conflict can be appropriately managed, the AAMC-AAU report includes questions about whether the "the roles of students, trainees, and junior faculty and staff [are] appropriate and free from exploitation" and whether special protections are needed for "vulnerable members" of the research team (AAMC-AAU, 2008, pp. 25 and 28, respectively). One protection might be to provide such individuals with access to independent senior faculty members for independent review and guidance when questions and concerns arise.

RECOMMENDATIONS

Relationships between industry and research institutions and researchers are common and are often mutually beneficial. They also serve society by generating valuable preventive, diagnostic, and therapeutic products. At the same time, these individual and institutional relationships have risks that could jeopardize the integrity of scientific research and conflict with the ethical conditions for the conduct of research with humans. Analyses indicate that they are associated with decreased openness in sharing data and findings, and cases in which negative findings are not published in a timely fashion or at all raise concerns. Some studies also suggest that meta-analyses sponsored by a single company tend to present conclusions favorable to industry sponsors even when the actual findings of the analyses are not favorable. Moreover, when investigators themselves have a financial stake in the outcomes of their research, it creates conflicts of interest, which may lead to bias and the erosion of confidence in the research enterprise.

Chapter 2 discussed why conflicts of interest matter even if they do not

actually lead to undue influence or bias in a particular case. Correlations or associations in studies such as those reported here are enough to support concerns over potential conflicts of interest. The purpose of conflict of interest policies is preventive: the policies are intended to remove or reduce relationships that create a risk of undue influence or erosion of confidence in the research enterprise.

As described in this chapter and in Chapter 3, research institutions vary in their conflict of interest policies, including the extent to which they have adopted and implemented PHS conflict of interest regulations and policies recommended by AAMC and AAU. Government and press investigations and payment data reported by companies have revealed failures of individual researchers to fully and accurately disclose their financial relationships with industry, as required by institutional or government policies.

The preceding section of this chapter provided an overview of recommendations for action that should be taken by research institutions, research sponsors, investigators, and medical journals to protect the integrity of biomedical research, safeguard research participants, and preserve public trust. The recommendation below focuses on one specific concern: the conduct of research with human participants by investigators with a financial interest in the outcome of that research. The discussion of the recommendation is followed by a review of standards for nonclinical research and a suggestion that NIH take a lead role in further examination of the involvement of conflicted investigators in this kind of research.

Clinical Research

It is critical that the public trust that research institutions are protecting the integrity of the medical research on which clinical practice and education depend. Such protection is especially important in clinical research because bias in the design, conduct, or reporting of the findings of such research may expose human participants to risks without the prospect of gaining valid, generalizable knowledge and may ultimately expose much larger numbers of patients to ineffective or unsafe clinical care.

Recommendation 4.1 calls for research institutions to allow researchers with a conflict of interest to conduct research involving human participants only when a researcher's participation is truly essential and is also managed to limit risk. This recommendation is similar to the AAMC "rebuttable presumption" described earlier in this chapter.

RECOMMENDATION 4.1 Academic medical centers and other research institutions should establish a policy that individuals generally may not conduct research with human participants if they have a significant financial interest in an existing or potential product or a

company that could be affected by the outcome of the research. Exceptions to the policy should be made public and should be permitted only if the conflict of interest committee (a) determines that an individual's participation is essential for the conduct of the research and (b) establishes an effective mechanism for managing the conflict and protecting the integrity of the research.

This recommendation covers principal investigators and others who share substantial responsibility for the design, conduct, or reporting of the findings of clinical studies. Relevant financial interests often involve stock or other ownership in a company making a product that could be affected by the results of a study, including not only a product under study but also a product that is an alternative to the intervention under study. (Although AAMC recommended no minimum threshold for the initial disclosure of financial interests, it suggested that "significant interest" should generally be defined as a financial interest of $10,000 or more.)

In exceptional cases, a clinical investigator may be judged to be essential if his or her participation is determined—after careful assessment—to be necessary for the safety, reliability, or validity of the research, circumstances that AAMC described as compelling. Often cited as examples are situations in which inventors of a medical device or investigators responsible for certain kinds of breakthrough scientific discoveries are crucial to research, especially early-phase studies, because of their "insights, knowledge, perseverance, laboratory resources" or access to "special patient populations" (AAMC-AAU, 2008, p. 6; see also Witkin [1997] and Citron [2008]).

A specific example of a compelling situation might involve the participation in a pilot study of the inventor of an implanted medical device that requires a complex, new surgical procedure that has not been mastered by others. The reasons for allowing a researcher with a conflict of interest to participate in a pilot or early-phase study or other investigation in a particular situation should be persuasive to others who are presented with the facts of the case. In most cases of a conflict of interest, no compelling argument that the investigator's participation is essential can be made. Even if the investigator's participation is essential, the elimination of the conflict of interest (e.g., through the sale of stock) is the preferred step. If an exception is granted, it should be made public.

If an exception is made for an investigator with a conflict of interest, the next step is for the conflict of interest committee to establish a strategy for managing the conflict and a plan for monitoring the strategy's implementation during the course of the research. For instance, the plan might specify that the researcher with the conflict of interest not serve as the principal investigator. It might also restrict the researcher recruiting

subjects; obtaining informed consent; assessing the clinical end points; analyzing data; or writing the results, conclusions, and abstracts for publications reporting the findings of the study. The plan might, however, allow the researcher to participate in aspects of study design, fund raising, and manuscript review.

Nonclinical Research

Most of the discussion of conflicts of interest in research has focused on clinical research. This emphasis reflects concerns that research participants might be harmed or that bias might contribute to the making of incorrect decisions about approving new drugs and devices or changing clinical practice. Because conflicts of interest in various kinds of nonclinical research have been little investigated, the committee found it difficult to evaluate arguments about the extent and the consequences (or the lack of consequences) of investigator and institutional conflicts of interest in this sphere of research. It thus did not make a formal recommendation about conflicts of interest in nonclinical research. The committee did, however, hear testimony that new models of academia-industry collaboration are needed to promote basic scientific discoveries and the development of new therapies while also addressing concerns about conflicts of interest (Moses, 2008; see also Moses and Martin [2001]).

No matter the type or stage of research, certain fundamentals still apply. All researchers should be subject to an institution's disclosure policies, as described in Chapter 3, and the institution's conflict of interest committee or its equivalent should be notified when investigators have financial stakes in the outcomes of their research. Similarly, following the conceptual framework presented in Chapter 2, once a financial relationship or interest has been disclosed, it should be evaluated for determination of the likelihood that it will have an undue influence that will lead to bias or a loss of trust. If a risk is judged to exist, a conflict of interest committee might conclude that the implementation of safeguards is necessary. Such safeguards could consist of a management plan that includes the involvement of a researcher without a conflict of interest in certain aspects of the research and disclosure of the conflict to coinvestigators and in presentations and publications.

Additional studies on the extent of financial relationships in nonclinical research and their consequences, as well as the consequences of conflict of interest policies, are needed to establish a sounder base of evidence for future policies. Given its extensive and direct relationships with basic scientists, NIH could play a central role in gathering such evidence. As discussed in Chapter 9, NIH could fund research on conflicts of interest in nonclinical scientific research. Furthermore, NIH could convene working groups and

public meetings to promote a fuller understanding—empirical, conceptual, and practical—of conflicts of interest in nonclinical research and propose responses. Such meetings might identify good practices in developing academia-industry relationships in nonclinical research and suggest how such relationships might be developed in ways that promote constructive collaboration while appropriately addressing concerns about conflicts of interest. The development of illustrative case studies might help institutions better understand and manage conflicts of interest in nonclinical research.

Other Relevant Recommendations in This Report

The adoption of the recommendations made elsewhere in this report would also affect researchers, research institutions, and companies. These recommendations call for standardization of the procedures used to disclose conflicts of interest to harmonize the requirements of different institutions and reduce the disclosure burdens on individuals (Recommendation 3.3), implementation of methods for the easier verification of certain financial disclosures (Recommendation 3.4), limitations on certain relationships with industry (e.g., acceptance of gifts and participation in promotional activities) for academic medical center personnel (Recommendation 5.1), and promotion of reforms in industry policies on consulting and research grants (Recommendation 6.2).

Chapter 8 includes a recommendation that responsibility for the oversight of institutional conflicts of interest be lodged in the governing boards of institutions (Recommendation 8.1). Many conflicts of interest at the institutional level involve research or proposed research in which a university or medical school has a financial stake related to its interests in patents or start-up companies.

In addition, the committee recommends that other public and private organizations create incentives to support the adoption of the recommendations made in this report (Recommendation 9.1). As one example, NIH could expand its recent efforts to provide more guidance and oversight to grantee institutions covered by the PHS regulations, issue regulations directing grantees to adopt institutional conflict of interest policies (Recommendation 8.2), and take a lead role in the development of a research agenda on conflict of interest (Recommendation 9.2). NIH could also consider requiring investigators funded by NIH awards to be trained on conflict of interest principles and policies. (NIH has a new training module on conflict of interest that could be tailored for investigators.) Other public agencies that support academic biomedical research, for example, the U.S. Department of Defense, could also provide guidance compatible with that presented in this report.

Taken together, the changes recommended here should not burden socially valuable collaborations between academic researchers and industry. Rather, they should help justify and maintain public trust in their integrity.

5

Conflicts of Interest in Medical Education

Medical education prepares physicians for a lifetime of professional work. Education that is objective and that teaches students how to critically evaluate the evidence prepares physicians to keep current with scientific advances throughout their professional lives.

This chapter is organized around the concept of the learning environment, which shapes and reinforces the professional attitudes and behavior of physicians throughout the continuum of learning that begins in medical school and extends through residency training and to lifelong learning. Learning environments in medicine are diverse. They include conference rooms and lecture halls, patient care locales (such as inpatient service and outpatient practice locations), laboratories, and the Internet. Some continuing education programs take place at restaurants or resorts.

If the learning environment provides the stage for education, the curriculum provides the script. Reviews of undergraduate and graduate medical education often emphasize the "formal curriculum" (i.e., required courses and explicit educational objectives).[1] That formal curriculum aims to help students develop the core competencies that are defined by accreditation agencies. Each educational activity has learning objectives, and the totality of educational sessions must address all the core competencies.

The learning environment also includes two other elements: the informal curriculum (i.e., ad hoc interactions among teachers and students) and

[1] The committee follows the convention in medical education of referring to the years of medical school as "undergraduate medical education" and the post-M.D. years of residency and fellowship as "graduate medical education." Unless otherwise described (e.g., research fellows), fellows are physicians in subspecialty training programs. This report refers to "residents" and "fellows" rather than "trainees" (a description commonly used by medical educators).

the hidden curriculum (i.e., institutional practices and culture) (see, e.g., Hafferty [1998], Ratanawongsa et al. [2005], Cottingham et al. [2008], and Haidet [2008]). Ideally, these two elements convey messages that are consistent with the formal curriculum, but in practice they may not. For example, the formal curriculum might include course work on medical ethics, research methodology, and appropriate relationships with industry. Concurrently, the informal and hidden curricula might be characterized by disparaging faculty comments on their institution's conflict of interest policies and the failure of institutions to adopt and implement sound policies.

Unfortunately, some aspects of each curriculum may contribute to undesirable attitudes or practices. The Association of American Medical Colleges (AAMC) observed in a 2008 report that the conflicts created by a range of common interactions with industry can "[f]or medicine generally, and for academic medicine in particular . . . have a corrosive effect on three core principles of medical professionalism: autonomy, objectivity, and altruism" (AAMC, 2008c, p. 4). Members of the U.S. Congress have also expressed concern about commercial relationships in medical education, primarily continuing medical education (see, e.g., Finance Committee, U.S. Senate [2007]). In contrast to the requirements for recipients of U.S. Public Health Service research awards, the federal government does not require the recipients of direct or indirect funds for medical education to establish and administer conflict of interest policies.

This chapter next provides a brief background on the current context of medical education. It then examines the literature on conflict of interest issues and responses in the learning environments of undergraduate, graduate, and continuing medical education. The discussion covers access to educational environments by sales representatives of medical product companies (e.g., drug detailing, which is a visit to a doctor by a sales representative for a pharmaceutical company), the provision of drug samples and other gifts to faculty and students, and industry-sponsored scholarships and fellowships. A separate section considers a concern that cuts across all phases of education: intellectual independence in presentations and publications and the risks associated with speakers bureaus and ghostwritten publications. (Chapter 4 discussed concerns about how researcher conflicts of interest might affect their advice or supervision involving the research of medical students, residents, fellows, and junior faculty.)

The committee concluded that, in general, industry financial relationships do not benefit the educational missions of medical institutions in ways that offset the risks created. The chapter thus ends with recommendations that are intended to protect the integrity and limit the potential for undue industry influence in medical education. As explained in Chapter 1, the committee focused on conflicts of interest involving physicians and biomedical researchers; but much of the core rationale for the recommendations

may be relevant to nursing, pharmacy, dentistry, and other professions, even though some of the specifics might differ. Chapter 6 considers many of the same issues in the context of physicians in practice outside academic settings.

BACKGROUND AND CONTEXT

Scale and Oversight of Medical Education

American medical education evolved during the 19th and early 20th centuries from pure apprenticeships to proprietary medical schools of variable quality to a reformed and formal educational system that stresses both science and professionalism. During the middle decades of the 20th century, an increasingly elaborate structure of graduate (post-M.D.) medical education emerged, characterized by multiyear residencies in medical specialties beyond the traditional internship year. The latter half of the century saw the growth of requirements by state licensing boards and specialty certification boards for demonstrated participation in accredited continuing education activities (Caplan, 1996).

Today, the scale of American medical education is impressive. The United States has

- 130 accredited medical schools (AAMC, 2008d),[2] approximately 400 major teaching hospitals (Salsberg, 2008), more than 100,000 faculty members (Salsberg, 2008), and approximately 75,000 medical students (AAMC, 2008e);
- 8,355 accredited residency programs for 126 specialties and subspecialties (2006–2007) and more than 107,000 active full-time and part-time residents (2005–2006) (ACGME, 2007b); and
- 740 national providers of accredited continuing medical education (and 1,600 accredited state providers)[3] that reported more than 7 million physician participants in their programs (ACCME, 2008a, 2009), a number that includes multiple registrations among the nation's more than 800,000 active physicians (a count that includes medical residents) (Salsberg, 2008).

[2] The count includes four schools granted preliminary accreditation in 2008. It does not include accredited Canadian schools or the 20 accredited U.S. schools of osteopathic medicine.

[3] These providers are accredited by state medical societies under the rules of the Accreditation Council on Continuing Medical Education.

The Liaison Commission on Medical Education (LCME) is the oversight agency that is responsible for the accreditation of the nation's medical schools. Its members are appointed by AAMC and the American Medical Association (AMA). The Accreditation Council for Graduate Medical Education (ACGME) accredits residency training programs in the United States. The sponsoring institution for a residency program may be a hospital, medical school, university, or group of hospitals (ACGME, 2008). Accreditation bodies define the core competencies for students, residents, and fellows and ensure that the formal curriculum covers all essential aspects of medical education. ACGME board members are appointed by AAMC, AMA, the American Board of Medical Specialties, the American Hospital Association (AHA), and the Council of Medical Specialty Societies (CMSS). Accredited continuing medical education providers are accredited by the Accreditation Council for Continuing Medical Education (ACCME). Its member organizations are AHA, AMA, AAMC, CMSS, the Association for Hospital Medical Education, and the Federation of State Medical Boards. State medical societies may also accredit providers within a state.[4] In addition, AMA, the American Academy of Family Physicians, and certain other groups set standards and certify credits for specific courses that physicians can take (from accredited providers) to meet state licensure board and other requirements for accredited continuing medical education (see, e.g., AMA [2006, 2008b]).[5] Accredited providers usually issue certificates to document that a physician has completed a certified course. Consistent with common usage, this report uses the phrase accredited continuing medical education to refer to education that is (1) presented by accredited providers and (2) certified for course credits.

Changing Environment and Fiscal Challenges

Academic medical centers dominate the provision of undergraduate and graduate medical education. The institutions consist of two related enterprises: a medical school that trains physicians and conducts research and a system that provides health care services. The latter system may include teaching hospitals, satellite clinics, and physician office practices. Academic health centers include other health professions schools, such as a school of dentistry, nursing, or pharmacy (Wartman, 2007).

[4] As described by ACCME, "ACCME has two major functions: the accreditation of providers whose CME [continuing medical education] activities attract a national audience and the recognition of state or territorial medical societies to accredit providers whose audiences for its CME activities are primarily from that state/territory and contiguous states/territories" (ACCME, 2005).

[5] AMA also authorizes credits for other activities, such as publishing an article in a peer-reviewed journal or achieving and maintaining specialty board certification.

In recent years, academic medical centers have struggled financially because of low levels of payment for poor and uninsured patients, reductions in the Medicare indirect medical education adjustment for hospital payment rates, and lower profit margins for the provision of hospital services to Medicare patients. (In the late 1990s, medical schools also faced declining admissions, but admissions increased from 2003 to 2007 [AAMC, 2008a].) At the same time, teaching hospitals have faced rising costs because of the incorporation of new medical informatics systems and expensive medical technologies and restrictions on the numbers of hours that residents may work. The Medicare Policy Advisory Commission has characterized 53 percent of major teaching hospitals as being under high financial pressure—compared to 28 percent of hospitals overall (MedPAC, 2009). Given these circumstances, financial support from industry may seem attractive.

Physicians in training also face financial challenges. In 2006, the median levels of debt of medical students graduating from public and private medical schools were $120,000 and $160,000, respectively (Jolly, 2007). Medical school graduates can expect to pay approximately 9 to 12 percent of their after-tax income after graduation for educational debt service (Jolly, 2007). This level of indebtedness and the delayed gratification of a profession that requires years of training before independent practice is permitted can contribute to a sense of entitlement, which, in turn, may position medical students, residents, and fellows to be strongly influenced by gifts and attention from representatives of pharmaceutical and medical device companies (see, e.g., Levine [2008]). Sierles and colleagues (2005) found that 80 percent of the medical students that they surveyed believed that they were entitled to gifts. In addition, as discussed in Chapter 6, once they are in practice, limits on reimbursements for physician services make debt repayment more of a burden than in the past and may make gifts and other financial relationships with industry more appealing.

Industry Funding of Medical Education

During most of the 20th century, medical product companies were not major participants in medical education. The exception was sales representatives, who provided information to residents and faculty as well as to nonacademic physicians. In the latter decades of the century, however, medical product companies became increasingly involved in sponsoring continuing medical education, including grand rounds and other academic-based programs. In a 2008 report on industry funding of medical education, a task force of AAMC observed generally that

> Over recent decades, medical schools and teaching hospitals have become increasingly dependent on industry support of their core educational mis-

> sions. This reliance raises concerns because such support, including gifts, can influence the objectivity and integrity of academic teaching, learning, and practice, thereby calling into question the commitment of academia and industry together to promote the public's interest by fostering the most cost-effective, evidence-based medical care possible. (AAMC, 2008c, p. iii)

The committee found no data on the amount or proportion of undergraduate or graduate medical education supported by industry. It also found little systematic information on specific categories of financial support, for example, grants for residencies or fellowships, direct or indirect financial support for grand rounds, or donations for buildings or other capital items. The most extensive information on academic institutions' ties with industry comes from a 2006 survey of department chairs at medical schools and the 15 largest independent teaching hospitals (67 percent response rate). The responses indicated that 65 percent of clinical departments received industry support for continuing medical education, 37 percent received industry support for residency or fellowship training, 17 percent received industry support for research equipment, and 19 percent received unrestricted funds from industry for department operations (Campbell et al., 2007b). The committee did not categorize industry payments for meals, gifts, and visits by sales representatives as support for medical education because these activities do not fit the learning objectives in the formal curriculum.

Information on industry funding for accredited continuing medical education comes from yearly surveys by ACCME. Figure 5-1 shows that commercial sources (excluding advertising and exhibits at programs organized by accredited providers) provide a substantially larger share of income for education providers today than they did in 1998. By 2003, about half of all funding for accredited continuing medical education programs came from commercial sources. The fees paid by program attendees once provided the majority of provider income, but today industry-supported programs are often provided free or at reduced cost to physicians (Steinbrook, 2008a).

LEARNING ENVIRONMENTS IN MEDICAL SCHOOLS AND RESIDENCY PROGRAMS

The ultimate mission of medical education is to prepare physicians to provide effective, safe, high-quality, efficient, timely, affordable, and patient-centered care to patients. In revising the standards that provide the framework for essential aspects of medical education, both LCME and ACGME have recently emphasized how the learning environment can affect the development of core professional values and core competencies, includ-

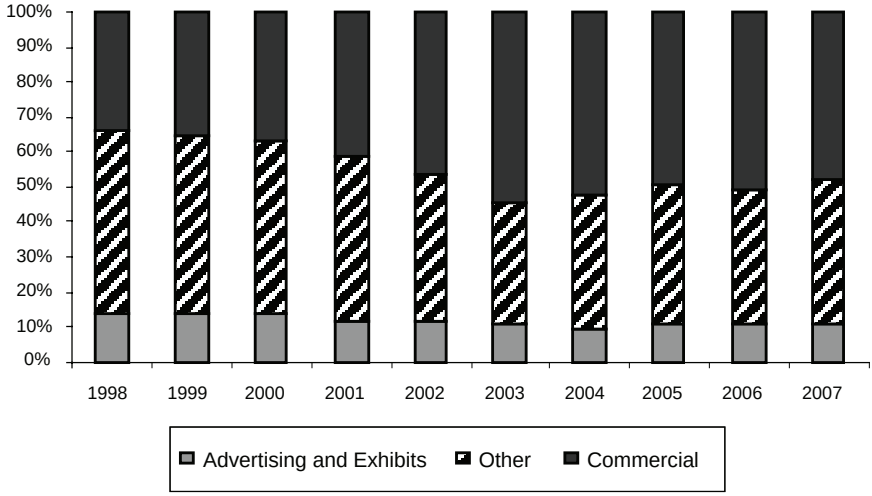

FIGURE 5-1 Sources of income reported by respondents (accredited providers of continuing medical education) to ACCME annual survey, 1998 to 2007. SOURCE: Compiled from ACCME, 2008a.

ing how to critically review the evidence and to commit to lifelong learning about scientific advances.

Both LCME and ACGME recognize the power of the local learning environment to shape the knowledge, skills, behaviors, and attitudes of the next generation of physicians. To achieve accreditation, institutions providing undergraduate or graduate medical education must have curricula and resources that, among other requirements, (1) promote the development of appropriate professional attributes; (2) help learners at all levels think critically and appraise the evidence base for research reports, practice guidelines, and marketing materials; and (3) provide appropriate role models and mentoring. In addition, a standard on the creation of the appropriate learning environment must be implemented (LCME Standard MS-31-A). Recently, ACGME has required institutions to have a statement or institutional policy that addresses interactions between vendor representatives or corporations and residents and their programs (Requirement III. B.13 [ACGME, 2007a]).

The Learning Environment in Undergraduate and Graduate Medical Education as a Target of Industry Influence

Scope of Relationships Between Industry and Students, Medical Schools, and Teaching Hospitals

Interactions between medical students and industry are common. Table 5-1 summarizes the results from a survey of third-year medical students at eight major medical schools. Almost all students had received an industry-provided lunch or other gift. More than one-third had attended a social event hosted by a drug company.

Information from two surveys of residency directors similarly documents frequent interactions with pharmaceutical companies. For example, a 2002 survey of emergency medicine residency program directors found that approximately 40 percent allowed industry to fund social activities, and a similar percentage allowed pharmaceutical representatives to teach residents (Keim et al., 2004). Twenty-nine percent said that industry travel support could be made contingent on residents attending an industry event. Only 50 percent said that they always or very frequently followed ACGME recommendations for industry funding of core lectures, and 10 percent said that they always or very frequently allowed pharmaceutical representatives unrestricted access to residents. In a 2002 survey of psychiatric residency program directors, 88 percent reported that they allowed industry to provide lunches for their residents, and among this group, the mean was about five lunches per week (Varley et al., 2005). Approximately a third of the programs solicited travel funds from industry (31 percent) or allowed residents to seek such funding from industry on their own (34 percent).

Value of Relationships

Some interactions with industry can have educational value, for example, when an industry scientist participates in a seminar on drug development strategies or when a device company representative provides supervised training on a complex and innovative medical device that has recently been approved for marketing. Other examples may include unrestricted grants to academic medical centers that support student or resident research stipends or participation in scientific conferences. On a much larger scale, universities have benefited from company gifts for buildings, research programs, and auditoriums.

Pharmaceutical companies argue that their representatives provide information on new drugs. Yet, medical students, residents, and fellows have ready access to the latest scientific information through faculty members, information technologies that allow them to search the medical literature,

TABLE 5-1 Third-Year Medical Students' Interactions with Drug Companies

Type of Event	No. of Students. (N = 826)	No. (%) of Students Who Received a Gift or Participated in at Least One Event	Exposure Frequency per Month[a]	
			Mean (SD)	Range
A lunch provided by a drug company	793	768 (96.8)	1.08 (0.76)	0–4.2
A small, noneducational gift (e.g., pen or coffee mug)	801	754 (94.1)	0.87 (0.69)	0–3.5
A journal reprint or a glossy brochure from a pharmaceutical representative	800	716 (89.5)	0.53 (0.52)	0–3.5
A snack (e.g., donut, candy, coffee) provided by a pharmaceutical representative	800	713 (89.1)	0.75 (0.72)	0–8.5
A grand rounds sponsored by a drug company	798	690 (86.5)	0.54 (0.57)	0–2.4
A dinner provided by a drug company	801	405 (50.6)	0.13 (0.21)	0–2.4
A drug sample from a pharmaceutical representative	799	435 (54.4)	0.10 (0.20)	0–2.1
Another social event (e.g., party) sponsored by a drug company	799	272 (34.0)	0.06 (0.11)	0–0.8
A book donated by a drug company[b]	826	421 (51.0)		
Attendance at a workshop sponsored by a drug company[b]	826	214 (25.9)		
Registration fee for a conference paid for by a drug company[b]	826	37 (4.5)		
Participation in a market survey sponsored by a drug company[b]	826	29 (3.5)		
Participation in a research project sponsored by a drug company[b]	826	22 (2.7)		
Travel expenses for a conference paid for by a drug company[b]	826	15 (1.8)		
Nominated for an award sponsored by a drug company[b]	826	5 (0.6)		
Obtained a fellowship sponsored by a drug company[b]	826	4 (0.5)		

[a]For each student, an exposure index was calculated as the sum of the monthly frequencies for the first eight items.
[b]Monthly frequency data were not requested.

and open-access sources of evidence-based literature reviews and summaries. The committee recognizes that some medical students and residents who have become accustomed to interactions with representatives may value the meals that they receive as a respite and may view the gifts that they bring as either inconsequential or as an appropriate reward for their demanding schedules and economic sacrifices.

The discussion below focuses on several different types of academic-industry relationships and the literature about their consequences. Each section includes a discussion of private- and public-sector responses to concerns about the extent and consequences of these relationships. In addition to consulting reports by AAMC and other groups, the committee examined the policies of a number of medical schools. It found many of these policies at or available through links from the websites of the American Medical Student Association (AMSA) and the Institute on Medicine as a Profession (IMAP). The AMSA website also includes the organization's scorecard, which presents school-by-school ratings of various policy elements (e.g., the policy on the acceptance of gifts) and which has received considerable attention from the media.[6]

The committee notes that the recommendations in the 2008 AAMC report on medical education apply off campus as well as on campus. The report calls for academic medical centers to "communicate to off-site training facilities their expectation that the off-site venues will adhere to the standards of the academic center regarding interactions with industry" (AAMC, 2008c, p. 10).

Site Access by Drug and Device Company Representatives

Issues and Evidence

Drug detailing, that is, a visit to a doctor by a sales representative for a pharmaceutical company, is a common way that companies promote their products and establish relationships with physicians in academic and community settings. In 2004, an estimated 36 percent of the $57.5 billion that pharmaceutical companies spent on product promotion went for detailing (Gagnon and Lexchin, 2008).

Medical device companies also employ sales representatives to promote their products to physicians and hospitals, although the responsibilities of

[6] The AMSA ratings, the methodology, and other information can be found at http://amsascorecard.org/. The IMAP information can be found at http://www.imapny.org/coi_database/. Both groups use information and policies received in response to a survey conducted under the auspices of the Prescription Project with funding from the Pew Charitable Trust. Some schools did not respond initially, and others refused to supply their policies.

some of these representatives may be more complex. They may provide training, equipment calibration, and additional services or advice related to implants and other sophisticated technologies used in the operating room and elsewhere (see, e.g., ECRI Institute [2007]). In one instance, the Food and Drug Administration (FDA) has required physicians to be trained by company representatives as a condition for the approval of a device (see, e.g., FDA [2004b] and Dawson [2006]).

The committee did not locate any information about how drug or device detailing activity differs between academic and nonacademic settings or how specific tactics of detailing and their effects may vary by setting or type of physician (e.g., resident versus faculty member versus community physician). Interactions with drug company representatives are common in academic settings. Medical students average about one interaction with drug company representatives a week, and 80 to 100 percent of students report interactions (see, e.g., Bellin et al. [2004], Sierles et al. [2005], and Fitz et al. [2007]). As described by one faculty member,

> [d]rug company representatives are a major presence. They sponsor Journal Club (where trainees learn to review new data and research), they pay for many of our weekly speakers and regularly offer free dinners for the residents and faculty. They enjoy free access to our mailboxes and regularly detail our trainees in their offices, hallways and in our little kitchen. (Shapiro, 2004, p. F5)

Medical students and residents reported that they received insufficient training in interacting with drug representatives. Studies also indicate that students and residents believe that their own prescribing behavior is not affected by drug company gifts, although they believe that the prescribing behavior of their colleagues is (Sierles et al., 2005; Zipkin and Steinman, 2005). Limited evidence suggests that educational interventions "show some promise" in affecting the attitudes and behaviors related to relationships with industry (Carroll et al., 2007).

Overall, research suggests that drug company representatives may influence prescribing patterns and requests for additions to hospital formularies. The effects appear to be modest but consistent across various kinds of research and disciplines. One review concluded that the "pharmaceutical industry has a significant presence during residency training, has gained the overall acceptance of trainees, and appears to influence prescribing behavior" (Zipkin and Steinman, 2005, p. 777). Another review (which was not limited to educational settings) concluded that detailing "affects physician prescription behavior in a positive [i.e., the more detailing that there is, the more of an effect that it has] and significant manner" (Manchanda and Honka, 2005, p. 787).

Taken together with the information reviewed below on the role of drug samples and gifts (which typically accompany sales visits), the literature suggests that academic medicine and the public have reason to be concerned about the easy access of sales representatives to medical students, residents, and faculty. In addition, the committee could find no evidence that the exposure of students and residents to drug and device sales representatives—without additional training and supervision—contributes to the achievement of learning objectives or the development of core competencies, for example, increasing an individual's ability to critically evaluate presentations or promoting adherence to evidence-based clinical practice guidelines.

Responses

AAMC has recommended tight limits on site access by sales representatives from medical product companies, particularly uninvited and unscheduled visits and unsupervised access to individual students and residents (see Box 5-1) (see, e.g., AMSA [2008a] and AAMC [2008c]). The recommended rules for device representatives are somewhat less stringent than those for drug representatives and allow limited exceptions for training on the use of complex new devices and the other activities mentioned above. A number of medical schools and teaching hospitals have adopted policies consistent with the AAMC recommendations.

A quality assurance and risk management document prepared by the ECRI Institute (2007) recommends several additional safety and administrative provisions for device representatives who are allowed access to the operating room.[7] The recommendations include training requirements for device representatives as well as procedures to ensure patient safety, privacy, and informed consent and to prevent kickbacks (ECRI Institute, 2007). In addition, the ECRI Institute document suggests that medical schools have not provided adequate training in the use of devices. It emphasizes that hospitals and physicians are responsible for seeing that personnel have the appropriate training on the use of the devices that they regularly use, so that reliance on device representatives is limited and appropriately supervised.

[7] ECRI Institute is a technology assessment organization that has a long history of providing advice to health care institutions and government on medical device safety. It is one of the Evidence-Based Practice Centers designated by the Agency for Healthcare Research and Quality and is a Collaborating Center of the World Health Organization.

AAMC Recommendations on Site Access by Sales Representatives

Site Access by Pharmaceutical Representatives

- To protect patients, patient care areas, and work schedules, access by pharmaceutical representatives to individual physicians should be restricted to non-patient care areas and nonpublic areas and should take place only by appointment or invitation of the physician.
- Involvement of students and trainees in such individual meetings should occur only for educational purposes and only under the supervision of a faculty member.
- Academic medical centers should develop mechanisms whereby industry representatives who wish to provide educational information on their products may do so by invitation in faculty-supervised structured group settings that provide the opportunity for interaction and critical evaluation. Highly trained industry representatives with M.D., Ph.D., or Pharm.D. degrees would be best suited for transmitting such scientific information in these settings.

Site Access by Device Manufacturer Representatives

- Access by device manufacturer representatives to patient care areas should be permitted by academic medical centers only when the representatives are appropriately credentialed by the center and should take place only by appointment or invitation of the physician.
- Representatives should not be allowed to be present during any patient care interaction unless there has been prior disclosure to and consent by the patient, and then only to provide in-service training or assistance on devices and equipment.
- Student interaction with representatives should occur only for educational purposes under faculty supervision.

Drug Samples

Issues

Physicians and patients often value drug samples provided as gifts because they allow physicians to send a patient home with a medication that can be evaluated for its short-term effects and side effects without requiring the patient to fill and pay for a full prescription. For low-income patients, many of whom are treated at academic medical centers and teaching hospitals, samples can provide access to needed medications (Daugherty, 2005).

Some research has, however, suggested that poor or uninsured patients are somewhat less likely than higher-income or insured patients to receive a drug sample (Cutrona et al., 2008). Drug samples may also be used by physicians themselves or their families. In a 1997 survey of residents, 32 percent of all medications used by residents were obtained from drug sample cabinets or directly from drug representatives (Christie et al., 1998). As discussed in Chapter 6, some professional societies approve such use.

Other research points to risks associated with physician acceptance of drug samples. In academic medical centers, drug samples may be associated with the prescription of new brand name drugs in situations in which the sample drugs are different from the physician's preferred drug or are not recommended by evidence-based practice guidelines or in situations in which less expensive drugs or generic equivalents are available for the same indication. One study of a sample of university-based physicians' responses to several clinical scenarios found that from 17 to 82 percent of the physicians would dispense a drug sample, and, in two of three scenarios, a great majority would do so instead of using their usually preferred drug—largely on the grounds that use of the sample would avoid costs to the patient (Chew et al., 2000). Residents were more likely than attending physicians to report that they used drug samples. In a second study, which involved residents in an inner-city clinic, half were randomized to forgo the use of available free drug samples. They were more likely than the control group to choose unadvertised drugs and were more likely to use over-the-counter drugs. The authors concluded that access to drug samples influences residents' prescribing decisions (Adair and Holmgren, 2005). A third study found that physicians who prescribed angiotensin-converting enzyme inhibitors or calcium channel blockers (a departure from the recommendations of the Joint National Commission on High Blood Pressure Treatment) were more likely than other physicians to report that they provided patients with samples of antihypertension medications (Ubel et al., 2003). This relationship persisted even after physician and practice variables were taken into account.

Responses

Concerns about the possible negative effects of drug samples have led some academic health centers to restrict or ban their provision. For example, some medical schools require drug samples to be received and distributed by a medical center pharmacy and prohibit their direct provision to individual physicians (see, e.g., University of Massachusetts [2008]). Other policies may allow donation of products only for purposes of evaluation or education and not to support "patient care purposes on an ongoing basis" (University of California, 2008, p. 4). When the University of Michigan

Health System (2007) prohibited the distribution of drug samples in patient care and non-patient care areas, it provided committee-approved vouchers for starter medications for clinic patients and for limited exceptions if a clinic director believed that a sample of a specific drug was clinically necessary. The most common provision among the policies reviewed by the committee was a prohibition on the personal use of samples by physicians or their family members.

AAMC (2008c) recommends that samples—if their distribution is by the institutions—should be centrally managed, when feasible (e.g., when timely access to the medications is possible). It warns that the "acceptance and use of drug samples transmits the message to students and trainees that information about samples received from industry sales personnel is sufficient without independent critical evaluation" (p. 16). The recommendation does not mention the personal use of samples by physicians or their family members or staff.

In a March 2009 report, the Medicare Payment Advisory Commission recommends that the U.S. Congress require manufacturers and distributors of drugs to report their distribution of drug samples. It also recommends that the secretary of the U.S. Department of Health and Human Services make the information available for analysis through data use agreements.

Gifts from Medical Product Companies

Issues

As noted earlier in this chapter, surveys indicate that almost every medical student has received a meal and a small noneducational gift from a drug company and that other interactions are common as well (see, e.g., Sigworth et al. [2001], Bellin et al. [2004], Sierles et al. [2005], and Fitz et al. [2007]). In one study, residents were asked to empty their pockets of pens, penlights, calipers, and other items (Sigworth et al., 2001). Ninety-seven percent of the residents had at least one item marked by a pharmaceutical insignia, and about half of the items carried by residents were so branded. More than 90 percent of the residents said that they thought that interactions with drug company representatives influenced their prescribing.

The committee found no studies documenting an educational benefit of these kinds of gifts from industry. Although medical students or residents may find the gift of an expensive textbook welcome, nothing similar to the benefits of academic-industry collaboration in biomedical research has been argued for gifts from industry in medical education.

In contrast, studies of medical personnel combined with social science research provide reasons for concern about the risks of industry relationships and gifts, even small gifts. The paper by Jason Dana in Appendix D

reviews this literature. It suggests that even small gifts can be influential. Furthermore, because influence may operate at an unconscious level, it can distort the choices of people who believe that they are objectively making decisions. Disclosure of interests and education about bias may be useful, but they cannot be relied upon to overcome the potential for undue influence and bias associated with conflicts of interest. A number of studies suggest that medical residents, faculty, and other physicians tend to think that they themselves are less likely than others to be influenced by gifts or other interactions (see, e.g., McKinney et al. **[1990], Steinman et al.** [2001], Halperin et al. [2004], Zipkin and Steinman [2005], and Morgan et al. [2006]).

Few studies have specifically investigated the effects of industry relationships on teaching. One study compared the attitudes of internal medicine residents and faculty about the impact of gifts or income from industry on teaching within and outside the institution (Watson et al., 2005). In general, students were more likely than faculty to perceive industry influence in association with gifts or income. Both students and faculty perceived visiting attending faculty as more susceptible to such influence than regular faculty, and both perceived off-site teaching as more subject to influence than on-site activities. For example, residents were more likely than faculty to believe that gifts or income from industry influences how attending physicians teach on rounds (47 versus 34 percent), during in-hospital lectures and journal clubs (58 versus 30 percent), and during out-of-hospital dinner lectures and journal clubs (80 versus 57 percent). For responses about the effects on visiting attending physicians, the numbers were even higher, with 89 percent of residents and 72 percent of faculty reporting that they believed that gifts or income from industry affected teaching by this group during out-of-hospital dinner lectures and journal clubs. Moreover, 62 percent of residents and faculty believed that annual income or gifts of less than $10,000 could influence an attending physician's teaching. Sixty-five percent of residents and 74 percent of faculty preferred that speakers disclose all financial relationships with industry rather than just report relationships that speakers considered relevant to the educational topic. Although these findings are from a single study in a single institution, they do raise particular concerns about presentations given outside the medical school setting.

Responses

AAMC (2008c) recommends that schools ban the acceptance of industry-supplied food or meals, except in association with ACCME-accredited educational programs. This ban should apply both on and off campus. A few universities (e.g., the University of Michigan and Yale University by 2005)

initiated restrictions some years before the AAMC statement. Schools that ban vendor-provided meals on campus (e.g., Stanford University) may not be explicit about the acceptance of meals at off-site locations, although several schools (e.g., Yale University) also discourage this.

As discussed in more detail in Chapter 6, AMA allows gifts of modest value that are viewed as having some benefit to patients (e.g., meals as part of an educational activity) or the physician's practice (e.g., notepads). The policies of several medical centers (e.g., Wake Forest University, Case Western Reserve University, and the University of Minnesota) are similar to this policy.

In addition to policy changes within the academic community, the Pharmaceutical Research and Manufacturers of America (PhRMA) recently revised its voluntary *Code on Interactions with Healthcare Professionals* (PhRMA2008, effective 2009). Except for the section on scholarships and education funds, the document does not refer specifically to interactions in academic settings. As discussed further in Chapter 6, the revised code more strongly discourages "noninformational" physician-company relationships, such as the provision of tickets to sporting events, token consulting arrangements, speaker training programs at resorts, and meals by sales representatives outside a physician's office or other medical setting.

Industry-Sponsored Scholarships and Training Positions

Issues

Little information on the extent of industry funding for undergraduate and graduate medical education is available, although AAMC has stated that medical schools have become increasingly dependent on such funding for such major activities. The committee is aware of industry-funded residencies or fellowships in a few areas, for example, dermatology residencies funded by companies making dermatologic products (Kuehn, 2005); industry-funded fellowships in rheumatology (Goldblum and Franzblau, 2006); and industry support for psychiatry resident fellowships, awards, and the Chief Resident Leadership Conference (APA, 2008).

The rationale for industry funding of residencies and fellowships seems to rest on physician or researcher shortages in certain specialties and the desire to attract more individuals to these areas through additional industry-supported training positions. For example, the American Academy of Dermatology (AAD) launched an initiative in 2004 to fund 10 dermatology residency positions (Kuehn, 2005). The AAD created a fund to accept donations from the academy, pharmaceutical companies, and other interested parties. Awards were assigned to 10 university programs ($60,000

per year for 3 years), and no recipient would be identified as having been funded by a particular company or companies.

Responses

AAMC (2008c) recommends that academic medical centers establish and implement policies requiring that industry funds for scholarships and similar purposes be given centrally to the administration of the medical center. In addition, industry should have no involvement in the selection of recipients, and no "quid pro quo [should] be involved in any way" (p. 21). The objective is to "prevent the establishment of one-on-one relationships between industry representatives and students and trainees" and minimize "the possibility that these funds will be perceived or used as direct gifts" (p. 21). The committee supports the AAMC recommendations. AMA and PhRMA both permit industry funding of scholarships for medical students, residents, or fellows to attend carefully selected educational conferences when the selection of recipients is made by the academic or training institution.

Changing the Environment or Creating Educational Interventions

To the extent that industry influence operates at an unconscious level, the most effective strategies for reducing the risk of undue influence may involve changing the environment in ways that eliminate or reduce the source, especially when the source offers little or no countervailing educational benefit. That is a major rationale for the policies cited above that eliminate gifts, meals, and other noneducational interactions from the learning environment. Some evidence suggests that the learning environment influences attitudes. Two studies have reported that residents who trained in environments that restricted interactions between industry representatives were less likely than residents who trained in environments without such restrictions to view promotional interactions as being beneficial (Brotzman and Mark, 1993; McCormick et al., 2001). One literature review found weak evidence that trainees who were exposed to educational interventions may be "less accepting of pharmaceutical industry marketing tactics" than those who are not (Carroll et al., 2007, p. e1533). The review noted that two studies that involved industry personnel in the design of the educational intervention found that the participants were more positive toward industry and industry representatives than they were before the intervention.

Some research—including research in academic medical centers as well as community settings (see, e.g., Solomon et al. [2001])— suggests the value of "academic detailing" or educational outreach programs provided by clinical pharmacists or other experts as an objective educational alternative

to the activities of medical product companies. Because these programs are aimed at physicians outside academic institutions, this research is reviewed in Chapter 6.

THE LEARNING ENVIRONMENT IN ACCREDITED CONTINUING MEDICAL EDUCATION

Physicians commit to life-long learning to keep pace with new knowledge and skills and to maintain their current skills. Most state licensing boards, specialty boards, and hospitals require accredited continuing medical education for relicensure, recertification, or staff privileges. Thus, it is important to promote a constructive learning environment in this arena as well as in undergraduate and graduate education. This discussion focuses on accredited continuing medical education. (As noted earlier, this report uses the phrase accredited continuing medical education to refer to education that is presented by accredited providers and is certified for course credits.)

Providers of accredited continuing medical education are more numerous and diverse than providers of undergraduate and graduate medical education. The major ACCME-accredited providers are physician membership organizations (n = 270), publishing/education companies (n = 150), medical schools (n = 123), and hospitals and health care delivery systems (n = 93). In 2008, ACCME had 740 accredited providers of continuing medical education, and state medical societies accredited approximately 1,600 additional providers (ACCME, 2008a, 2009). What ACCME calls "publishing/education companies" are often described as "medical education and communication companies," or MECCs, and that term is used here. According to data reported by the Society for Academic Continuing Medical Education (SACME) for 2006, about 40 percent of medical schools held commercially sponsored "satellite" meetings in conjunction with national professional society meetings, and 70 percent of these meetings were managed by communications companies (SACME, 2007).

Table 5-2 shows the shares of total income, participants, hours of instruction, and activities (all providers) accounted for by several types of accredited continuing medical education providers. Medical schools accounted for a considerably larger share of total hours of instruction than might be expected from their share of the total income received by education providers. In contrast, MECCs (publishing/education companies) account for a considerably smaller share of all instructional hours than of total income.

Accredited continuing medical education programs embedded in medical schools are shaped in part by the missions, culture, and challenges of the larger institution. The programs' members are represented by SACME,

TABLE 5-2 Share of Total Accredited Continuing Medical Education Income, Instruction Hours, Participants, and Activities Accounted for by Major Types of ACCME-Accredited Providers

	Share (as %)			
Provider Organization Type	Total CME[a] Income	Total Hours of CME Instruction	Total CME Participants	All CME-Sponsored Activities
Medical school	17	45	31	30
Publishing/education company	33	9	30	30
Physician membership organization (nonprofit)	35	23	26	20
Other providers	15	23	13	20
TOTAL	100	100	100	100

[a]CME = continuing medical education.
SOURCE: ACCME, 2008a, Tables 2, 3, 4, 7.

which describes its mission as promoting "research, scholarship, evaluation and development" of educational and professional development programs "to enhance the performance of physicians . . . for purposes of improving individual and population health" (SACME, 2008a, unpaged). Professional society programs are also shaped by the missions, culture, and resources of the society. Most MECCs are for-profit organizations. They are represented by the North American Association of Medical Education and Communication Companies, which is "dedicated to providing representation, advocacy, and education for its members" (NAAMECC, 2009).

The curriculum for accredited continuing medical education is also diffuse. All states except Colorado, Indiana, Montana, New York, South Dakota, and Vermont have some requirements for accredited continuing medical education for physicians who want to maintain (reregister) their license (AMA, 2008a). The policies are generally not specific about the content of the accredited continuing medical education, although a number of states have certain content requirements, for example, palliative and end-of-life care or patient safety (AMA, 2008a). Medical specialty boards have more specific and coherent requirements. They have also recently adopted a "maintenance of certification" model for ensuring continuing physician competence, and this model has implications for the future content of accredited continuing medical education.[8] Approximately 85 percent of U.S.

[8] The American Board of Medical Specialties and its 24 member boards have been moving from a process of recertification based on an examination taken once every several years to

physicians are board certified, so recertification requirements affect the majority of physicians (ABMS, 2007).

In addition to accredited continuing medical education, physicians also have access to an array of nonaccredited education programs sponsored by a wide range of public and private organizations. Many conferences sponsored by the National Institutes of Health and other government agencies do not offer credit, although some do. Hospitals sponsor a range of medical staff education programs that do not offer credits. The committee heard testimony that a professional society may organize a scientific meeting of research presentations for which it controls the selection of topics and speakers (ASH, 2008; Kaushansky, 2008). The organization may then seek financial support from industry, often small grants from several companies. Because of limited budget and staff, a small society may not pursue the provision of continuing medical education credits even when it provides safeguards against commercial bias consistent with accreditation standards. When medical product companies organize nonaccredited continuing medical education, the offerings may range from dinner seminars to training on the use of a medical device and satellite symposia at professional society meetings (some satellite symposia offer credit). Some nonaccredited programs controlled by companies may be little more than marketing. Others, such as programs that provide training on the use of a complex new medical device, may meet legitimate education needs, although the presentations may still be more positive about the device than presentations by an independent educational source would be. The committee lacked the resources to investigate nonaccredited activities.

Some medical schools have policies that require their faculty to limit participation in industry-supported programs to programs that meet certain conditions. These conditions may be similar or identical to the standards for accredited continuing medical education (see, e.g., Boston University [2007] and the University of Pittsburgh [2007]).

As noted earlier, the committee commissioned a paper on conflict of interest concerns, policies, and practices in other professions. That paper, which is presented as Appendix C, examines conflicts of interest in law, accounting, engineering, and architecture. In general, other professions differ from medicine in that they have no authority similar to that of physicians to prescribe regulated products for client's personal use and, except to various degrees for law, do not have vulnerable clients.

In some respects, the current system of continuing legal education

---

a maintenance of certification program that emphasizes continuing self-evaluation of practice and knowledge and other activities to maintain competence. Boards may develop self-assessment programs that also offer continuing medical education credit that will meet state licensing board and other requirements.

resembles the system of continuing medical education in decades past. Much continuing legal education is provided by law schools as part of their service mission, although law firms and commercial companies also offer programs. Programs may be offered at no charge or may be paid for by individual lawyers or their firms or employers. Programs sometimes have corporate sponsorship, but the sponsors' products tend to be resources for the lawyer (e.g., software and information resources) rather than for the lawyer's clients and thus do not present the same concerns about bias in presentations that occur in medicine. Although legal continuing education cannot be seen as an exact model for medicine, it does suggest that alternatives (e.g., higher fees and employer subsidies) to the major role of industry funding for continuing medical education may exist.

Industry Funding in Accredited Continuing Medical Education

Survey data from ACCME show that industry funding of accredited continuing medical education increased by more than 300 percent between 1998 and 2007 (ACCME, 2008a, Table 7).[9] Moreover, profit margins increased substantially, from 5.5 percent in 1998 to 31 percent in 2006 (Steinbrook, 2008b). For the many providers of accredited continuing medical education, this combination of increased reliance on industry funding and increased profitability provides strong incentives to resist efforts to curtail such funding.

The contribution of funding from industry (primarily from drug, medical device, and biotechnology companies) varies by the type of provider of accredited continuing medical education (Table 5-3). Funding from industry provides more than half of the total income for medical schools and almost three-quarters of the total income for MECCs. Professional societies (i.e., physician membership organizations) as well as MECCs show a significant margin of income over expenses.

Although professional societies are not as dependent on industry funding for their accredited educational programs as MECCs or medical schools, they receive nearly equal amounts of funding from commercial sources (24 percent) and advertising and exhibit income (25 percent). ACCME's survey does not count the latter as commercial support.

SACME surveys provide additional data on the significance of industry

[9] One widely cited analysis estimated that every $1.00 of industry spending on physician meetings and events generated an average of $3.56 in increased revenue (cited in Walker [2001]; see also CEJA [2008] and NAAMECC and Coalition for Healthcare Communication [2008]). Descriptions of the reported analysis do not indicate the relative weight of accredited versus nonaccredited activities in the estimate or whether accredited continuing medical education was distinguished from other types of meetings, such as promotions. Nonetheless, it suggests a rationale for industry support of a range of educational activities.

TABLE 5-3 Income, Expenses, and Source of Support as Percentage of Income, by Type of Accredited Provider of Continuing Medical Education, 2007

Organization Type (No. of Organizations)	Total Income	Expenses as % of Total Income	Total Commercial Support (% of Total Income)	Advertising and Exhibits Income (% of Total Income)
Nonprofit (physician membership organization) (270)	$887,181	68	$215,388 (24)	$217,907 (25)
Publishing/Education Company [MECC](150)	830,811	74	594,420 (71)	10,831 (1)
School of medicine (123)	427,668	88	245,790 (57)	23,203 (5)
Hospital/health care delivery system (93)	105,014	95	47,498 (45)	7,407 (7)
Nonprofit (other) (38)	160,397	79	78,412 (49)	11,852 (7)
Not classified (33)	55,188	79	29,263 (53)	2,423 (4)
Government or military (15)	69,452	100	255 (0)	376 (0)
Insurance company/managed care company (14)	3,489	193	318 (9)	35 (1)

NOTE: Monetary data for 2007 are in 1,000s of dollars. Data for a third category of income (other) are not shown here. As categorized by ACCME, other income represents income other than commercial support and advertising and exhibit income. Data for providers accredited by state medical societies are not included, but ACCME survey data show that commercial sources accounted for about 25 percent of their income.
SOURCE: ACCME, 2008a (Table 7).

funding for medical school programs. In 2006, the typical (median) medical school received some commercial support for about 45 courses, which represented almost 70 percent of its educational activities (SACME, 2007). About 7 percent of schools reported that the majority of their courses were supported by a single commercial source, and the mean number of such courses across all respondents was two. Respondents also reported that "if commercial support were no longer provided, the typical school would no longer hold 11 courses, representing 23% of the school's courses" (p. 3).

Because they depend on industry for almost three-quarters of their income, MECCs could be severely challenged by an end to direct commercial funding, which some have proposed (Fletcher, 2008), or by a decision by medical product companies to shift their support to academic institutions, as one company recently did (Loftus, 2008). They could still have a role if academic medical centers continued to contract with them to manage or administer some of their continuing medical education programs.

Providers of accredited continuing medical education may solicit industry support for their programs. For example, a medical education company described opportunities to provide educational grants for a large meeting sponsored jointly with an academic medical center, as shown in Box 5-2. Other organizations sell sponsorship opportunities for everything from meeting coffee breaks to hand sanitizers and flash drives.

In addition to support for organizational programs, industry also provides support to individual physicians. On the basis of the findings from a 2004 survey, Campbell and colleagues (2007a) found that 26 percent of physicians reported that industry paid for their admission to continuing medical education meetings and 16 percent reported payments for serving as a speaker or on a speakers bureau.

Conceptually, industry support may be direct or indirect. Direct funding is from the company to the program provider. Indirect funding may occur in several ways. The company may set up a foundation that it substantially controls to provide the funding, or the provider may set up a foundation to receive the funds. Such arrangements may not provide any protection against the company influencing the content of the accredited continuing medical education. Alternatively, the company may provide funds to an intermediary, such as a central continuing medical education office in an academic health center. These arrangements are intended to separate the funding from decisions about the course content. The committee has heard criticisms that despite ACCME requirements that course directors review the course content for bias, the recipient of industry funds may have an implicit understanding that additional industry funds will not be offered in the future if the course does not present topics of interest to the company and use speakers who are favorable to the company's products.

BOX 5-2
Example of a Solicitation of Industry Support (Educational Grants) for a Large Accredited Continuing Medical Education Program

Several support levels are listed below. Please note that educational support is appreciated at any dollar level. Please contact our office for further details. We appreciate that our supporters recognize the need for [the organization] to maintain authority and autonomy in decisions regarding program format, content, and faculty.

Cornerstone Supporter
Total: $195,000
Foundation Supporter
Total: $135,000
Leadership Supporter
Total: $80,000

Satellite Symposia
Open to Cornerstone and Foundation Supporters

1 Breakfast Symposium	Fee: $15,000
1 Lunch Symposium	Fee: $20,000
1 Breakfast Symposium	Fee: $15,000
1 Lunch Symposium	Fee: $20,000
1 Breakfast Symposium	Fee: $15,000

Symposium fee includes:

- Program listing on the [meeting] website, linking to the program provider's online registration site for the satellite symposium.
- Program listing and schedule in the meeting materials distributed to all meeting attendees.
- One complimentary email to the preregistration mailing list for use in promotion of the satellite symposium.
- One time complimentary use of the preregistration mailing list for use in promotion of the satellite symposium (restrictions apply).
- One insert into the delegate literature bag for use in promotion of the satellite symposium.

Concerns About Industry Support for Accredited Continuing Medical Education

The substantial support that industry provides for accredited continuing medical education indirectly subsidizes physicians who pay less

for many accredited continuing medical education programs than they otherwise would. As the preceding section indicates, industry support also contributes to the financial well-being of many educational providers that depend on it for the major part of their income for the provision of accredited continuing medical education.

The committee found little systematic research on other consequences of industry-supported continuing medical education, for example, whether it promotes bias in individual programs or in overall educational offerings. One study published before the adoption of the first ACCME standards for commercial support compared programs funded by rival pharmaceutical companies and found that the programs favored the products of their funders (Bowman, 1986). A study by Orlowski and Wateska (1992) focused on a kind of industry-sponsored activity that provoked considerable criticism and that now is not permitted for accredited education, that is, a program held at a resort with all expenses paid for attendees and with limited time actually devoted to the educational content. The authors found, using actual prescribing data obtained before and after the activity, that this "elaborate promotional technique . . . was associated with a significant increase in the prescribing of the promoted drugs at one institution" (p. 273). The investigators also found that the physicians involved did not believe that the activity would affect their practices.

Another study found that courses on primary care directed by academic faculty covered a broader range of topics than symposia sponsored directly by industry (Katz et al., 2002). Moreover, 91 percent of the industry-sponsored symposia were sponsored by a company that had recently obtained FDA approval for a drug related to the symposium topic. The industry-sponsored symposia did not cover prevention screening, dermatological diagnoses, child abuse, alcoholism, or the technology resources available for clinicians, which were considered important in the academic program. In that study, the university-based accredited continuing medical education courses received funding from multiple companies through a MECC to the university. University faculty determined the content of their courses, and the MECC handled marketing and meeting logistics. During meal breaks at these courses, symposia funded by industry were also offered.

Unfortunately, much information about accredited continuing medical education, particularly that offered by for-profit providers, is not based on good data but, rather, is based on personal experiences with covert relationships with providers or inferences made on the basis of the nearly total dependence of these providers on pharmaceutical, medical device, and biotechnology companies. One 2008 article, based on personal experience, describes how accredited continuing medical education providers can tailor programs to secure company grants (Gilbert, 2008, unpaged). A commer-

cial provider selected a program concept to "provide a platform for one of the sponsors," which was working on a drug covered by the program. The provider also organized informal workshops with experts who were hired on the basis of their support for the sponsor's message.

Using a checklist that they developed to assess bias in education programs, Takhar and colleagues (2007) concluded that 9 of the 17 continuing medical education programs that they assessed were biased (e.g., by limiting the discussion to the sponsor's product and ignoring alternatives). Work is needed to validate this and other instruments that are intended to be used to assess bias in presentations retrospectively or identify presentations at risk of bias during the planning stage (see, e.g., Barnes et al. [2007]).

The Senate Finance Committee staff report on the use of educational grants by pharmaceutical manufacturers noted that ACCME's reports documented numerous cases of undue influence by companies over "supposedly independent educational programs" (Finance Committee, U.S. Senate, 2007, p. 2). For example, during 2005 and 2006, 18 of 76 program providers were found to be out of compliance with at least one of the ACCME standards related to independence, and some were cited for being under the improper influence of industry.

More specific information on industry practices comes from litigation. Prompted in many instances by whistleblower complaints, the U.S. Department of Justice as well as state attorneys general have filed charges against a number of pharmaceutical and medical device companies for illegal practices related to purported educational activities as well as speaking and writing arrangements. In some cases, one focus of litigation has been the giving of educational grants as an inducement to use the company's products, which can be illegal under the Medicare law. In other cases, the focus has been on industry efforts to bias the content of educational programs and presentations, particularly as part of efforts to promote the off-label use of drugs (i.e., for purposes not approved by the FDA), which is also illegal.[10]

Box 5-3 lists some of the cases in which settlements have been reached. Internal company documents that were made public as a result of the first case described in the box provided insights into the use of speakers bureaus (which included chairs of neurology departments), "educational" teleconferences, and grants to medical education companies (with multiple ties to the company) to further marketing objectives for the drug Neurontin (gabapentin) (Steinman et al., 2006; see also Landefeld and Steinman [2009]).

[10] In 1997, the FDA provided guidance on the characteristics of industry-supported educational activities that distinguish them from promotional activities, which are subject to the labeling and advertising provisions of the Federal Food, Drug, and Cosmetic Act (FDA, 1997). This guidance stresses the role of voluntary oversight, for example, through accreditation; it explicitly disavows an interest in regulating programs.

BOX 5-3
Settlements Involving Educational Activities and Speaking and Writing Arrangements

In 2004, Warner-Lambert paid $430 million to settle U.S. Department of Justice charges that the company promoted off-label uses of the drug Neurontin in violation of the Food, Drug, and Cosmetic Act. "This illegal and fraudulent promotion scheme corrupted the information process relied upon by doctors in their medical decision making, thereby putting patients at risk." Tactics included "[paying] doctors to attend so-called 'consultants meetings' in which physicians received a fee for attending expensive dinners or conferences during which presentations about off-label uses of Neurontin were made; . . . [and sponsoring] purportedly 'independent medical education' events on off-label Neurontin uses with extensive input from Warner-Lambert regarding topics, speakers, content, and participants. . . . In at least one instance, when unfavorable remarks were proposed by a speaker, Warner-Lambert offset the negative impact by 'planting' people in the audience to ask questions highlighting the benefits of the drug" (DOJ, 2004, unpaged).

In 2007, Orphan Medical, Inc., agreed to pay $20 million and accept a corporate integrity agreement to settle charges that it had illegally promoted the drug Xyrem (sodium oxybate) for off-label uses. Among other charges, the company was accused of using unrestricted "educational grants" as an inducement for off-label use and paying tens of thousands of dollar in speaker fees to physicians for their promotion of these uses. One of these physicians has been charged criminally for his behavior (DOJ, 2007b). The associated corporate integrity agreement required, among other provisions, that the company create procedures to ensure that sponsored continuing medical education and educational activities be independent and nonpromotional (OIG, 2007).

In 2008, in a stipulated agreement filed in Oregon, Merck & Co, Inc., agreed to pay $58 million to 30 states and to end certain deceptive practices used to promote the drug Vioxx (rofecoxib). The stipulation prohibits, among other practices, company use of ghostwriting of published journal articles and the nondisclosure of promotional ties with speakers at independent continuing medical education programs (Oregon DOJ, 2008a).

The conditions associated with the settlement in the case specified requirements for the company's reporting of its support for continuing medical education and its financial relationships with speakers and participants (OIG, 2004).[11]

[11] The corporate integrity agreement was signed by Pfizer, which had purchased Warner-Lambert, which, in turn, was the parent company of Parke-Davis, the company named in the case.

Responses to Concerns About Bias in Industry-Funded Accredited Continuing Medical Education

Responses by Private Organizations

Expanded industry support for accredited continuing medical education and the involvement of commercial firms began to become a significant concern in the 1980s and led to ACCME-developed guidelines on commercial support in 1987 and then ACCME-developed standards in 1992. These standards have been criticized as doing little to curb industry influence over the content of accredited continuing medical education (see, e.g., Relman [2001, 2003]; see also Ross et al. [2000], Krimsky [2003], and Brody [2007]). In 2004, ACCME issued new, more restrictive standards.

The accreditation standards now require the disclosure of conflicts of interest by meeting planners as well as speakers. They also require the review of the educational content for bias and the resolution of conflicts of interest in some fashion (e.g., by finding an alternative speaker or identifying and eliminating biased content in a presentation). In addition to the standards, ACCME has developed tools (e.g., definitions, frequently asked questions, and slide presentations) to help educational providers with program implementation.

The SACME survey mentioned above reported that academic providers found the 2004 standards to be difficult to implement (SACME, 2007). Only 5 percent of the respondents considered the standard related to resolving conflicts of interest to be easy to implement. Slightly less than half of the respondents thought that the standards had reduced bias a little or somewhat.

In 2008, the ACCME board of directors adopted a statement that indicated that accredited continuing medical education providers "cannot receive guidance, either nuanced or direct, on the content of the activity or on who should deliver that content" (ACCME, 2008b, p. 3). The organization also announced that it was devoting more resources to implementation and enforcement, which would eventually require an increase in member fees (ACCME, 2008b). In addition, ACCME issued a request for comments on a proposal related to commercial support, which included as options the elimination of commercial support, the continuation of the current situation, and the development of a new paradigm (ACCME, 2008d). The executive summary for the November 2008 board of directors meeting states that analysis of the comments is continuing and that action is not anticipated before the end of 2009 (ACCME, 2008c).

Notwithstanding the changes in ACCME standards, criticisms of industry funding and influence continue (see, e.g., Steinbrook [2005, 2008b] and Fletcher [2008]). ACCME's limited resources for monitoring adherence to

its standards (as of early 2008, it had approximately a dozen staff members) are also a concern (Kopelow, 2008).

Other issues involve the monitoring of the content of presentations. Program-by-program and presentation-by-presentation assessments for bias are labor-intensive activities, and instruments for the systematic assessment for bias need further development and validation. The committee found no studies describing or evaluating the effectiveness, burdens, and adverse consequences of such monitoring for bias overall or by category of accredited continuing medical education provider. ACCME requirements for monitoring may stimulate research in this area.

Some critics raise broader questions about the value, goals, and structure of the current system of accredited continuing medical education (see, e.g., Fletcher [2008]). Some have also proposed ending direct industry support for continuing medical education (see, e.g., Brennan et al. [2006], Fugh-Berman and Batt [2006], CEJA [2008], and Fletcher [2008]). In 2008, the AMA House of Delegates referred back to its Committee on Ethical and Judicial Affairs a proposal that physicians and organizations not accept industry funding for professional medical education (AMA, 2008c; see also Relman [2008]). The summary of a 2008 consensus conference held at the Mayo Clinic describes a conclusion that continuing medical education requires a "strategic management process that focuses on the integrity of an enterprise" and that deals "in a convincing, transparent and accountable manner issues such as commercial interest influence, conflicts of interest, bias, sources of evidence and the quality of product, process and delivery" (Kane, 2008, p. 8). It also stressed the need for research (and funding for research) to guide reforms.

In a 2008 report on industry funding of medical education, AAMC recommended that academic medical centers set up audit procedures to assess compliance with ACCME standards. The report observed that given "the heavy dependence by academic medical centers on industry funding" for continuing medical education, it was essential that they comply with "evolving" ACCME standards and take other steps to ensure the independence of their program offerings (AAMC, 2008c, p. 19). The report also recommended that academic medical centers establish a central office through which all requests for industry support and the receipt of funds for continuing medical education would be coordinated and overseen. It further proposed that institutions should prohibit faculty, students, residents, and fellows from participating in non-ACCME accredited industry events that are labeled as continuing medical education. Also, if medical centers allow faculty participation in industry-sponsored, FDA-regulated programs, they should set standards for appropriate faculty involvement.

In its revised code of conduct, PhRMA includes provisions on industry support for continuing educational programs. With an eye to federal

kickback laws, it advises companies to separate decision making about educational grants from sales and marketing units and to "develop objective criteria for making CME grant decisions to ensure that . . . the financial support is not an inducement to prescribe or recommend a particular medicine or course of treatment" (PhRMA, 2008). For nonaccredited educational activities, the code provides that the organizers of the activity should control its content, faculty, materials, and similar details. As noted earlier, one pharmaceutical company announced that it would no longer fund educational programs offered by MECCs.

Most medical school policies reviewed by the committee already state that their programs should meet the standards for commercial support set forth by ACCME. Some have instituted further restrictions. In 2007, Memorial Sloan-Kettering Cancer Center announced a 6-month trial period during which it would no longer accept industry funding for its continuing medical education programs (industry provided about 25 percent of total funding for continuing medical education at that institution). To reduce costs, off-site programs were moved on-site, free lunches were eliminated, advertising was cut, and fewer external speakers were used. Although the fees for external participants were raised by 10 to 20 percent, program attendance stayed the same (Kovaleski, 2008). The ban on industry funding is now permanent. At least one other institution has also announced that it will no longer accept direct industry funding for specific accredited continuing medical education courses either on or off campus, nor will it accept payments from third parties that have received commercial support (Stanford University School of Medicine, 2008). Industry support is, however, permitted if it is not designated to a specific subject, course, or program but is for use in a broadly defined field and is provided through a central university office for continuing medical education.

Responses by Public Agencies

As described above, the U.S. Department of Justice and state attorneys general have charged a number of companies with illegal practices related to the funding of educational programs, including accredited programs in some instances. In addition, in its 2003 compliance guidelines for pharmaceutical manufacturers, the Office of the Inspector General (OIG) of the U.S. Department of Health and Human Services identified the provision of educational grants as an activity that place a company at high risk for violating federal antikickback rules and certain FDA regulations (OIG, 2003). These compliance guidelines advise manufacturers to separate their grant-making activities from their sales and marketing activities to "help insure that grant funding is not inappropriately influenced by sales or marketing motivations and that the educational purposes of the grant are legitimate"

(p. 21). Other activities identified as having a high potential for fraud and abuse include the provision of gifts, entertainment, and personal services compensation arrangements. The OIG guidelines also recommend (pp. 20–21) that manufacturers

1. separate grant-making functions from sales and marketing functions;
2. establish objective criteria for awarding grants that do not take into account the volume or value of the recipient's purchases;
3. establish objective criteria for awarding grants that ensure that the funded activities are bona fide; and
4. refrain from controlling speakers or content of educational activities funded by grants.

The 2007 Senate Finance Committee staff report cited above concluded that most large pharmaceutical companies had established written policies and procedures on educational grants, limited sales representatives from soliciting requests or promising funding, and established a centralized mechanism for administering grants.

GHOSTWRITING, SPEAKERS BUREAUS, AND INDEPENDENCE OF PUBLICATIONS AND PRESENTATIONS

Concerns about Ghostwritten Publications, Participation in Speakers Bureaus, and Other Industry-Controlled Work

Two hallmarks of academic integrity are intellectual independence and accountability for one's work. Certain practices by medical school faculty create a hidden curriculum that subverts the professional values endorsed by the formal curriculum. One example is taking credit as the author of a manuscript prepared by an unacknowledged or inadequately acknowledged industry-paid writer. (An adequate acknowledgment would specify the roles of these writers, for example, as the preparers of the first draft, as well as the roles of the listed authors.) Another example is participating in an industry speakers bureau or other long-term speaking arrangement with a company, regardless of how the relationship is labeled. One concern is that ongoing company payments for presentations (and travel to attractive locations) create a risk of undue influence. A second concern that is frequently tied to the speakers bureau label is that the company exerts substantial control over the content of a presentation. Industry influence in these arrangements may be direct (e.g., when a talk and slides are largely or entirely prepared by someone else or when speakers are instructed to provide the company-prepared responses to questions and avoid the favorable mention of competing products). Influence may also be less direct (e.g.,

when a company-trained and company-paid physician modifies talks to fit the objectives of the company) (see, e.g., Elliott [2006] and Carlat [2007]). The committee recognizes that companies have an interest in some oversight of presentations for a variety of reasons, including the need to comply with FDA prohibitions on promoting the use of drugs for the treatment of conditions not approved by the agency.

Serving on speakers bureaus appears to be common in clinical medicine. A 2006 survey of academic-industry relationships found that 21 percent of clinical department chairs reported being on a speakers bureau (whereas 2 percent of nonclinical department chairs reported being on a speakers bureau) (Campbell et al., 2007b). As reported earlier, another survey, which was not limited to academics and which asked less specific questions, found that 16 percent of physicians reported serving on a speakers bureau or as a speaker, which could have involved a single presentation (Campbell et al., 2007a). ACGME has expressed concern about "a new variation of a promotional activity in which residents and even medical students receive slides, lecture materials and honoraria and subsequently act as 'experts,' delivering the packaged information at continuing medical education events" (ACGME, 2002, p. 3).

Unacknowledged industry influence over publications is also common. In one study, 13 percent of research articles in major biomedical journals had "ghost" authors, that is, people who filled the criteria for authorship but who were not listed as authors (Flanagin et al., 1998). None of these ghost authors was even acknowledged in the paper. A review of documents obtained during litigation against a major pharmaceutical company concluded that review manuscripts were often prepared by writers for medical publishing companies but authorship was "subsequently attributed . . . to academically affiliated investigators who often did not disclose industry financial support" (Ross et al., 2008, p. 1800). One incident illustrates that such ghostwriting may be discovered only by accident. An academic physician reported that a MECC sent her a draft manuscript of a review article commissioned by a drug company and invited her to be its "author." She declined, but she was subsequently asked by a journal to review an article that was similar to that article and that now had another author (Fugh-Berman, 2005; see also Eaton [2005]). The analysis by Steinman and colleagues (2006) of documents obtained through litigation cited earlier found that those documents describe plans for recruiting academic authors of a series of ghostwritten articles to be prepared by a medical education company. Box 5-3 included examples of company settlements with the Department of Justice related to speaking and writing arrangements.

Another concern about industry relationships is that academic authors of research articles may not have full access to the data from an industry-sponsored study. This issue was discussed in Chapter 4.

In the setting of medical education, the question is not whether assistance by professional writers and others may improve publications and help busy researchers get important, objectively presented findings into print; it may do both. The questions are whether the assistance is hidden, whether it is intended to promote a company's interests rather than present unbiased information, and whether the author takes credit for work that he or she did not do and thus misrepresents the provenance of the article. Such arrangements (which are essentially gifts) send the wrong message about the values of intellectual independence, professional ethics, accountability, and evidence-based medicine. In the context of research, they raise questions about the objectivity of research reports that other researchers as well as practitioners and developers of practice guidelines rely on.

Responses to Concerns About Independence and Accountability in Writing and Speaking

Medical journal editors (including the International Committee of Medical Journal Editors and the World Association of Medical Editors) have taken steps to eliminate ghostwriting (see, e.g., Rennie et al. [1997], Davidoff et al. [2001], ICMJE [2008], and WAME [2008]). As stated by the International Committee of Medical Journal Editors, "[a]ll persons designated as authors should qualify for authorship, and all those who qualify should be listed" (ICMJE, 2008, p. 3; see also Ross et al. [2008]). The objective of authorship policies is to eliminate unethical practices and generally not to preclude legitimate and properly acknowledged writing assistance (see, e.g., Lagnado [2002] and Woolley et al. [2006]).

As described in Chapter 3, one journal has revised its conflict of interest disclosure form to include questions intended to detect commercial sponsorship and unacknowledged authors after concluding that such questions were necessary to detect ghostwritten or promotional submissions (AFMI, 2008). In its disclosure form for continuing medical education programs, the same professional society asks several questions about relationships with speakers bureaus (e.g., whether an individual is acting independently or as an agent) as well as questions about the receipt of assistance with manuscript preparation from commercial entities (AAFP, 2006b).

In its 2008 report on medical education, AAMC recommended, "[a]cademic medical centers should prohibit physicians, trainees, and students from allowing their professional presentations of any kind, oral or written, to be ghostwritten by any party, industry or otherwise" (AAMC, 2008c, p. 22). It noted that properly acknowledged collaborations with industry personnel or medical writers is not ghostwriting. The report also recommends that participation in industry-sponsored speakers bureaus be discouraged.

A few medical school policies reviewed by the committee mention speakers bureaus by name. For example, the University of Massachusetts views speakers bureaus as an "extension of the marketing process" and forbids faculty participation in them. The Mayo Clinic has long prohibited faculty from speaking on behalf of industry, and its current policy prohibits participation in the speakers bureaus of commercial firms because the linkage would imply endorsement by the Mayo Clinic (personal communication, Marianne Hockema, Administrator, Office of Conflict of Interest Review, Mayo Clinic, September 19, 2008). Faculty at the University of Louisville (2008) are "strongly discouraged" from serving as speakers hired by vendors (p. 4). A policy recently adopted by the Johns Hopkins University School of Medicine (2009) states that faculty may not participate on-site or off-site in "activities with any of the following characteristics . . . a company has the contractual right to dictate what the faculty member says; a company (not the faculty member) creates the slide set (or other presentation materials) and has the final approval of all content and edits; the faculty member receives compensation from the company and acts as the company's employee or spokesperson for the purposes of dissemination of company-generated presentation materials or promotion of company products; and/or a company controls the publicity related to the event" (p. 7). The policy notes that some of these activities occur in the context of speakers bureaus but it is the conditions of an activity that determine whether it is permissible.

In addition, a few medical schools (e.g., the University of California at San Francisco, the University of Louisville, and the University of Colorado) forbid ghostwriting (using that term). A few other medical schools (e.g., Stanford University, the University of Missouri, Emory University, and the University of Rochester) cover the practice of ghostwriting by forbidding medical school personnel from publishing, under their own name, articles that are written entirely or in significant part by an industry employee.

The ACCME standards for commercial support require that presenters disclose relevant financial relationships. They provide no explicit guidance or reference to the appropriateness of commercial assistance in the preparation of talks.

The 2008 PhRMA *Code on Interactions with Healthcare Professionals* notes that companies and speakers should understand the difference between (accredited) continuing medical education and company-sponsored speaker programs (PhRMA, 2008). For the latter, "[s]peaker training is an essential activity because the FDA holds companies accountable for the presentations of their speakers" (p. 9). This is a reference to FDA's ban on company promotion of the use of a medication for the treatment of conditions that have not been approved by the agency (FDA, 1997). The

PhRMA code specifies that company policies should provide a cap on the total annual amount that it will pay a speaker and address the "appropriate number of engagements for any particular speaker over time" (p. 10).

RECOMMENDATIONS

Medical Schools and Residency Programs

Policies on Relationships with Industry

This chapter has documented the extensive relationships that exist between industry and medical institutions, faculty, students, and residents and the concerns that have been raised about the risks that these relationships pose to the basic educational missions of academic medical centers and the lack of benefits from such relationships, such as those that support academic-industry collaborations in medical research. It has cited research indicating that even small gifts can be influential and has reviewed the recommendations of organizations such as AAMC and PhRMA. The committee concluded that it is time for medical schools to end a number of long-accepted relationships and practices that create conflicts of interest, threaten the integrity of their missions and their reputations, and put public trust in jeopardy. The risks are substantial and are not offset by meaningful benefits.

RECOMMENDATION 5.1 For all faculty, students, residents, and fellows and for all associated training sites, academic medical centers and teaching hospitals should adopt and implement policies that prohibit

- **the acceptance of items of material value from pharmaceutical, medical device, and biotechnology companies, except in specified situations;**
- **educational presentations or scientific publications that are controlled by industry or that contain substantial portions written by someone who is not identified as an author or who is not properly acknowledged;**
- **consulting arrangements that are not based on written contracts for expert services to be paid for at fair market value;**
- **access by drug and medical device sales representatives, except by faculty invitation, in accordance with institutional policies, in certain specified situations for training, patient safety, or the evaluation of medical devices; and**
- **the use of drug samples, except in specified situations for patients who lack financial access to medications.**

Until their institutions adopt these recommendations, faculty and trainees at academic medical centers and teaching hospitals should voluntarily adopt them as standards for their own conduct.

This recommendation has several targets, most of which focus on promotional relationships. One target is the acceptance by faculty or trainees of items of material value (including small gifts and meals) from industry except in certain situations. These situations, which should be defined in institutional policies, include (1) appropriate payment for legitimate services (such as contracts, grants, and consulting arrangements); (2) charitable donations, which should be given to the institution; and (3) sharing of research materials or data. Under appropriate transfer agreements, the sharing of research materials or data is encouraged, as it promotes medical research. This recommendation covers not only physical gifts, such as pens, notepads, and meals, but also preferences, such as paid speaking engagements that are intended as rewards or inducements. Consulting arrangements and drug samples are discussed further below.

The second target of this recommendation is the involvement of faculty or trainees in presentations or publications for which they cannot ethically claim credit or intellectual independence. Although no physician or researcher should accept authorship of a ghostwritten academic publication (see the discussion earlier in this chapter), failure to meet this standard is particularly troublesome when it involves faculty who have a special obligation to demonstrate intellectual independence and to act as role models. For similar reasons, faculty should not participate in speakers bureaus and similar promotional activities in which they either present content directly controlled by industry or formulate their remarks to win favor and continued speaking fees. If institutions fail to adopt these recommendations, then acceptance of authorship for ghostwritten publications or industry-controlled presentations would constitute a gift to be disclosed to the institution even if the institution's policies do not explicitly mention these arrangements as gifts.

The recommendation's third target is consulting arrangements. Faculty should engage only in bona fide consulting arrangements that require their expertise, that are based on written contracts with specific tasks and deliverables, and that are paid for at fair market value. As part of their administration of conflict of interest policies, university review of faculty consulting and other contracts is prudent and desirable.

The fourth target of this recommendation concerns access to educational environments by sales representatives of pharmaceutical, medical device, or biotechnology companies. Clinical teaching should be done by faculty, not by marketing agents. The recommended restrictions on site access should not discourage appropriate and productive research collabora-

tions between industry and academic researchers. In addition to promoting scientific progress and the development of useful products, collaborations can provide educational benefits to medical students, graduate students, and postdoctoral fellows who might participate in legitimate collaborative research projects with industry under proper supervision.

As described earlier, the AAMC recommendations and some medical school policies set stringent restrictions on access by pharmaceutical sales representatives but establish slightly less restrictive conditions for access by representatives of medical device companies. The recommendations and policies reflect assessments that access by device representatives—if they are properly managed and appropriately limited—can contribute to patient safety. Nonetheless, the expectation is that faculty will quickly learn how to use complex new devices, including relevant surgical techniques, and will then instruct and supervise residents and fellows rather than rely on company representatives to do so. Access under these circumstances would occur after the institutional purchase of a complex device. For the purposes of device evaluation, access by the device representatives would occur before purchase of the device.

The fifth target of this recommendation, which covers drug samples, presents difficult issues. Caring for patients who cannot afford needed drugs is frustrating for physicians who are trying to meet their professional obligations to act in their patients' best interests. Despite the aid provided through Medicaid and Medicare, other public programs, and the patient access initiatives of pharmaceutical companies, many patients are not eligible for such aid and cannot afford to continue to take medications after they have used a sample. Moreover, although physicians and others may believe that drug samples allow low-income patients access to drugs that they could not readily obtain otherwise, this chapter has cited research that suggests that most samples are not, in fact, given to indigent patients and that access to samples may change trainee behavior such that they move away from practicing evidence-based and lower-cost care. Drug samples are not a satisfactory answer to the serious problem of the lack of affordability of medications for many patients, but the committee was reluctant to call on physicians to abandon them completely in the short term.

For academic medical centers, the use of drug samples may often be managed without a direct interaction between a physician and a company representative. Thus, AAMC recommends and this committee agrees that samples (if the institution permits them) should, whenever possible, be centrally managed in ways that allow timely and appropriate patient access.

In the absence of such centralized arrangements, institutions should limit the provision of free drug samples and provide them only to patients who lack financial access to medications in situations in which generic alternatives are not available and the sample medication can be continued at

little or no cost to the patient for as long as it is needed. They should also help physicians and patients use alternative public and private resources to obtain the needed medications. The proposal by the Medicare Payment Advisory Commission for company reporting and U.S. Department of Health and Human Services analysis of data about the distribution of drug samples cited earlier in this chapter could, if it is adopted, produce helpful information to guide future policies.

The elements of this recommendation apply both to campus settings and to off-site settings, for example, off-site locations for professional meetings and educational programs. They also apply to volunteer faculty who provide clinical education in their offices or in community hospitals. Chapter 6 presents a parallel recommendation (Recommendation 6.1) for physicians who are not affiliated with academic institutions. That chapter also presents a comprehensive recommendation (Recommendation 6.2) that calls for medical product companies to change their policies to be consistent with these recommendations. The committee recognizes that it takes time for academic medical centers to develop policies. It recognizes the value of policy development processes that involve the assessment of local conditions, the inclusion of those who will be affected, and investigation of the experiences of similar institutions.

Until institutions act, faculty, students, and trainees should still change their own behavior so that it is in line with the recommendations presented above. In addition, consistent with Recommendation 9.1, the committee encourages AAMC, AMSA, and similar membership organizations to continue or initiate survey, monitoring, and other activities to promote the reform of conflict of interest policies in medical education.

Education on Relationships with Industry

RECOMMENDATION 5.2 Academic medical centers and teaching hospitals should educate faculty, medical students, and residents on how to avoid or manage conflicts of interest and relationships with pharmaceutical and medical device industry representatives. Accrediting organizations should develop standards that require formal education on these topics.

Changing the environment within educational institutions is important, but medical schools also need to prepare trainees for practice in environments that may be characterized by more permissive standards of conduct regarding drug and device marketing. Faculty will continue to experience a range of situations in which they will interact with industry representatives and will also need to be prepared to act as educators and role models on industry relationships.

The committee recognizes that the evidence on the effectiveness of educational programs of this sort on physician attitudes and behaviors is not strong, but it believes that a basic level of education supports the development of core competencies and prepares students and trainees for future practice. The establishment of educational standards will help ensure that such education is of high quality and receives appropriate attention.

Accredited Continuing Medical Education

The members of the committee had extensive internal discussions about industry support for accredited continuing medical education. Overall, there was general agreement that continuing medical education has become far too reliant on industry funding and that such funding tends to promote a narrow focus on products and to neglect the provision of a broader education on alternative strategies for managing health conditions and other important issues, such as communication and prevention. Given the lack of validated and efficient tools for preventing or detecting bias, industry funding creates a substantial risk of bias, to the extent that industry-reliant providers want to attract industry support for future programs. Although the committee did not reach agreement on a specific path to reform, it concluded that the current system of funding is unacceptable and should not continue.

RECOMMENDATION 5.3 A new system of funding accredited continuing medical education should be developed that is free of industry influence, enhances public trust in the integrity of the system, and provides high-quality education. A consensus development process that includes representatives of the member organizations that created the accrediting body for continuing medical education, members of the public, and representatives of organizations such as certification boards that rely on continuing medical education should be convened to propose within 24 months of the publication of this report a funding system that will meet these goals.

One option is for this broad-based consensus development process to be convened by the member organizations of ACCME. As described earlier in this chapter, they represent medical specialty boards (American Board of Medical Specialties), hospitals (AHA and the Association for Hospital Medical Education), organized medicine (AMA), medical schools (AAMC), medical specialty societies (CMSS), and state licensure boards (Federation of State Medical Boards). Although these organizations have interests in continuing medical education and in ensuring that continuing education is

free of bias and supports core competencies, they do not all have a vested interest in the current system of funding that education.

The consensus development process convened by this or another group should be broad based and should also include representatives of other medical education accrediting bodies (LCME and ACGME), other interested state and federal agencies, public interest and patient advocacy groups, and organizations such as specialty certification boards that rely on continuing medical education. It should also include providers of accredited continuing medical education and industry funders. The deliberations should take into account the findings of other groups that have analyzed funding for continuing medical education or that have made recommendations about improving continuing medical educational methods.

Most committee members believed that a near-term end to industry funding would be unacceptably disruptive for the major providers of accredited continuing medical education, including medical schools and professional societies, which together provide 68 percent of the total number of hours of this type of education (see Table 5-2). A SACME survey found that 77 percent of respondents said that immediate elimination of commercial support would substantially reduce the number of courses at their academic centers and the scope of their programs and could potentially lead to the elimination of programs (SACME, 2008b). Eliminating all industry funding without having in place an alternative model could have other adverse consequences. For example, a surgical society may hold a premeeting accredited workshop involving hands-on teaching of surgical techniques, typically supported by indirect funds from industry. In the committee's experience, the costs of setup and materials for multiple simultaneous workshops can be several million dollars and would be hard to cover by payments from attendees. Furthermore, other innovative educational formats—for example, Internet-based training, simulation-based training, and performance improvement learning activities—also require funding for start-up and updating costs that could be prohibitive for providers to self-fund or fund entirely through nonindustry sources.

A majority of the committee supported the use of a consensus development process to develop a new funding system for accredited continuing medical education that would be free of industry influence but that would leave open the possibility of certain forms of indirect industry funding under conditions that minimized the risk of undue influence on program content. Some committee members supported the use of a consensus development process to develop an alternative funding model but believed that no form of direct or indirect industry funding was acceptable.

Among the options that the consensus development activity could consider are proposals for some kind of pooled funding mechanism. For example, companies could grant funds to some independent central or regional

entity that would establish educational priorities and make decisions—perhaps within broad categories—about the distribution of funds on the basis of an independent review of applications from education providers.

Both direct company funding to institutions for specific continuing medical education programs and direct company provision of unrestricted grants to institutions offer clear opportunities for undue influence, particularly for continuing medical education providers that also receive the great majority of their funding overall from companies. A plan for a system free from industry influence would exclude such funding as well as funding from company-controlled foundations.

The committee recognizes that industry willingness to provide funds under a restructured system of funding accredited continuing medical education might be quite limited. Thus, the consensus development process would also need to consider alternative means of financing, steps to reduce program costs, and other strategies that would support high-quality continuing medical education. Options include increased fees for attendees; subsidies from academic medical centers as part of their educational missions; elimination of expensive program locales and amenities; reduced payments to speakers; collaboration among education providers to share the costs of developing certain expensive programs; and rethinking the purpose and methods of continuing medical education, as is already being done in the development of programs for the maintenance of certification by specialty societies. Higher fees might be a particular burden for physicians with lower-than-average professional incomes, including rural physicians and physicians serving disadvantaged populations.

The committee members who opposed any industry funding of continuing medical education through any mechanism believed that physicians (or their employers) should bear the entire cost of accredited continuing medical education that is required for renewal of licensure and specialty certification. Even giving industry funding and program decision-making responsibility to a central office within a medical school, MECC, or other institution would unnecessarily retain conflicts of interest over the choice of course topics, directors, content and speakers, and the leadership of the continuing medical education office. In the view of these committee members, all industry support for accredited continuing medical education should be rejected, just as it is for most undergraduate and graduate medical education.

In the process of hearing testimony relevant to the issue of funding of continuing medical education, many committee members came to the conclusion that a number of other fundamental problems about the focus and the effectiveness of continuing medical education warranted attention. These issues were outside of the purview of the committee. Some will be considered by another committee of the Institute of Medicine, which is

charged with making recommendations about the promotion of more effective methods of life-long education for health professionals (IOM, 2009). Analyses of the financing of continuing medical education are planned in conjunction with that project. Those analyses may provide a better understanding of the implications of different proposals about financing in the context of other changes in the system.

The committee focused on accredited continuing medical education. As noted earlier, some nonaccredited activities with industry support are educational rather than promotional and apply safeguards to prevent bias in the selection of topics, speakers, and materials presented. One example is the scientific symposium that is organized and controlled by a professional society and supported by unrestricted grants from companies. Such meetings may be particularly important for fields with many Ph.D. researchers and relatively restricted budgets. Another example is training in the use of complex medical devices provided by medical device companies under the conditions outlined elsewhere in this report (e.g., no gifts or inducements to use the product).

Other Recommendations in This Report

In addition to the recommendations in this chapter, other recommendations in this report would affect institutions that provide undergraduate, graduate, or continuing medical education. The standardization of institutional disclosure policies and formats (Recommendation 3.3) would require work to change policies and information systems, but in the long term, it should make institutional policies less burdensome across all educational institutions—as well as for individuals who must disclose potential conflicts of interest. Academic medical centers, which have repeatedly been embarrassed by revelations of incomplete and inaccurate faculty disclosures of payments from industry, would benefit from a national program of company reporting of payments to physicians and researchers that would allow the verification of certain disclosures (Recommendation 3.4). Because that reporting program would also cover payments to academic medical centers and other providers of medical education, it could provide an incentive for the adoption of institution-level conflict of interest policies, as recommended in this report (Recommendation 8.1). Accrediting organizations, membership groups such as AAMC and CMSS, and government agencies should also develop incentives for institutions to adopt and implement conflict of interest policies (Recommendation 9.2).

Adoption of the recommendation related to the conduct of research in which an investigator has a financial interest would encourage the development of management plans to protect trainees involved in such research if the institution concludes that the participation by the investigator with a

conflict of interest in the research is essential (Recommendation 4.1). To the extent that physicians embrace Recommendation 6.1 to reject gifts and similar ties, it would reduce dissonance when students, trainees, and faculty interact with others in the medical community at professional society meetings and in other contexts. Further steps by companies to reform their policies and practices on gifts and payments to physicians (Recommendation 6.2) would allow medical centers to focus more attention on other issues, for example, consulting and other contractual arrangements. Finally, academic institutions can play an important role in implementing a program of research on conflict of interest (Recommendation 9.2).

6

Conflicts of Interest and Medical Practice

A position statement of the American College of Physicians (ACP) observed that "[p]hysicians meet industry representatives at the office and at professional meetings, collaborate in community-based research, and develop or invest in health-related industries. In all of these spheres, partnered activities often offer important opportunities to advance medical knowledge and patient care, but they also create an opportunity for the introduction of bias" (Coyle et al., 2002a, p. 397). This chapter examines these relationships and the sources of conflicts of interest in the context of practicing physicians' primary professional obligations.

Professionals are granted important privileges—including the power to set educational and ethical standards—in return for maintaining competence, being trustworthy and ethical, and working to benefit patients and society. The power to set standards creates certain tensions. As Pellegrino and Relman (1999) have written, "[t]oo often, ethical goals have been commingled with protection of self-interest, privilege, and prerogative. Yet, effacement of self-interest is the distinguishing feature of a true profession that sets it apart from other occupations" (p. 984).

In the realm of patient care, threats to professionalism and questions about conflicts of interest may arise in several situations, some of which involve pharmaceutical, medical device, and biotechnology companies and some of which do not. This chapter focuses on physician financial relationships with industry that usually are not intrinsic to medical practice and that can be avoided. These relationships create conflicts of interest when physicians

- accept company gifts of various kinds, including meals and drug samples;

- act as promotional speakers or writers on behalf of companies; or
- have a financial interest in a medical product company whose products they prescribe, use, or recommend.

In addition, conflicts of interest arise from the ways in which physicians are paid for their services. These conflicts are inherent in any payment system, although each payment method raises different concerns. Physician ownership of health care facilities and self-referral practices also present important and widespread conflicts of interest that have challenged government in its efforts to manage, limit, or eliminate them.

This chapter begins with a brief discussion of physician payment and facility ownership interests as parts of the broader context of medical practice. As planned by the Institute of Medicine, this study was not intended to consider recommendations on physician payment; that is a primary charge of the Medicare Payment Advisory Commission (MedPAC; a body that advises the U.S. Congress). The committee also was not constituted to consider physician ownership and self-referral issues, which would have involved the in-depth examination of a complex regulatory and commercial environment. Therefore, the discussion of these topics is only brief.

The chapter then examines industry promotional activities aimed at practicing physicians and also reviews the responses to concerns about physician financial relationships with industry from private organizations and public agencies. Because the committee considered financial relationships with industry in the context of physicians' professional obligations, the chapter includes a discussion of professional codes of conduct and statements on conflicts of interest in medical practice from professional societies. The chapter concludes with recommendations for the physician community; health care providers; and pharmaceutical, medical device, and biotechnology companies.

THE BROADER CONTEXT: PHYSICIAN PAYMENT, SELF-REFERRAL, AND CONFLICTS OF INTEREST IN MEDICAL PRACTICE

The environment of medical practice has changed significantly in recent decades. Physicians providing patient care have experienced reduced autonomy, increased administrative burdens, and declining incomes. As shown in Figure 6-1, the real income of physicians from medical practice declined about 7 percent from 1995 to 2003, a pattern that contrasts with that for other professional and technical workers. Flat or declining fees from public and private payers appear to be a major contributor to the trend (Tu and Ginsburg, 2006). Although the committee did not locate a

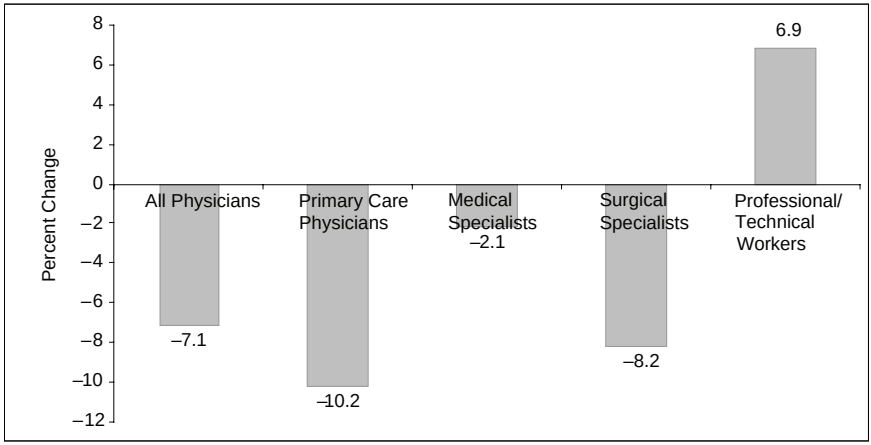

FIGURE 6-1 Percent change in average net physician income, adjusted for inflation, 1995 to 2003. Physician income data are based on reported net income from the practice of medicine (after expenses and before taxes). SOURCE: Tu and Ginsburg, 2006.

more recent analysis of trends, some data (e.g., comparisons of Bureau of Labor Statistics physician and surgeon income data for 2006 and 2007) suggest a more favorable income picture in recent years.

Physician Payment and Conflicts of Interest

Researchers and policy makers have devoted considerable attention to the day-to-day incentives for inappropriate clinical practice related to physician payment arrangements. Each major method of paying physicians has the potential to put physicians' primary interest in promoting the best interests of their patients at odds with their secondary financial interests.

Many studies have concluded that paying physicians for each service that they provide creates incentives for physicians to increase the volume of services, which also increases their income and society's spending for health care (see the reviews by CBO [1986], OTA [1986], PPRC [1987], Smith [1992], and Hsiao et al. [1993]). In addition, the appropriate pricing of specific services and categories of services is a concern (see, e.g., Ginsburg and Grossman [2005] and Bodenheimer et al. [2007]). Higher levels of reimbursement for procedures (e.g., surgeries, invasive procedures, diagnostic imaging, and chemotherapy) compared with the level of reimbursement for non-procedure-related services (e.g., history taking, medical evaluations, and counseling) have contributed to an escalation in the use of procedures and to the shift in the performance of certain lucrative procedural services

from hospitals to physicians' offices. One analysis of information from national surveys and long-term, in-depth studies of 12 local markets concluded that physicians' business practices contribute to higher costs and that "policymakers may need to revisit regulation of physicians' conflicts of interest and consider how their financial incentives could be realigned" (Pham et al., 2004, p. 70).

Payments to physicians on a capitated basis (i.e., a fixed, per person payment for a patient population) and managed care restrictions on referrals and certain services raise concerns about the underprovision of needed care (see, e.g., Hillman [1987], GAO [1995], Rodwin [1996], and Sulmasy et al. [2000]). In general, payment methods have become more complex as public and private health insurers have offered incentive payments to physicians related to quality standards, patient satisfaction, and better patient outcomes (see, e.g., Epstein et al. [2004], MedPAC [2005c], Rosenthal et al. [2007], and Nicholson et al. [2008]).

Self-Referral and Physician Ownership of Health Care Facilities

A former editor of the *New England Journal of Medicine* observed that "[p]hysicians have been conflicted about their dual roles as professionals and businessmen for millennia, but this dilemma has sharpened in recent years as income from the practice of medicine has faltered" (Kassirer, 2001, p. 159). The dilemma is particularly evident, first, in the growth of physician ownership of (or other business arrangements with) outpatient diagnostic or treatment centers and specialty hospitals to which they refer patients and, second, in the increase in expensive in-office ancillary equipment (e.g., equipment used for imaging and other diagnostic services ordered by the physician owner). As described by Pham and Ginsburg (2007)

> The allure of profitable services has led to increased physician ownership of ambulatory surgical, imaging, and endoscopy centers and other free-standing facilities such as specialty hospitals. For example, the number of cardiac and orthopedic specialty hospitals serving Medicare patients grew from twenty-one in 1998 to sixty-seven in 2003, the majority of which were for-profit and owned in part by physicians. The number of ambulatory surgery centers (ASCs) grew more than 35 percent between 2000 and 2004, with 83 percent of existing centers partly or wholly owned by physicians. In addition, physicians have brought the capacity for more diagnostic and therapeutic procedures into their practices. (p. 1591)

Physicians' ownership interests in facilities to which they refer patients constitute a conflict of interest. Their secondary interest (i.e., increased income from increased services) has the potential to bias physicians' primary interest in their patients' welfare. Such conflicts of interest may harm

patients who receive unnecessary services and may also harm society, which is burdened by excess spending on these services. In fact, some research has contradicted claims that physician ownership improves access for underserved populations (see, e.g., OIG [1989], Hillman et al. [1990], and Mitchell and Scott [1992]).

Concerns about physician self-referral have prompted the passage of complex federal legislation and the implementation of regulations (often collectively referred to as the "Stark laws," after the sponsor of relevant provisions in the Omnibus Budget Reconciliation Act of 1989 and other legislation). In general, federal law prohibits physicians from referring Medicare or Medicaid beneficiaries to entities for "designated health services" if the physicians or their immediate family members have ownership or investment interests in the entities or have compensation arrangements with the entities (42 USC 1395nn and 42 USC 1396b(s)).[1]

In 2008, the Centers for Medicare and Medicaid Services issued a new rule requiring physicians to disclose to patients the physician's ownership of or investment in hospitals (CMS, 2008). It is too early to evaluate the experience with this requirement, although the discussion reviewed in Chapter 3 suggests that the need for caution in assuming the effectiveness of disclosure alone as a safeguard against making biased recommendations. In 2009, MedPAC recommended that Congress require hospitals and other entities that bill Medicare to report physician ownership interests (direct and indirect) and that this information be posted on a public website (MedPAC, 2009). MedPAC also recommended that the secretary of the U.S. Department of Health and Human Services submit a report on the types and prevalence of financial arrangements between physicians and hospitals.

INDUSTRY PROMOTIONAL ACTIVITIES AND PRACTICING PHYSICIANS

Scope and Nature of Marketing Activities

Marketing is a major expense for pharmaceutical companies. A recent analysis estimated that pharmaceutical company expenditures for promotional activities were $57.5 billion in 2004, including $20.4 billion for

[1] "Whole" hospitals are not included under the law, which some suggest has been a factor spurring the growth of physician-owned specialty hospitals (Mitchell, 2008). The law also does not cover the purchase and use of imaging and other ancillary equipment within a physician's office. Designated health services include clinical laboratory services; inpatient and outpatient hospital services; diagnostic radiology services; radiation therapy services and supplies; durable medical equipment and supplies; prosthetics, orthotics, and prosthetic devices and supplies; home health care services; physical therapy services; outpatient prescription drugs; occupational therapy services; and parenteral and enteral nutrients, equipment, and supplies.

detailing (sales visits) by drug company representatives, $15.9 billion for drug samples, and $2.0 billion for meetings (Gagnon and Lexchin, 2008). Little information is available on the marketing of medical devices and biologics.

Pharmaceutical company representatives use a variety of interpersonal techniques, including gift giving, to establish relationships with physicians and promote their products.[2] They may calibrate their approach to their assessments of the physician's personality and intellectual style (see, e.g., Roughead et al. [1998], Fugh-Berman and Ahari [2007], and Greene [2007]). In addition, companies have information on individual physician prescribing practices that they can use to target physicians and then monitor the effects of their relationships (Steinbrook, 2006). As described in Chapter 1 and discussed further in this chapter, some of that information is compiled from physician data sold by the American Medical Association (AMA).

Companies may also use physicians as marketing agents. For example, an article in the *Wall Street Journal* reported data from a market research firm showing that in 2004 pharmaceutical companies sponsored some 237,000 meetings or talks that featured physicians and 134,000 meetings or talks conducted by sales representatives, up from about 60,000 talks of each type in 1998 (Hensley and Martinez, 2005). The same article also cited an internal study conducted by Merck that estimated that discussion groups led by physicians yield almost twice the benefit in terms of additional prescriptions as discussion groups led by sales representatives.

A specific example of the use of physicians for marketing involved a new vaccine for human papillomavirus and cervical cancer. The project signed up "hundreds of doctors and nurses . . . as unofficial spokesmen" who were trained by the pharmaceutical company and were "provided with a multimedia presentation and paid $4,500 for each 50-minute talk, delivered" at company-sponsored meals (Rosenthal, 2008, unpaged).

The scope of pharmaceutical company payments for speeches given by physicians is suggested in a report by the Vermont attorney general based on information received under the state's payment disclosure law (see Chapter 3). Between July 1, 2006, and June 30, 2007, pharmaceutical companies in that state spent almost $3,140,000 on payments to physicians and other providers; 52 percent of the payments were for speaker fees and 30 percent were for food (Sorrell, 2008). As discussed below, companies may

[2] A press release from PeopleMetrics Rx about a study of the influence of drug sales representatives on physician prescribing practices stated that the study found "that sales representatives must develop personal relationships with their physicians to achieve the highest levels of engagement" and that "emotional components such as friendship with the reps are the strongest indicators of Fully Engaged physicians [which] . . . has a positive impact on the duration and frequency of meetings and physician prescribing patterns" (*Business Wire*, 2008).

also market to community physicians through "seeding trials" of medications approved by the Food and Drug Administration.

Surveys of Physician Relationships with Industry

Surveys show that relationships with industry are common among physicians across the nation. In a national probability sample of more than 3,100 physicians, 94 percent reported that they had had some type of relationship with industry during the preceding year. These relationships were primarily the receipt of food in the workplace (83 percent) or drug samples (78 percent) (Campbell et al., 2007a). Thirty-five percent received industry reimbursement for costs associated with professional meetings or continuing medical education; and 28 percent received payments for activities such as consulting, serving on a speakers bureau, or enrolling patients in clinical trials. Cardiologists were more than twice as likely as family practitioners to receive payments, but family practitioners met more frequently with industry representatives than physicians in other specialties. Physicians in solo/dual or group practices met more frequently with representatives than physicians practicing in hospitals and clinics. In sum, relationships between physicians and industry are common and vary by specialty, practice type, and professional activities.

Another national survey of physicians also found that relationships with industry are common: 92 percent of physicians had received free drug samples; 61 percent had received meals, tickets to entertainment events, or free travel; and 12 percent had received financial incentives to participate in drug trials (KFF, 2002). The survey found that 15 percent of respondents thought that drug representatives provided "very useful" information, with another 59 percent describing the information as "somewhat useful." Only 9 percent thought that the information was "very accurate," whereas 72 percent thought that it was "somewhat accurate" (KFF, 2002).

A study of community obstetricians-gynecologists reported that most physicians believed that it was appropriate for physicians to accept drug samples (92 percent), a lunch at which information was provided (77 percent), or an anatomical model (75 percent) (Morgan et al., 2006). Just over half (53 percent) thought that it was appropriate for a physician identified as a "high prescriber" to accept a representative's invitation "to sit in" on a market research meeting as a well-paid consultant. In response to a question about whether interactions with industry should be more strictly regulated, 40 percent disagreed, 34 percent agreed, and 26 percent were neutral. As was found in a number of other studies, the respondents thought that other physicians were more likely (probably or almost surely) to be influenced by receiving a drug sample than the respondents were (38 percent for other physicians versus 33 percent for the respondents). The researchers found no

association between the responses and familiarity with the codes of conduct of professional societies.

The studies reported here and in Chapter 5 occurred before the Pharmaceutical Research and Manufacturers of America (PhRMA) revised its *Code on Interactions with Healthcare Professionals* in 2008. These revisions, which set some limits on gift giving and other relationships and which are discussed further below, took effect in January 2009. The Advanced Medical Technology Association (AdvaMed) adopted similar revisions in its *Code of Ethics on Interactions with Health Care Professionals*, effective in July 2009. Thus, it is too early to gauge the effects of these changes on physician relationships with pharmaceutical and medical device companies.

Participation of Community-Based Physicians in Clinical Trials

As mentioned in Chapter 4, physicians in private office settings are increasingly participating in clinical trials that are sponsored by industry and managed by contract research organizations or research site management organizations. The percentage of clinical trials conducted in academic health centers has decreased, and academic health centers are now in the minority among the locations for clinical trials (Klein and Fleischman, 2002). The marketing aspects of some of these trials were described above. The involvement of practicing physicians in clinical trials in the community has potential benefits. For example, their patient pool may be more representative of all patients with the condition being studied than the patient pool of academic physicians, so the results may be more generalizable. Furthermore, the recruitment of participants and the conduct of the study may be more rapid and less expensive in the community setting than in academic medical centers. In addition, such trials may be educational for the participating physicians.

Several concerns have, however, been raised about conflicts of interest in industry-sponsored trials involving community physicians. First, payments to participating physicians may provide incentives to enroll and retain patients, but they may also exceed actual expenses. In guidance provided to pharmaceutical companies, the Office of the Inspector General of the U.S. Department of Health and Human Services has cautioned against payments that exceed fair market amounts for "legitimate, reasonable, and necessary services" (OIG, 2003, p. 21). Second, practicing physicians may have a powerful influence over their patients, perhaps more so than physicians in academic centers, which have high rates of turnover of residents, fellows, and faculty and which allow investigators studying common diseases to recruit participants who are not their personal patients.

In addition, some clinical trials in community practices may be "seed-

ing" trials that companies design to change prescribing habits rather than to gather scientifically useful information (Hill et al., 2008; see also Psaty and Rennie [2006] and Sox and Rennie [2008]). As described in an analysis of documents obtained during litigation, the strategy of such trials is to "target the [clinical] trial to a select group of customers—in this case, primary care physicians; use the trial to demonstrate the value of [the drug] to these physicians; integrate the marketing division and those responsible for trial-related operations in the field with the highest level of precision; and carefully track marketing-related results, that is, rates of [product] prescriptions written by study physicians" (Hill et al., 2008, p. 253). The company in the case under litigation described the physicians as "key customers" (p. 255) and provided them with materials to market their involvement in the study. It also "hid the marketing nature of the trial from participants, physician investigators, and institutional review board members" (Hill et al., 2008, p. 251). As an additional marketing tool, companies may sometimes employ physician opinion leaders as consultants on the use of a drug under study.

A study by Andersen and colleagues (2006) found that general practitioners involved in industry-sponsored studies increased their use of the trial sponsor's drugs, which is consistent with the purpose of using the seeding strategy. Whether the increased use was medically appropriate was not evaluated, but seeding studies subvert ethical standards for research conduct and can put patients at risk.

As part of a broad policy that prohibits or limits many types of company payments to physicians and requires disclosure of other payments, Massachusetts recently issued regulations that require disclosure by companies of payments to physicians for studies "that are designed or sponsored by marketing departments of manufacturers or that are undertaken to increase sales of a particular drug, biologic or medical device" (Lopes, 2009, p. 8). Payments for scientific research need not be disclosed.

Community Versus Academic Practice Environment

Chapter 5 reported on the extensive relationships between academic physicians and industry and discussed industry promotional activities undertaken in the context of graduate and undergraduate medical education. It reported on studies that suggest that industry relationships and promotional activities (e.g., detailing visits) in both academic and general practice settings may influence physician prescribing patterns and requests for additions to hospital formularies. It also reported on studies—conducted mostly in academic settings—that indicate that the provision of free drug samples to physicians may contribute to inappropriate prescribing practices, lower

rates of use of generic and over-the-counter drugs, and increased drug costs.

Chapter 5 also noted that trainees in academic settings have ready access to the latest scientific information through faculty experts and advanced information technologies that they may use to search the medical literature; they do not require interactions with company sales representatives to obtain information on a new drug or its use. Faculty members—in addition to being in the forefront of knowledge development and evaluation in their own fields—also have ready access to the expertise of their colleagues. In contrast, community physicians have less access to such expertise, and that has been one argument in support of visits to community physicians by drug company sales representatives. Sales representatives are, however, tasked with promoting their company's products and not with providing a balanced assessment of the evidence for the use of different clinical options, including nonpharmacologic approaches.

One response to the informational needs of community physicians has been the development of accredited continuing medical education programs. Nevertheless, a recent historical review of pharmaceutical marketing and physician education suggested unintended consequences, that is, the provision of "novel sites of intersection between pharmaceutical marketing and physician education" (Podolsky and Greene, 2008, p. 833). Concern about such consequences has, in turn, produced new approaches, including the "academic detailing" programs described later in this chapter.

In research, the community practice environment is clearly different from the environment in academic medical centers and major teaching hospitals. Although the research may be reviewed in advance by an institutional review board, community physicians may receive no training in the standards of the ethical conduct of research, may have little contact with experienced clinical researchers, and may lack the knowledge needed to review contract or research descriptions provided by a company. In sum, the environment in which community physicians interact with industry may be quite different from the environment of academic physicians discussed in Chapter 5.

RESPONSES TO CONCERNS ABOUT INDUSTRY RELATIONSHIPS AND CONFLICTS OF INTEREST IN COMMUNITY PRACTICE

Responses to concerns about physician financial relationships with industry date back many years. For example, in 1972 the U.S. Congress acted to outlaw certain industry payments or other inducements to physicians. The discussion below focuses on the responses to those concerns made by professional societies, industry, and government. It does not examine responses by provider organizations, such as multispecialty group

practices or hospitals. The committee found no systematic information on the responses by such organizations but identified examples of conflict of interest or other policies that restrict certain individual or organizational relationships with industry (see, e.g., Kaiser Permanente/TPMG [2004], Vesely [2005], and Henry Ford Health System [2007]). Consistent with the emphasis on professional values in this chapter, this section begins with a review of professional society policies.

Professional Societies

Several medical professional organizations have adopted guidelines, codes, or other statements that cover physician relationships with industry, but the committee found no comprehensive overview of statements (or the absence of statements) from professional societies. A selective review of society policies suggests that statements about gifts are fairly common, whereas statements about promotional speaking, ghostwriting, and consulting arrangements are not. A number of professional groups have endorsed a charter for medical professionalism that identifies "maintaining trust by managing conflicts of interest" as 1 of 10 key responsibilities of physicians (ABIM Foundation et al., 2002, p. 245).

Box 6-1 includes excerpts from general statements by AMA and ACP on gifts from industry to physicians. The AMA statement, which was first adopted in 1990, has been endorsed or used as a model by a number of other professional societies, including the American Academy of Pediatrics (Fallat and Glover, 2007), the American College of Obstetricians and Gynecologists (Morgan et al., 2006), and the American College of Rheumatology (ACR, 2007). AMA has also made specific recommendations regarding medical device representatives. It emphasizes that information from or training by such representatives should not be a substitute for the appropriate training of physicians and should be subject to facility policies that govern the presence of such representatives (e.g., informing patients, protecting privacy, and credentialing) (AMA, 2007).

Although ACP strongly discourages the acceptance of gifts and poses some pointed questions for physicians to consider before accepting them, it acknowledges that many physicians feel more comfortable with gifts than the tone of its position statement would imply (Coyle et al., 2002a). The statement observes that "[i]deally, physicians should not accept any promotional gifts or amenities, whatever their value or utility, if they have the potential to cloud professional judgment and compromise patient care" but "[a]s a practical matter, many physicians are comfortable" accepting gifts of modest value that may enhance medical practice or knowledge (p. 398).

BOX 6-1
Excerpts from Statements on Gifts by American Medical Association and American College of Physicians

American Medical Association

Ethical Opinion E-8.061: "Ultimately, it is the responsibility of individual physicians to minimize conflicts of interest that may be at odds with the best interest of patients and to access the necessary information to inform medical recommendations. . . . (1) Any gifts accepted by physicians individually should primarily entail a benefit to patients and should not be of substantial value. Accordingly, textbooks, modest meals, and other gifts are appropriate if they serve a genuine educational function. Cash payments should not be accepted. The use of drug samples for personal or family use is permissible as long as these practices do not interfere with patient access to drug samples. . . . (2) Individual gifts of minimal value are permissible as long as the gifts are related to the physician's work (e.g., pens and notepads). . . . (7) No gifts should be accepted if there are strings attached. For example, physicians should not accept gifts if they are given in relation to the physician's prescribing practices" (AMA, 2002 [updated]).

American College of Physicians

"The acceptance by a physician of gifts, hospitality, trips, and subsidies of all types from the health care industry that might diminish, or appear to others to diminish, the objectivity of professional judgment is strongly discouraged. As documented by some studies, the acceptance of even small gifts can affect clinical judgment and heighten the perception and/or reality of a conflict of interest. Accordingly, physicians need to gauge regularly whether any gift relationship is ethically appropriate and evaluate any potential for influence on clinical judgment. In making such evaluations, it is recommended that physicians consider such questions as 1) What would the public or my patients think of this arrangement? 2) What is the purpose of the industry offer? 3) What would my colleagues think about this arrangement? 4) What would I think if my own physician accepted this offer? In all instances, it is the individual responsibility of each physician to assess any potential relationship with industry to assure that it enhances patient care and medical knowledge and does not compromise clinical judgment" (Turton and Snyder, 2007, p. 469, revising Coyle et al., 2002a).

With respect to consulting, the ACP policy also advises physicians to "guard against conflicts of interest when invited to consult or speak for pay on behalf of a company" because "[i]t is likely that a company will retain only individuals who make statements or recommendations that are favorable to its products, thus compromising the physician's scientific objectivity" (Coyle et al., 2002a, p. 399). Furthermore,

> Physicians should also be circumspect if asked to deliver educational programming developed by a medical education and communication company. Such companies, which are largely financed through the pharmaceutical industry, are for-profit developers and vendors of continuing medical education. It is important that physicians retained as lecturers in such settings control the content of the educational modules they deliver rather than allow their presentations to be scripted by the company. Lecturers should screen industry-prepared presentation aids (such as slides and reference materials) to ensure their objectivity and should accept, modify, or refuse them on that basis. Presenters using such materials should disclose their source to audience members. Paid efforts to influence the profession or public opinion about specific medical products are particularly suspect. It is unethical, for example, for physicians to accept commissions for articles, editorials, or medical journal reviews that are actually ghostwritten by industry or public relations firms in an attempt to "manage the press" about certain products or services. (Coyle et al., 2002a, p. 399)

During the course of the committee's work, the Council of Medical Specialty Societies (CMSS) initiated a project to collect best practices on disclosure and limitation of conflict of interest and develop a statement on conflict of interest (The Associated Press, 2008). A CMSS task force recently recommended elements that specialty society policies should include, and it also proposed the development by CMSS of a template for such policies. The task force recommended that societies post their policies and provide information about the financial support that they receive from industry (CMSS, 2008). The CMSS earlier adopted a consensus statement on medical ethics that, among other provisions, states that:

- Physicians should resolve conflicts of interest in a way that gives primacy to the patient's interests.
- Physicians have an ethical obligation to preserve and protect the trust bestowed on them by society (CMSS, 1999, unpaged).

Although this chapter focuses on individual physicians, professional societies as organizations may also have financial relationships with industry. Such relationships include unrestricted educational grants, income from exhibitions and meetings, industry advertisements in the journals of professional societies, and funding for the development of practice guidelines. As discussed further in Chapter 8, such relationships can constitute institutional conflicts of interest, and the committee recommends the adoption of policies on such institution-level conflicts.

The committee found little information about the positions of state medical societies on individual or organizational relationships with medical product companies. The Wisconsin Medical Society announced in 2008 that

its policy (which is not binding on physicians) is now that physicians should not accept gifts from companies whose products they prescribe to their patients. It noted that a "complete ban eases the burdens of compliance, biased decision making, and patient distrust" (WMS, 2008, unpaged).

Industry Codes and Company Actions

As mentioned above, the PhRMA *Code on Interactions with Healthcare Professionals* was revised in 2008 (and was effective in January 2009) and the AdvaMed code was also revised in 2008 (and was effective in July 2009). Some of the PhRMA code's provisions are summarized in Box 6-2. Overall, the revised code discourages noninformational physician-company relationships, such as speaker training programs at resorts and meals provided by sales representatives outside a physician's office or other medical setting. In addition, the revised code provides that the chief executive officers and compliance officers of companies certify yearly that they have a process in place to implement the code. Companies that do that will be identified on the association's website; AdvaMed has announced similar plans.

The 2008 revisions to the PhRMA code also include provisions about contracting arrangements. The document describes several factors as relevant to determining the legitimacy of such arrangement, including whether

- a written contract specifies the nature of the consulting services to be provided and the basis for payment of those services;
- a legitimate need for the consulting services has been identified in advance of requesting services and entering into arrangements with consultants;
- the criteria for selecting consultants are directly related to the identified purpose and the persons responsible for selecting the consultants have the expertise necessary to evaluate whether the particular health care professionals meet those criteria;
- the number of health care professionals retained is not greater than the number reasonably necessary to achieve the identified purpose;
- the retaining company maintains records concerning and makes appropriate use of the services provided by consultants; and
- the venue and circumstances of any meeting with consultants are conducive to the consulting services, and activities related to the services are the primary focus of the meeting; specifically, resorts are not appropriate venues (PhRMA, 2008, p. 8).

Partly in response to U.S. Department of Justice litigation and guidance from the Office of the Inspector General of the U.S. Department of Health

BOX 6-2
Summary of Selected Recent Revisions in the PhRMA *Code on Interactions with Healthcare Professionals*

Companies should not

- offer health care professionals any entertainment or recreational items or any gifts (e.g., notepads, mugs, and pens) that "do not advance disease or treatment education";
- create consulting arrangements as inducements or rewards for prescribing or recommending a particular medicine or course of treatment;
- create speaking engagements as inducements or rewards for prescribing a particular medicine or course of treatment or provide speaker payments above fair market value;
- fund continuing medical education programs as inducement to prescribe or recommend a particular medicine or course of treatment;
- directly subsidize the participation of a health care professional in such a program or in other conferences or professional meetings or create token consulting arrangements to do so indirectly; and
- directly provide meals at continuing medical education events.

Companies may, subject to certain standards,

- have sales representatives make informational visits to physicians and provide modest meals in connection with the visit;
- provide financial support to providers of continuing medical education so that they may reduce registration fees for programs;
- support professional and scientific meetings at appropriate locations in accord with the guidelines of the organizations supported;
- arrange for expert consultants on topics such as the marketplace, patient care, and products;
- sponsor speaker programs and provide training and reasonable compensation for speakers;
- provide scholarships for students and professionals to attend educational conferences; and
- provide educational and practice-related items of modest value to physicians.

and Human Services, some pharmaceutical companies have already revised their contracting practices. In addition, some individual pharmaceutical companies have announced that they will voluntarily post information about a range of payments to individual physicians. For example, Eli Lilly announced that it would create a publicly accessible registry of its payments to physicians beginning in 2009 (Lilly, 2008). Pfizer has released information about its grants and educational awards to medical, scientific, and

patient organizations and has announced that it is eliminating grants to commercial providers of continuing medial education (Pfizer, 2008).

Government Responses

Chapters 1, 3, and 5 discussed various responses by federal and state governments to concerns about financial relationships involving physicians and industry. At the state level, these responses range from laws requiring company disclosure of certain payments to physicians to laws restricting or prohibiting certain relationships. As noted above, some federal agency policies require disclosure of certain physician ownership interests in health care facilities, and MedPAC has proposed a substantial expansion of disclosure of such interests.

As discussed in Chapter 2, conflicts of interest do not necessarily involve actual undue influence, but they may. In some cases, they may be illegal. Federal law prohibits "any remuneration (including any kickback, bribe, or rebate) directly or indirectly, overtly or covertly, in cash or in kind" in return for ordering, purchasing, or referring patients for services or items covered by a federal health care program (42 USC 1320a-7b(b)). Such remuneration has sometimes been disguised as payments to physicians for education, consulting, or research.

In 2003, the Office of the Inspector General of the U.S. Department of Health and Human Services issued guidance for pharmaceutical companies on complying with federal laws and regulations. The guidance included a discussion of how marketing and other relationships with physicians may be designed to reduce the risk of violations of the antikickback laws (OIG, 2003). It advised, for example, that payments for research, consulting, and advisory services be set at fair market value. The guidance also noted that certain practices that are common in other business areas may be illegal in the context of federal health care programs.

For the most part, prosecutions under the statute have been directed at the companies that offer inducements rather than at the individual physicians who accept them. Cases typically do not go to trial but end in financial settlements and compliance and monitoring arrangements (corporate integrity agreements) of some sort. Box 6-3 summarizes a few illustrative settlements of cases that involved various types of financial relationships between companies and physicians.[3]

[3] At the state level, state attorneys general have reached settlements with companies that are similar to those reached by the U.S. Department of Justice. For example, Oregon was the lead state in a $58 million settlement that involved 30 states and a 3-year investigation of deception in the marketing of rofecoxib (Vioxx), and the state was also involved in another multistate settlement involving charges of deceptive marketing of valdecoxib (Bextra) and celecoxib (Celebrex) (Oregon DOJ, 2008a,b).

BOX 6-3
Examples of Prosecutions Involving Kickbacks to Physicians

In 1997, a physician at the Tufts University health maintenance organization reported to federal investigators that a marketer for TAP Pharmaceuticals had offered him an educational grant if he would reverse a health plan decision to list a competing drug in the plan's formulary. Investigators taped company employees offering the physician $65,000 in "education" grants that he could use for any purpose. To settle these and other charges, the company agreed to pay the government $875,000 and enter into a corporate integrity agreement (DOJ, 2001; Studdert et al., 2004).

In 2006, Medtronic agreed to pay $40 million and enter into a corporate integrity agreement to settle charges of improper payments to physicians to promote the company's spinal devices. The improper payments included payments for physicians' attendance and expenses at medical education events and payments made under the guise of consulting, fellowship, royalty, and research activities (DOJ, 2006).

In 2007, the U.S. Department of Justice announced deferred prosecution agreements with four major orthopedic device manufacturers—Zimmer, Depuy, Biomet, and Smith & Nephew—that paid $311 million to settle allegations that they used consulting agreements and other payments as illegal inducements for physicians to use their products during the period from 2002 to 2006. The companies also entered into corporate integrity agreements that would involve extensive monitoring of their consulting needs and arrangements for an 18-month period (DOJ, 2007a).

In 2008, an Arkansas neurologist settled a U.S. Department of Justice civil suit for $1.5 million and also pled guilty to accepting kickbacks—gifts, funds for phony research studies, and sham consulting agreements—from Blackstone Medical, a medical device company (Demske, 2008).

In 2008, Merck reached an agreement with the U.S. Department of Justice to pay $650 million to settle charges that it overcharged Medicaid for three popular drugs and that its sales representatives had devised a variety of illegal arrangements (e.g., payments disguised as being for training, consultation, or market research) to induce physicians to use its products. The company also agreed to a 5-year corporate integrity agreement to prevent future improper conduct (DOJ, 2008).

For the orthopedic device companies mentioned in Box 6-3, the deferred prosecution agreements with the U.S. Department of Justice had some features that are similar to those in some of the conflict of interest policies and proposals discussed in this report. One was that the companies agreed to post on their websites the names of physician consultants and the

payments made to them. In addition, new consulting agreements with physicians would require the physicians to agree to reveal the arrangement to their patients. For the 18-month period that they were in place, the deferred prosecution agreements provided that each company must undertake an assessment of its reasonable needs for educational consulting services and new product development consultants. They also provided for a federal monitor at each company to review compliance for all new and existing consulting relationships with the companies.

Academic Detailing and Other Prescriber Outreach Strategies

As one alternative to physician reliance on company sales representatives for information, "academic detailing" incorporates techniques that pharmaceutical company representatives use. Programs may use in-person visits to physicians by a clinical pharmacist or physician, provide educational materials and branded items, and offer individualized feedback on performance. The goal is to reduce inappropriate prescribing of targeted drugs, for example, inappropriate antibiotics and less effective vasodilators and analgesics. Randomized controlled trials have shown that such educational interventions are effective and have not found adverse clinical consequences (see, e.g., Soumerai and Avorn [1990], Solomon et al. [2001], van Eijk et al. [2001], and Simon et al. [2005]; but see also Lu et al. [2008]). These trials support other studies that suggest that the techniques that pharmaceutical company representatives commonly use are indeed effective in changing physician prescribing behavior.

Some states, including Pennsylvania, South Carolina, and Vermont, have initiated programs using such academic detailing. Pennsylvania's program has an operating budget of approximately $1 million per year, which funds about 1,000 detailing visits by a paid staff (Reck, 2008). Members of the U.S. Congress have proposed the creation of a federal program that would "provide grants or contracts for prescription drug education and outreach for healthcare providers and their patients" (HR 6752, July 31, 2008).

RECOMMENDATIONS

As described in this chapter, relationships between physicians in practice and drug and medical product companies are extensive and have prompted a range of responses from professional societies, government officials, and others. The environment of community medical practice presents challenges different from those posed in academic and research settings. In particular, physicians in community practice often have weaker ties with institutions than academic physicians and a greater degree of autonomy. In addition,

although Chapters 3 and 5 cite questions about the implementation of conflict of interest policies by academic institutions, these institutions are generally in a stronger position to enforce employee adherence to conflict of interest policies than professional societies are to enforce member adherence to their policies and codes of ethics.

Voluntary Action by Individual Physicians

The committee's first recommendation on conflict of interest in medical practice generally parallels that made for academic medical centers, except that it is directed in the first instance at voluntary action by individual physicians. The recommendation also calls on professional societies and health care providers (including hospitals, nursing homes, and hospices) to adopt supportive policies; but the committee believed that it was appropriate to call on physicians directly to adopt practices that are consistent with high standards of professionalism.

RECOMMENDATION 6.1 Physicians, wherever their site of clinical practice, should

- **not accept items of material value from pharmaceutical, medical device, and biotechnology companies except when a transaction involves payment at fair market value for a legitimate service;**
- **not make educational presentations or publish scientific articles that are controlled by industry or contain substantial portions written by someone who is not identified as an author or who is not properly acknowledged;**
- **not enter into consulting arrangements unless they are based on written contracts for expert services to be paid for at fair market value;**
- **not meet with pharmaceutical and medical device sales representatives except by documented appointment and at the physician's express invitation; and**
- **not accept drug samples except in specified situations for patients who lack financial access to medications.**

Professional societies should amend their policies and codes of professional conduct to support these recommendations. Health care providers should establish policies for their employees and medical staff that are consistent with these recommendations.

The teaching mission of academic medical centers—which includes helping learners at all levels to think critically and appraise the evidence and

providing appropriate role models and mentoring—provides strong arguments for the corresponding recommendations in Chapter 5. Furthermore, physicians in academic settings have ready access to objective, up-to-date information about new therapies, which is often not the case in community practice. The committee recognized the differences in academic and community environments but viewed critical thinking and the appraisal of evidence as key components of life-long learning and medical professionalism for all physicians, wherever their site of practice. The committee believes that entering into the relationships listed in Recommendation 6.1 creates unwarranted risks of compromising physician judgment and undermining public trust—risks that are not outweighed by prospective benefits for patients or society.

Evidence cited in earlier chapters and Appendix D suggests that gifts and drug samples can be influential even when their economic value is small. They primarily serve to create goodwill and a sense of reciprocity and partiality toward the marketing representatives who give them. (Gifts include meals provided to physicians and their employees as part of sales visits.) Moreover, some evidence suggests that they are associated with prescribing patterns that are inconsistent with evidence-based practice guidelines. Other evidence cited in Chapter 5 suggests that patients may have more negative attitudes toward such gifts and their potential impact on behavior than physicians do. The committee sees no convincing professional reasons to justify the acceptance of gifts or other items of material value from industry but does see the risk of bias and the loss of public trust.

To the extent that physicians outside academic institutions make educational presentations and prepare scientific publications, they should—like their counterparts who are faculty at academic institutions—refrain from participation in speakers bureaus and similar promotional activities and refuse authorship of ghostwritten articles. A physician should participate in consulting arrangements on the basis of a company's need for the physician's expertise. Such arrangements should be documented in contracts with specific tasks and deliverables and should be paid for at fair market value.

The recommendations about interactions with sales representatives are slightly different for academic and nonacademic physicians. The committee recognizes that physicians in academic settings have different responsibilities as educators and also have excellent access to information about the latest scientific and clinical developments. Physicians in busy community-based practices need objective information about new drugs and devices, as well as information that compares new drugs and devices with existing drugs and devices and that provides alternatives to drugs and devices. By making visits to physicians' offices, company representatives may provide this information in a convenient manner. In the future, however, with the

continued growth of Internet resources and the development of prescriber outreach and other educational programs, alternative sources of timely, objective, up-to-date information should become more available and readily usable.

If a physician chooses to meet with pharmaceutical and device company representatives, certain conditions should apply. Meetings should be at the invitation of the physician and by appointment and should not involve gifts, including meals provided at the physician's office. In limited cases, it may be appropriate for meetings to take place in the presence of patients (with their informed consent), primarily when representatives are providing in-service education or assistance with devices or equipment.

A related issue is drug company access to physician prescribing information. Currently, drug companies can buy coded prescribing information from pharmacy benefits programs and pharmacy chains. Companies can also purchase data from the AMA Masterfile, which links physician license numbers with their names, addresses, and phone numbers. Some physicians and others have objected to this practice (Steinbrook, 2006). In response, AMA now allows physicians who do not want their identifying information to be provided to companies to fill out a form to request that their data not be made available to company sales representatives and their supervisors (O'Reilly, 2006). (Other company personnel could still have access to the information.) It would be preferable and a lesser burden on physicians for AMA to set the default option so that identifying information would not be provided unless a physician affirmatively agrees.

As discussed in Chapter 5, the committee recognizes that access to affordable medications is a serious problem for many Americans, but it believes that reliance on drug samples is an unsatisfactory response. Samples are typically available only for newer and heavily marketed drugs, which may have no proven clinical benefits over alternatives, including less expensive equivalent drugs or generics. Although a sample may be convenient for the patient, it may not be the most appropriate medication. Many samples are provided to patients with insurance coverage and to physicians and their families, groups that do not have impaired access to medications. In such situations, the convenience of samples is outweighed by their potential to undermine evidence-based, cost-effective prescribing. For patients with chronic illnesses who lack the ability to pay for medications, a sample should be a stopgap that is accompanied by referral of the patient to a public or pharmaceutical company assistance program that can provide continuity of treatment. If physicians decide to accept drug samples, they should be given to patients who lack financial access to medications in situations in which appropriate generic alternatives are not available and the medication can be continued at little or no cost to the patient for as long as the patient needs it. The committee recognizes that physicians in

community practice may not have the option of using a centralized system of administration of drug samples, which is available in many academic medical centers. Some committee members were in favor of banning the acceptance of drug samples altogether and advocating for other mechanisms for providing access to drugs for indigent patients.

Recommendation 6.1 does not mention physician disclosure of financial relationships to patients. Patients could obtain that information, however, if the U.S. Congress were to require companies to disclose payments to physicians and to place that information on a searchable public database and also requires hospitals and other health care providers to report physician ownership interests. This option would avoid the interpersonal complexities involved with patients directly requesting or physicians directly providing such information. Patients and their families would need to be informed about the database, possibly through the use of brochures or notices in medical offices. Studies of patient use of the database would be a potential topic for the research agenda recommended in Chapter 9.

Continued Actions by Industry

The next recommendation promotes continued actions by pharmaceutical, medical device, and biotechnology companies to support the core values and missions of medicine. Some but not all of the recommended actions are covered by the revised codes issued by PhRMA (2008) and AdvaMed (2008) and by federal agency guidance to pharmaceutical companies (OIG, 2003).

RECOMMENDATION 6.2 Pharmaceutical, medical device, and biotechnology companies and their company foundations should have policies and practices against providing physicians with gifts, meals, drug samples (except for use by patients who lack financial access to medications), or other similar items of material value and against asking physicians to be authors of ghostwritten materials. Consulting arrangements should be for necessary services, documented in written contracts, and paid for at fair market value. Companies should not involve physicians and patients in marketing projects that are presented as clinical research.

The committee is encouraged that some companies have already taken steps to end company provision of certain gifts and meals and to develop new procedures for contracting with physicians for their consulting work. The revisions in the PhRMA and AdvaMed codes are also encouraging steps, especially if provisions to track and publicize adherence are meaningful. Public disclosure of commitment to the codes should put pressure on

noncomplying companies and should also reduce any competitive disadvantage to those companies that do comply. The committee would, however, like to see the provisions on gifts extended, consistent with Recommendation 6.1. The adoption of Recommendation 3.4 (which proposes that the U.S. Congress establish a program that requires companies to report their payments to physicians, researchers, and institutions) should allow monitoring of some company practices.

If the levels of adherence to the policies and practices recommended here are low, governments may enact legislation to limit physician ties to companies, as the state of Massachusetts has. In general, committee members believed that voluntary limits should be given an opportunity to work and that legislation and regulation should be held as options if they do not. The reasoning was that this approach is more likely to reinforce professional values and allow more nuanced policies and standards that take into account the possibility of unintended consequences and that create fewer administrative burdens to be developed.

Other Recommendations in This Report

Other chapters of this report also offer some recommendations that could affect community physicians. To the extent they are involved in multiple activities that require the disclosure of financial interests (Recommendation 3.3), community physicians might face more specific disclosure requests but also more consistency in requests. If federal legislation requires pharmaceutical, device, and biotechnology companies to publicly report payments to physicians (Recommendation 3.4), some community physicians might choose to forgo certain relationships with industry that they find difficult to explain and justify. Community physicians who teach medical students or residents off-site would be affected by reforms in the policies of medical schools and teaching hospitals (Recommendation 5.1). A new system of funding continuing medical education (Recommendation 5.3) could lead to higher fees for attendees and reductions in the numbers, variety, and locations of course offerings. In addition, physicians who participate in professional society or other clinical practice guideline development activities might be limited in their involvement if they had conflicts of interest, especially conflicts involving promotional activities (Recommendation 7.1).

7

Conflicts of Interest and Development of Clinical Practice Guidelines

Clinical practice guidelines lie at the intersection of medical research, education, and practice. They build on medical research and serve an educational function. In clinical care, they may influence patient and physician decisions about health care interventions, health plan coverage for medical services, and assessments of the performance of individual physicians and institutions that provide health care.

Ideally, clinical practice guidelines are based on valid scientific evidence, critical assessment of that evidence, and objective clinical judgment that relates the evidence to the needs of practitioners and patients. Arguably, the most significant problem in the development of sound clinical practice guidelines is the lack of research that can be used to guide the development of comprehensive recommendations on clinical practice. Clinical trials often exclude children, older adults, and patients with multiple or uncommon diagnoses or complex personal situations. Given the lack of evidence on many clinical topics and patient populations and the frequent lack of consistent research findings, expert judgment based on clinical experience remains a significant element in the development of evidence-based practice guidelines. As the methods manual of the American College of Cardiology and the American Heart Association states, it is not often that there is "an abundance of evidence available that leads directly to an indisputable recommendation" (ACC/AHA, 2009, p. 27).

Financial relationships with pharmaceutical, medical device, and biotechnology companies may create conflicts of interest and a risk of undue influence on judgment both for entities that sponsor the development of clinical practice guidelines and for the individuals who participate in their development. In addition to financial relationships with industry, other potential sources of bias in the development of clinical practice guidelines

include professional affiliations and practice specialization, reimbursement incentives, intellectual preconceptions and previously stated positions, and the desire for recognition and career advancement (see, e.g., Kahan et al. [1996], Ayanian et al. [1998], Murphy et al. [1998], Fitch et al. [1999], and Detsky [2006]).

This chapter begins with definitions and a brief historical overview and description of groups that develop clinical practice guidelines. It then reviews what the committee learned about the nature and the effects of sources of funding on the development of clinical practice guidelines, the financial interests of individual participants, and policies on financial relationships and conflicts of interest. A later section reviews other methods for promoting objectivity in the development of clinical practice guidelines and trust in those guidelines. The final section presents recommendations on how to reduce conflicts of interest in the development of clinical practice guidelines.

BACKGROUND AND CONTEXT

Definitions

As defined in an earlier Institute of Medicine (IOM) report, *clinical practice guidelines* are "systematically developed statements to assist practitioner and patient decisions about appropriate health care for specific clinical circumstances" (IOM, 1990, p. 8). The IOM report emphasized the role of formal evaluations of the evidence base for clinical practice guidelines and the linking of recommendations to those reviews. *Systematic reviews*, the common term used today for formal evaluations of the evidence, are highly structured assessments of the research literature that use explicit, previously defined methods and tools to identify, select, assess, and summarize research studies relevant to a technology, treatment of a clinical condition, or similar topic (see, e.g., OTA [1994] and Cochrane Collaboration [2005]). A *meta-analysis* is a quantitative summary of the data examined in a systematic review. As explained below, various groups have devised tools for assessing the extent to which a set of guidelines are based on systematic, evidence-based procedures.

Evolution of Clinical Practice Guidelines

The American College of Cardiology, the American College of Physicians, the National Institutes of Health (NIH) Consensus Development Program,[1] the U.S. Preventive Services Task Force, the Blue Cross and

[1] Since 1977, the Consensus Development Program at NIH has sponsored "an unbiased, independent, evidence-based assessment of complex medical issues" (NIH, undated). It orga-

Blue Shield Association, ECRI (now the ECRI Institute), and the RAND Corporation were, among others, leaders in devising systematic methods for assessing the evidence and developing clinical recommendations for practitioners, patients, payers, and others (see, e.g., IOM [1985, 1988] for contemporary descriptions of such activities). In 1989, the U.S. Congress created the Agency for Healthcare Policy and Research (AHCPR) and gave it responsibility for creating a public-private partnership to develop, disseminate, and evaluate clinical practice guidelines (P.L. 101-239). In 1995, the Congress came close to defunding the agency in response to lobbying by back surgeons who disagreed with the agency's guidelines for the treatment of low back pain developed by an AHCPR Patient Outcomes Research Team (Deyo et al., 1997; Gray et al., 2003; see also Clancy [2003], Gaus [2003], and Wennberg [2003]). Other government bodies charged with some aspect of technology assessment have also been defunded under circumstances that underscore the political sensitivity of this activity (for example, the National Center for Health Care Technology in 1982 and the congressional Office of Technology Assessment in 1995) (see, e.g., Bimber [1996], Rettig [1997], Eisenberg and Zarin [2002], and Keiper [2005]).

After its close call, AHCPR—rechristened the Agency for Healthcare Quality and Research (AHRQ)—withdrew from the work of developing clinical practice guidelines. Instead, the agency supports evidence-based practice centers that conduct systematic reviews that government agencies, professional societies, and other groups can request and use to develop guidelines and other recommendations. In 2008, AHRQ supported 14 such centers, 5 of which focused on assessments for the Centers for Medicare and Medicaid Services. One evidence review (performed under a grant from AHRQ) by the RAND Corporation's Evidence-Based Practice Center concluded that the quality of practice guidelines suffered as a result of the retreat of the agency from guideline development (Hasenfeld and Shekelle, 2003; see also Grilli et al. [2000]).

The U.S. Preventive Services Task Force, which was created several years before AHCPR/AHRQ but which is now part of the agency, continues to develop evidence-based guidelines for preventive services. It is currently supported by one evidence-based practice center. Other federal agencies, such as NIH and the Centers for Disease Control and Prevention, also develop practice guidelines.

To support the dissemination of the clinical practice guidelines developed and submitted by others, AHRQ sponsors the National Guideline

---

nizes conferences that are jointly sponsored and administered by one or more NIH institutes or centers and the Office of Medical Applications of Research, which is located in the Office of the Director of NIH. Other federal agencies may participate if their expertise is relevant to the topic. Currently, the Agency for Healthcare Research and Quality provides a systematic review of the conference topic from one of its Evidence-Based Practice Centers.

Clearinghouse. The guidelines posted by the clearinghouse are summarized in a common format that includes headings for information about the source(s) of funding and about financial disclosures or conflicts of interest.[2] Although the clearinghouse is the most comprehensive source of information on the funding of guideline development activities and on financial disclosures and conflicts of interest, its data have some significant limitations. The analysts who compile the guideline summaries primarily rely on source documents provided by the guideline sponsor, and those documents may be incomplete. For example, because the source documents are silent on the topic, "Not stated" entries for "financial relationships/conflict of interest" may be found in clearinghouse summaries of guidelines for groups such as the American College of Physicians and the U.S. Preventive Services Task Force. These two groups do, in fact, have a process of disclosing, evaluating, and managing conflicts of interest.[3] Given these and other limitations in the clearinghouse database, the committee used information from the database on funding sources and disclosures with caution.

The guideline initiatives described above and other initiatives have gradually but not fully replaced less rigorous guideline development efforts that lacked formal procedures, clear reporting of the authors involved with and the methods used for the systematic review of the evidence, and explicit links between the recommendations and the supporting evidence. Shortcomings in the processes for the development and reporting of clinical practice guidelines persist. These shortcomings include the incomplete disclosures of the financial relationships of the participants and the funding sources and informal procedures, which increase the opportunity for undue influence and bias (see, e.g., Shaneyfelt et al. [1999], Burgers et al. [2003], Harpole et al. [2003], Hasenfeld and Shekelle [2003], Shiffman et al. [2003], Boluyt et al. [2005], Guyatt et al. [2006], Poitras et al. [2007], Nix [2008], and Nuckols et al. [2008]).

[2] The criteria for the inclusion of a guideline in the clearinghouse relate to sponsorship, evidence of some kind of literature review, adoption of the guideline within the last 5 years, and print or online availability of the complete text of the guideline.

[3] To cite one example of how such omissions may occur, when U.S. Preventive Services Task Force guidelines are published in journals that require disclosures, they include a statement (compare, e.g., the guidelines on screening for lipid disorders in children as published in *Pediatrics* at USPSTF [2007a] and as published online at USPSTF [2007b]). In contrast, guidelines presented on the agency's website do not routinely include information about the group's conflict of interest policies and procedures or about the authors' financial relationships (see, e.g., guidelines on screening for sickle cell disease in newborns at USPSTF [2007c]). The processes for developing the guidelines were the same, but the information in the clearinghouse varies because the source documents varied in the information that they provided. A discussion of task force policies can be found online in the procedure manual, but the site does not highlight it (USPSTF, 2008).

Systematic Process for Developing Clinical Practice Guidelines

The adoption of explicit, systematic methods for reviewing evidence and developing and documenting practice guidelines is, as discussed further below, an important strategy for reducing the opportunities for bias, whether the source might be intellectual and professional preconceptions, financial interests, or something else. Table 7-1 depicts a generic process for developing evidence-based guidelines that is similar to that used by a number of government and professional societies. (Sponsor means the entity developing the guideline.)

At each step in this process, financial relationships may create conflicts of interest. Any of the responsible parties identified in Table 7-1 could have financial relationships with industry that could unduly influence recommendations—even when systematic reviews and other safeguards are employed. Thus, some groups have conflict of interest policies that apply not only to the expert panels that develop guidelines but also to some or all of the other responsible or involved parties. As described in Chapter 4, the evidence base itself can be biased to the extent that the publication of

TABLE 7-1 Basic Elements of Process for Developing Evidence-Based Practice Guidelines

Responsible Party	Activity
Sponsor	Select topic and provide financial and other resources
Sponsor	Appoint a panel to develop the guideline that balances relevant expertise and perspectives and that is subject to conflict of interest policies throughout the process
Panel	Develop a work plan and specify clinical questions and outcomes of interest
Panel or contractor	Conduct a systematic review of the relevant evidence by using standardized methods for selecting studies, analyzing and rating the evidence, identifying and evaluating benefits and harms, and presenting conclusions
Panel	Develop and agree on a draft guideline with recommendations explicitly linked to the evidence and expert judgment
Panel or sponsor	Distribute a draft for internal and external review
Reviewers	Review of guideline by external reviewers and internal reviewers (e.g., the governing board of a professional society)
Panel	Revise a draft and produce the final guideline
Sponsor or journal	Publish and disseminate the guideline
Sponsor	Monitor new research findings and determine whether a guideline should be updated

negative findings or findings unfavorable to a product have been delayed or suppressed.

Professional societies and other groups sometimes rely on evidence reviews conducted by AHRQ's Evidence-Based Practice Centers. (Professional societies and other groups can nominate topics for reviews. In late 2008, the agency's website listed 11 evidence reports on clinical topics as under development.) Others groups may use a combination of staff and expert panel members to conduct reviews. One reason for the latter course is the expense. Systematic reviews for a complex clinical topic may cost in the range of $300,000 to $350,000 or more (personal communication, Beth A. Collins Sharp, director, Evidence-Based Practice Centers Program, Agency for Healthcare Research and Quality, November 14, 2008). On the basis of the committee's review of descriptions of the systematic review process for several professional and patient advocacy groups, groups that rely on staff or volunteer experts vary considerably in the resources that they devote to such reviews, the rigor of their evidence review processes, and the products of these reviews.

Possible Benefits and Risks of Industry Involvement in Guideline Development

The committee found little systematic information about the funding of guidelines, the financial relationships of participants, or the effects of both. In developing this discussion and the recommendations in this chapter, it drew on testimony at its meeting and a convenience sample of information available on the Internet, as well as its experience and judgment.

Potential Benefits of Industry Relationships

Industry funding for the development of clinical practice guidelines may allow some groups to create guidelines on new topics when they otherwise would not. Groups that develop practice guidelines may also benefit from presentations by industry employees as part of the evidence consideration process, and industry employees may be asked to review evaluations of the evidence for their technical accuracy. Individual panel members who have financial relationships with industry often have expertise that is pertinent to the development of a guideline.

Risks of Industry Relationships

As observed above, relationships with industry and conflicts of interest in the development of clinical practice guidelines may exist at both the individual level (i.e., participants may have industry ties) and the institu-

tional level (i.e., the sponsoring group may rely on industry funding for guidelines). These relationships raise the possibility of conflicts of interest and undue influence at each step in the guidelines development process.

Selection of topics Groups that require industry funding for the development of practice guidelines may propose topics that will attract industry funding (e.g., a guideline on how to use a product but not whether it should be used). Among the topics proposed to potential funders, companies may favor topics and questions for which the evidence is most likely to support conclusions favorable to a particular company.

Review of evidence Studies examining the association between industry ties and the outcomes of systematic reviews or meta-analyses raise concerns.[4] Although these studies do not deal explicitly with the entire process of developing clinical practice guidelines, they examine a key element. In one study, industry-sponsored meta-analyses of drug trials were less transparent about the methods that they used, were much more likely than Cochrane Collaboration reviews to recommend the experimental drug without reservation, and had fewer reservations about the methodological limitations of the trials included in the analysis (Jorgensen et al., 2006).[5] All of the industry-sponsored reviews but none of the Cochrane Collaboration reviews recommended the experimental drug without reservation.

Another study examined review articles on the health effects of secondhand smoke (Barnes and Bero, 1998). Ninety-four percent of the review articles written by individuals affiliated with the tobacco industry concluded that passive smoking is not harmful to health, whereas 13 percent of the reviews written by authors without such an affiliation made that conclusion. The association between the conclusion that secondhand smoke is not harmful and an affiliation with the tobacco industry persisted even after the analysts took into account the methodological quality of the review, the year of publication, the clinical topics examined, and whether the review was subject to peer review.

[4] As described in materials prepared for the Cochrane Collaboration (2002, unpaged), "meta-analysis is a two-stage process. The first stage is the extraction of data from each individual study and the calculation of a result for that study (the 'point estimate' or 'summary statistic'), with an estimate of the chance variation we would expect with studies like that (the 'confidence interval'). The second stage involves deciding whether it is appropriate to calculate a pooled average result across studies and, if so, calculating and presenting such a result. Part of this process is to give greater weight to the results from studies which give us more information, because these are likely to be closer to the truth we are trying to estimate."

[5] The authors identified 24 Cochrane Collaboration reviews for which another meta-analysis studied the same two drugs in the same disease and was published within 2 years of the Cochrane Collaboration review. (Eight of the 24 comparison guidelines were industry supported; 9 had no declared source of support; 7 reported nonprofit support or self-funding.)

As discussed in Chapter 4, which describes additional studies, a review of meta-analyses on hypertensive drugs found that financial ties to a single pharmaceutical company were not associated with findings that favored the company but were associated with favorable conclusions (Yank et al., 2007). The authors further noted that peer reviewers and journal editors did not prevent the publication of biased conclusions.

Expert panel deliberations The committee found no systematic studies of the relationship between participant financial relationships and the content of guidelines. One study did find, however, that only 7 percent of participants in guideline development surveyed believed that their own relationships with industry influenced their recommendations, but 19 percent believed that their coauthors' recommendations were influenced by such relationships (Choudhry et al., 2002). Because more than half of the participants reported no process for disclosing financial relationships, it is not clear how well informed the respondents were about their colleagues' relationships. (The extent of the relationships identified in the study is discussed below.)

Dissemination of guidelines Even if industry support is limited to the dissemination of guidelines, such support could influence the overall strategy for dissemination in ways that unduly favor a company's product. This is one interpretation of the controversy over guidelines related to sepsis summarized in Box 7-1 below.

GROUPS THAT DEVELOP CLINICAL PRACTICE GUIDELINES

A range of public and private groups develop or collaborate in the development of clinical practice guidelines (Table 7-2). On the basis of guidelines included in the National Guideline Clearinghouse, medical specialty societies are the most common developers of the guidelines; they accounted for almost 40 percent of the guidelines in the clearinghouse database in April 2008. Professional societies report that practice guidelines are among the most valued services that they provide (see, e.g., Bennett et al. [2003], Masur [2007], and Sagsveen [2008]). Evaluations of specialty society guidelines have sometimes been critical of their lack of systematic reviews of the evidence and other characteristics (see, e.g., Grilli et al. [2000]); but the committee's review indicates that many specialty societies have taken steps to make their procedures more systematic, transparent, and evidence based by hiring knowledgeable staff and developing methods, process manuals, and policies that include conflict of interest policies and procedures. The committee found less information about the clinical guideline development-related activities of disease-specific groups.

TABLE 7-2 Number of Clinical Practice Guidelines in the National Guideline Clearinghouse by Selected Types of Sponsors, as of March 16, 2009

Type of Sponsor	Number of Guidelines
Medical specialty society (U.S. and other)	959
Professional association (U.S. and other; mostly nonphysician or mixed groups)	408
Government agency (non-U.S.)	214
Federal/state/local government agency	165
Nonprofit organization	142
Independent expert panel	97
Academic institution (U.S. and other)	98
Disease-specific society (U.S. and other)	202
Hospital/medical center (U.S. and other)	26
For-profit organization	21
Managed care organization	11
Total, all guidelines, all sponsors	2,343

NOTE: Some guidelines are developed collaboratively by more than one type of sponsor. For example, a guideline may list as developers one or more professional societies and one or more disease-specific societies. The National Guideline Clearinghouse (NGC) search option does not generate unduplicated counts by category of sponsor. The unduplicated count presented here was provided by NGC staff. Nineteen of the 26 guidelines from a hospital or medical center were submitted by a single institution.
SOURCE: Personal communication, Mary Nix, Health Scientist Administrator, National Guideline Clearinghouse, March 22, 2009.

Public agencies also develop practice guidelines. U.S. federal and state agencies and public agencies from other countries accounted for more than 500 of the guidelines in the National Guideline Clearinghouse.

Some groups involved in guideline development have sought partners. For example, the American College of Cardiology and the American Heart Association have collaborated in their guideline development program since the 1980s (ACC/AHA, 2009). Several groups are investigating an international collaboration to develop guidelines for the care of respiratory diseases (personal communication, Holger Schunemann, M.D., Ph.D., chair, Department of Clinical Epidemiology and Biostatistics, McMaster University, February 19, 2009). Compared with the complexity of simply adding individuals with different professional and other backgrounds to a guideline development panel, the management of partnerships between and among agencies tends to be more complicated because each partner usually has, for example, its own policies and procedures. Nevertheless, the

potential benefits of collaboration include the sharing of costs, broadening of the scope of the questions examined, and reductions in the number of dueling guidelines that may undermine the credibility and acceptance of recommendations.

FINANCIAL RELATIONSHIPS IN GUIDELINE DEVELOPMENT

Sources of Funding for Guidelines and Systematic Reviews

The committee found no systematic assessment of the public or private sources of funding for the development of clinical practice guidelines (see, e.g., Boyd [2008]) or systematic reviews of funding sources (Jorgensen et al., 2006). Nearly all (98 percent) of the summaries of more than 2,000 guidelines included in the National Guideline Clearinghouse as of April 21, 2008, contained a statement about the funding source, usually indicating that the group that developed the guideline had funded it (Nix, 2008). Some information is inconsistent. For example, in the summary statement for guidelines on bronchial intraepithelial neoplasia/early central airways lung cancer, the section on the source of funding states that a professional society funded it, whereas the section on financial disclosures/conflict of interest states that funding came from five pharmaceutical or biotechnology companies (NGC, 2009c; see also Kennedy et al. [2007]). Similarly, a guideline on the prevention and treatment of mucositis listed the two authoring groups as the source of funding, but the information on financial disclosures/conflicts of interest referred to unrestricted grants from unnamed companies (NGC, 2009h; see also Keefe et al. [2007]).

Some professional societies, such as the American College of Physicians, the American Academy of Neurology, the American Society of Hematology, and the American Society for Clinical Oncology, fund their guideline development programs from general revenues and, in some instances, grants from independent nonprofit organizations (ASCO, 2008; Sagsveen, 2008; personal communication, Martha Liggett, executive director, American Society of Hematology, February 24, 2008; personal communication, Vincenza Snow, director, Clinical Programs and Quality of Care, American College of Physicians, February 23, 2009). As discussed in Chapter 6, a society's general revenues may include a significant share from industry, for example, income generated by journal advertising or by pharmaceutical or device company exhibits at professional society meetings.

The committee is aware that some smaller professional societies that have sought to fund clinical guideline development and systematic reviews without industry support have found it difficult to do so (personal communication, Roger Chou, assistant professor of medicine and medical informatics and clinical epidemiology, Oregon Health Sciences University, April 2, 2008). Professional societies can, however, nominate topics for

AHRQ-supported systematic reviews, and if such a topic is selected, even a resource-limited society will have an evidence-based review with which to work.

Most, if not all, guidelines developed by government agencies in the United States (e.g., the U.S. Preventive Services Task Force) and elsewhere (e.g., the National Institute for Health and Clinical Excellence in the United Kingdom) are publicly funded. One controversial exception involving a Texas state agency is described in Box 7-1, which cites several controversies involving financial relationships in practice guidelines.

Practice guidelines are sometimes developed by ad hoc groups, which by their nature are not likely to have a well-developed infrastructure for the performance of evidence-based reviews and other activities, including procedures for identifying and managing conflicts of interest. Box 7-1 described one ad hoc initiative related to heart disease screening guidelines that provoked concerns about bias and conflict of interest.

The Cochrane Collaboration (an independent, nonprofit, international organization that produces systematic reviews, among other activities) does not allow industry funding for a review. It does, however, allow commercial contributions to a central pool of funds to be used for certain other activities, such as the translation of reviews into different languages (Cochrane Collaboration, 2006).

Although the committee found no systematic information, industry involvement in the dissemination of guidelines appears to be fairly common. For example, companies may buy copies of the journal issue in which a guideline is published. They may also develop derivative materials (e.g., summaries for lay audiences) based on the guideline. The committee was unable to systematically investigate whether dissemination activities resulted in materials that altered or elaborated on a guideline in ways that departed from the conclusions in the guideline itself.

Nature and Extent of Individual Relationships with Industry

The committee found little systematic study and documentation of financial relationships between industry and the individuals who author clinical practice guidelines. A 2002 study reported that the authors of practice guidelines had widespread financial relationships with the pharmaceutical industry (Choudhry et al., 2002).[6] Of 44 practice guidelines that Choudhry et al. initially reviewed, only 2 included disclosures of the authors' financial relationships with industry. A follow-up survey of 100 authors involved with 37 of the guidelines found that 87 percent of the authors had some

[6] The study covered guidelines that were published between 1991 and 1999, that had identifiable authors, and that had been endorsed by a "recognized" North American or European professional society.

BOX 7-1
Cases and Controversies Involving Conflicts of Interest in Guideline Development

In an investigation of pharmaceutical companies' use of educational grants (based on information provided by 23 companies), staff of the Finance Committee, U.S. Senate (2007) found that "several companies helped fund the Texas Medical Algorithm Program (TMAP) run by the Texas Department of State Health Services to develop psychiatric treatment algorithms" (p. 12). A whistleblower complaint led to the dismissal of the state employee who headed the effort and had served as a paid consultant to a company that benefited from the treatment guidelines (Waters, 2006, unpaged).

In 2006, the *Boston Globe* reported that an ad hoc group of physicians had solicited nearly $56,000 from several pharmaceutical companies to have their heart disease screening guidelines published in a supplement of a leading cardiology journal (Smith, 2006; see also, e.g., Naghavi et al. [2006]). The guidelines were subsequently criticized by an official of the National Heart, Lung, and Blood Institute, who pointed out that the supplement had been financed by a company that stood to profit from implementation of the recommendations, that the authors of the guidelines failed to reveal their relevant financial relationships with that company and others, and that the process for developing the guidelines was not evidence based or subject to rigorous review (Lauer, 2007).

Eichacker and colleagues (2006) alleged that industry funding was used to support a "three-pronged marketing strategy" to increase sales of drugs for the treatment of sepsis (p. 1640). They cited a marketing document, which is no longer available online, that described a strategy "to first raise awareness about rationing and then the disease state as a means of enhancing prospects of utilization" and then employ "highly-specific marketing initiatives to physicians and the medical trade media"; a grant would then be used to create a task force to study health care rationing in the intensive care unit; and lastly to "[r]aise awareness of severe sepsis and generate momentum towards development of treatment guidelines for the infection through establishment of the Surviving Sepsis Campaign" (AHRP, 2006, unpaged). The Infectious Diseases Society of America chose not to endorse the sepsis guidelines on the basis of concern about "the manner in which the guidelines were developed, the use of a suboptimal rating system, and their sponsorship by a drug company" (Eickhacker et al., 2006, p. 1642; see also Masur [2007]). A recent set of revisions to the guidelines reported no industry funding for guideline development meetings, and 7 of the 24 authors reported no "potential" conflicts of interest (Dellinger et al., 2008).

financial relationship or interaction with industry and that 59 percent had relationships with companies whose products were considered in the guideline. The most frequent relationship with companies involved honoraria for speaking (64 percent of the respondents, who reported an average of 7.3 companies as sources of the honoraria). Thirty-eight percent of the authors had an employee or consultant relationship with one or more companies. The majority of the authors surveyed reported no discussion of financial relationships during the guideline development process.[7]

Journal articles and other publications that contain practice guidelines vary greatly in the extent to which they include disclosures of the relevant financial relationships of the participants in the guideline development process. For the most part, disclosures emphasize financial relationships with pharmaceutical and device companies, although some describe ties to other kinds of organizations (e.g., federal research agencies and managed care organizations). Some guideline documents do not indicate whether the participants with no listed disclosures were explicitly asked to declare if they had no relevant relationships. The categorizations of the relationships are also not consistent across guideline disclosures. Some lump together relationships (e.g., research and consulting or honoraria and participation in speakers bureaus) that others report separately.

When guidelines include financial disclosure statements, the content is quite variable, as Box 7-2 illustrates. An analysis of the guideline summaries in the clearinghouse as of April 2008 found that almost half (47 percent) indicated "Not stated" under the summary heading for financial disclosure/conflict of interest (Nix, 2008). An earlier analysis found that the proportion of summaries that included some information on financial relationships or conflict of interest increased from just over 20 percent to approximately 50 percent from 1999 to 2006 (Tregear, 2007). (Most summaries in the clearinghouse are based on the source document cited for the guideline, but some reflect supplementary information provided by the groups submitting the guidelines.) In a later section, Box 7-3 provides additional examples of disclosures about conflict of interest policies.

[7] The committee also located an article reporting on a review by the Dutch Health Care Inspectorate of the influence of pharmaceutical companies in the development of practice guidelines in The Netherlands (Smulders and Thijs, 2007). As summarized in the English-language abstract, the agency concluded that "virtually all opinion leaders are financially supported by pharmaceutical companies, and therefore, potential conflicts of interest are unavoidable" (p. 2429). The agency recommended making potential conflicts more transparent by full disclosure of all relationships, especially financial relationships. It also suggested that allowing companies to review draft guidelines might reduce "undesirable initiatives" to influence guidelines, that individuals with certain kinds or levels of relationships might be precluded from participation in guidelines development, and that an independent review process might be instituted to assess guidelines for signs of interference by pharmaceutical companies.

BOX 7-2
Examples of Financial and Conflict of Interest Information Excerpted from Summaries in the National Guideline Clearinghouse

Example A
FINANCIAL DISCLOSURES/CONFLICTS OF INTEREST
Not stated. [This is the most common entry for the period from 1999 to 2006.]

Example B
FINANCIAL DISCLOSURES/CONFLICTS OF INTEREST
All participants involved in guideline development have disclosed potential conflicts of interest to their colleagues, and their potential conflicts have been documented for future reference. *They will not be published in any guideline, but kept on file for reference, if needed*. Participants have been asked to update their disclosures regularly throughout the guideline development process. [emphasis added; NGC, 2009e; see also NASS, 2008]

Example C
FINANCIAL DISCLOSURES/CONFLICTS OF INTEREST
All members of the Expert Panel complied with the Infectious Diseases Society of America (IDSA) policy on conflicts of interest, which requires disclosure of any financial or other interest that might be construed as constituting an actual, potential, or apparent conflict. Members of the Expert Panel were provided the IDSA's conflict of interest disclosure statement and were asked to identify ties to companies developing products that might be affected by promulgation of the guideline. Information was requested about employment, consultancies, stock ownership, honoraria, research funding, expert testimony, and membership on company advisory committees. The Panel made decisions on a case-by-case basis as to whether an individual's role should be limited as a result of a conflict. No limiting conflicts were identified.

Potential Conflicts of Interest: L.A.P. has served as a speaker and consultant to Schering-Plough and Pfizer. P.G.P. has received grant support from Schering-Plough, Pfizer, Merck, and Astellas; has been an ad hoc consultant for Pfizer; and has been a speaker for Pfizer and Astellas. C.A.K. has received research grants from Merck, Astellas, and Schering-Plough and serves on the speakers bureau for Merck, Astellas, Pfizer, and Schering-Plough. All other authors: no conflicts. [NGC, 2009d; see also Chapman et al. 2008]

Indirect evidence for widespread relationships with companies is presented in a study of participants involved with the development of the *Diagnostic and Statistical Manual of Mental Disorders* (Cosgrove et al., 2006). These diagnostic criteria, like practice guidelines, are based on expert reviews of the relevant evidence. (An AHRQ-funded study on conflicts of interest in commercial drug compendia should be published soon. Many

health plans, including Medicare, use evidence summarized in compendia as a basis for payment and coverage decisions.)

The committee also found a few assessments of the adequacy of disclosures in studies that have applied the standardized evaluation tool AGREE (Appraisal of Guidelines Research and Evaluation), which is further described below. One of the evaluation criteria (Item 23) is whether a guideline document includes information about participant conflicts of interest. Another criterion (Item 22) is whether the guideline is editorially independent from the funding source. Studies have found shortcomings in reporting on conflicts of interest by participants and editorial independence in a wide array of clinical practice guidelines, including guidelines on stroke rehabilitation (Hurdowar et al., 2007), occupational medicine (Cates et al., 2006), pediatrics (Boluyt et al., 2005), lung cancer (Harpole et al., 2003), low back pain (Arnau et al., 2006), and nonsteroidal anti-inflammatory drug and acetaminophen treatment of osteoarthritis of the hip or knee (Wegman et al., 2004). It is not clear whether a lack of disclosure was related to the policies of the group developing the guidelines (e.g., no policy on disclosure or disclosures were not revealed) or the policies of particular journals (e.g., no request for disclosure). A study of 191 guidelines published in six leading journals in 1979, 1984, 1989, 1994, and 1999 found reporting of conflicts of interest only in the most recent year (1999) and then for only 7 of the 40 guidelines and 18 authors for that year (Papanikolaou et al., 2001). Although all the disclosures were in journals that had disclosure policies, only 4 percent of the articles in those journals included disclosures.

Consequences of Financial Relationships

The committee found no systematic studies that investigated the association between the funding source and the development process or the content of the clinical practice guidelines. As illustrated in Box 7-2, it did find cases that raised concerns about the influence of industry funding.

The committee also found no systematic studies of the relationship between participant financial relationships and the content of the guidelines.[8] As described above, a study by Choudhry and colleagues (2002) found that

[8] In a possibly relevant study of a different kind of panel, Lurie and colleagues (2006) examined the financial relationships and decisions reached in 221 meetings of 16 advisory committees of the Food and Drug Administration. They reported that in nearly three-quarters (73 percent) of the meetings at least one committee member had a financial link to the maker of a drug being considered by the committee or had a link to a competitor company. Overall, approximately one-quarter (28 percent) of the members reported conflicts. They concluded, "A weak relationship between certain types of conflicts and voting behaviors was detected, but excluding advisory committee members and voting consultants with conflicts would not have altered the overall vote outcome at any meeting studied" (p. 1921).

only 7 percent of participants in guideline development surveyed in their study believed that their own relationships with industry influenced their recommendations, but 19 percent felt that their coauthors' recommendations were influenced by such relationships. Also as described above, studies examining industry ties and the outcomes of systematic reviews raise concerns about undue influence.

A few case studies examine conflicts of interest for specific guidelines or guideline development programs. For example, in 2006, 14 of 16 members of a group that worked on the development of guidelines for the treatment of anemia in patients with chronic kidney disease received consultant fees, speaking fees, research funds, or some combination thereof from at least one company that could be affected by the guidelines (Coyne, 2007). The principal funder of the guidelines was a company that would be affected by the guidelines, and the chair and cochair of the work group had financial relationships with that company (KDOQI, 2007). The work group recommended that the dosage of a drug made by the company be raised, which could have substantially increased costs to the Medicare program. By coincidence, the guidelines were announced at the same time that research that showed adverse patient outcomes associated with the approach recommended by the guidelines was published. The lead investigator of the research allegedly informed the guideline development work group that the study in question had been terminated early, and he advised that they wait for the results before issuing the new guidelines. The group, however, chose not to wait. The entity that sponsored the work group recently described changes in its conflict of interest policies, which it described as providing "an even higher level of transparency" by providing that financial disclosures would be discussed at the meetings of guideline development groups, that those reviewing the evidence would be "empowered to assure that all guideline recommendations are supported by the evidence," that the organization's compliance officer would monitor guideline development activities and report to the organization's board on issues relating to conflict, and that no future guideline could be funded by a single industry sponsor (NKF, 2007).

POLICIES ON CONFLICTS OF INTEREST IN CLINICAL PRACTICE GUIDELINE DEVELOPMENT

Characteristics of Policies

The committee examined a convenience sample of conflict of interest policies identified through the National Guideline Clearinghouse, presentations at committee public meetings, organizational websites, documents describing guidelines, assessments of specific guidelines, other publications,

and discussions with staff or members of organizations involved with guideline development. It found no systematic information on the conflict of interest policies of groups that develop clinical practice guidelines. Reviews by Boyd and Bero (2006) and Boyd (2008) likewise found no systematic descriptions or assessments of these policies.

The availability, representativeness, and quality of the available information are limited in several important ways. As noted above, even if the developers of guidelines have conflict of interest policies, they may not refer to them in individual guideline documents. This in turn means that the summaries in the National Guideline Clearinghouse are likely to have no information either. A number of groups have recently revised aspects of their policies, and the committee is aware of other groups that are considering changes. In some cases, these changes may not be reflected on websites or in publications.

From the policies examined, the committee identified several variations in organization conflict of interest policies and procedures. They vary in the

- information required for disclosure, including how detailed the information disclosed must be, how often disclosure is requested, and whether a panel member needs to explicitly state that he or she has no relationships to disclose;
- management of disclosed information, including who reviews it and whether other panel members are told of conflicts;
- procedures for managing the relationships disclosed, including limitations of participation by members with conflicts (such as serving as chair or cochair or voting);
- provisions for public disclosure of conflict of interest policies, funding sources, and individual financial relationships;
- procedures for managing relationships with companies that provide funding for guidelines development; and
- assignment of explicit responsibility for monitoring whether institutional policies are followed.

The frequent lack of transparency of conflict of interest policies limits the ability of guideline readers to consider financial relationships and conflicts of interest as part of their assessment of the credibility of a set of guidelines. To give a sense of what readers of guidelines may encounter, Box 7-3 includes additional examples of the range of summary statements in the National Guideline Clearinghouse. (See also Box 7-2.)

The committee found few descriptions of the policies used to manage the relationship between guideline developers and industry for groups that accept industry funding for guideline development. One exception is the

BOX 7-3
Examples of Conflict of Interest Policy Descriptions Excerpted from Summaries in the National Guideline Clearinghouse

Example A
FINANCIAL DISCLOSURES/CONFLICTS OF INTEREST
Not stated. [This is the most common entry for the period from 1999 to 2006.]

Example B
FINANCIAL DISCLOSURES/CONFLICTS OF INTEREST
To assure the integrity of the Advisory Committee on Immunization Practices (ACIP), the U.S. Department of Health and Human Services has taken steps to assure that there is technical compliance with ethics statutes and regulations regarding financial conflicts of interest. Concerns regarding the potential for the appearance of a conflict are addressed, or avoided altogether, through both pre- and postappointment considerations. Individuals with particular vaccine-related interests will not be considered for appointment to the committee. Potential nominees are screened for conflicts of interest, and if any are found, they are asked to divest or forgo certain vaccine-related activities. In addition, at the beginning of each ACIP meeting, each member is asked to declare his or her conflicts. Members with conflicts are not permitted to vote if a conflict involves the vaccine or biologic being voted upon. [NGC, 2009g; see also ACIP, 2007]

Example C
FINANCIAL DISCLOSURES/CONFLICTS OF INTEREST
The American Academy of Neurology (AAN) is committed to producing independent, critical and truthful clinical practice guidelines (CPGs). Significant efforts are made to minimize the potential for conflicts of interest to influence the recommendations of this CPG. To the extent possible, the AAN keeps separate those who have a financial stake in the success or failure of the products appraised in the CPGs and the developers of the guidelines. Conflict of interest forms were

American College of Chest Physicians, whose policies are summarized in Box 7-4.

Effectiveness of Policies

The committee identified no evaluations of the impact of conflict of interest policies on the content of guidelines or other outcomes. The review by Boyd and Bero (2006) also found no rigorous assessments of conflict of interest policies for guideline development and no evaluations of different strategies for implementing or enforcing them.

obtained from all authors and reviewed by an oversight committee prior to project initiation. AAN limits the participation of authors with substantial conflicts of interest. The AAN forbids commercial participation in, or funding of, guideline projects. Drafts of the guideline have been reviewed by at least three AAN committees, a network of neurologists, Neurology peer reviewers, and representatives from related fields. The AAN Guideline Author Conflict of Interest Policy can be viewed at www.aan.com. With regards to this specific report, all authors have stated that they have nothing to disclose. One of the authors performs epidural steroid injections. [NGC, 2009b; see also Armon et al., 2007]

Example D

FINANCIAL DISCLOSURES/CONFLICTS OF INTEREST

Standards and guidelines are to insure that individuals participating in professional activities are aware of author relationships with commercial companies that could potentially affect the information presented. The American Thyroid Association has endorsed the requirement that authors disclose any significant financial interest or affiliations they may have with the manufacturers of products or devices that may be discussed in the development of guidelines. In compliance with this policy, a superscript number placed by the name of an author denotes an author who has indicated an affiliation with organizations which have interests related to the content of these guidelines. The intent of this policy is to openly identify potential conflicts of interest so that physicians may form their own judgments about the guidelines with full disclosure of the facts; it remains for the audience to determine whether an author's outside interest may reflect a possible bias in either the exposition or the conclusions presented. [NGC, 2009f; see also Cooper et al., 2006a]

NOTE: As explained in the text of this chapter, the documents on which guideline summaries are based may not include references to organizational policies that have governed the development of the guideline. Thus, a "Not stated" response does not necessarily indicate that a group has no policy.

Other Strategies to Limit Bias in the Development of Clinical Practice Guidelines

Those committed to the development and implementation of sound, credible, and useful guidelines have devised a number of methods and tools that can be used to support the creation of such guidelines. Several are listed in Box 7-5, roughly according to the step in the process of guideline development described in Table 7-1. Arguably, the most important steps are the conduct of a systematic review of the evidence and the linking of recommendations to the evidence in an explicit fashion. The strategies—and continuing areas of debate and methodological refinement—are described in depth elsewhere (see, e.g., Higgins and Green [2008] and IOM [2008]).

BOX 7-4
Policies of American College of Chest Physicians on Industry Funding of Guideline Development

- Fund development activities are undertaken by the organization's executive office without the involvement or knowledge by the organizational unit responsible for guideline development, and each guideline ideally is either self-funded or funded by at least three to five outside sources.
- Names of sponsoring companies are not revealed to staff, society members, and other participants in guideline development until the information is disclosed in the final publication.
- Sponsors do not nominate topics, participate in meetings, or review drafts. They see the guideline only upon publication.
- The organization does not inform sponsors of the participants involved in developing a guideline, the specific questions investigated, the methodologists or evidence-based practice center involved in the evidence review, the reviewers, or meeting times or places.
- Guidelines refer to pharmaceuticals only by their generic names and not by their brand names.

SOURCE: Baumann et al., 2007; Lever and Lewis, 2008.

In general, they reinforce conflict of interest policies by limiting the opportunity for secondary financial interests to exert undue influence on the primary interest of developing sound guidelines.

Unfortunately, as Steinberg and Luce (2005) have observed, rigorous methods for clinical practice guideline development and reviews of the clinical evidence are not applied consistently, and the conclusions of evidence reviews are not always interpreted appropriately. Furthermore, given that the evidence base is weak in many areas, they advise, "physicians, policymakers, and others acting on the basis of judgments, recommendations, or measures . . . should not blindly assume that the label [evidence-based] truly applies" (p. 91).

As noted earlier, in addition to developing methods to limit bias, individuals and groups have been developing tools for standardizing the presentation of guidelines and assessing the quality of guidelines across several domains (see, e.g., IOM [1992], the AGREE Collaboration [2003], and Shiffman et al. [2003]). Methodologists have also developed tools that can be used to assess the quality of systematic reviews (Shea et al., 2007; see also Oxman et al. [2006a]). The 23-item AGREE instrument, which was developed by experts from 13 countries with funding from the European Union, includes two elements that relate to conflict of interest, specifically, that the "guideline is editorially independent from the funding

BOX 7-5
Other Strategies for Limiting Bias in Clinical Practice Guideline Development

Using an explicit process to select topics for clinical practice guideline development. Various groups and individuals have recommended a formal process and the use of explicit criteria for the selection of topics for guideline development (see, e.g., Battista and Hodge [1995], IOM [1995], and Oxman et al. [2006a]). Although the primary rationale is to use limited resources to evaluate areas that offer the greatest potential to improve the quality or effectiveness of health care, another potential benefit is a reduction in the opportunity for financial relationships and other sources of bias to influence the selection of topics.

Creating a diverse expert panel. The inclusion of individuals with a range of relevant professional and other backgrounds on guideline development panels can help check financial, professional, and other sources of bias; promote the fuller consideration of potential outcomes, relevant evidence, and aspects of implementation; and help win broader acceptance by professionals, consumers or patients, health care plans, and others who play roles in the successful implementation of guidelines (see, e.g., IOM [1990, 1992, 2008] and AGREE Collaboration [2003]).

Systematically reviewing relevant evidence. As summarized by Higgins and Green (2008, Section 1.2.2) for the Cochrane Collaboration, key elements of this critical step include

- "a clearly stated set of objectives with pre-defined eligibility criteria for studies;
- an explicit, reproducible methodology;
- a systematic search that attempts to identify all studies that would meet the eligibility criteria;
- an assessment of the validity of the findings of the included studies, for example, through the assessment of risk of bias; and
- a systematic presentation, and synthesis, of the characteristics and findings of the included studies."

Using systematic procedures to evaluate the evidence, employing expert judgment, and linking recommendations to the evidence. Methodologists have developed and tested formal processes for developing consensus and otherwise structuring the expert judgment process (see, e.g., Fink et al. [1984], Murphy et al. [1998], Verkerk et al. [2006], and Renfrew et al. [2008]). In addition, considerable effort has been invested in developing and testing explicit methods for reporting and rating the evidence relevant to guidelines and for rating the strength of the recommendations (see, e.g., Guyatt et al. [1995], Lohr [2004], and Schünemann et al. [2006], and Schünemann [2008]).

Obtaining expert reviews. An independent, expert review of the guidelines and related documents is an important tool that can be used to improve the identification, evaluation, and use of the evidence. The process used to select expert reviewers should explicitly identify and assess reviewer ties with potentially affected companies.

body" (Item 22) and that "[c]onflicts of interest of guideline development members have been recorded" (Item 23). In addition, the Conference on Guideline Standardization (COG) proposed a somewhat similar 18-item checklist for reporting (documenting) guidelines (Shiffman et al., 2003). The COG list includes the identification of the funding source or sponsor, its role in developing or reporting the guideline, and the disclosure of conflicts of interest.

These and other instruments are not intended to be used to assess the full substance of the guidelines. In and of themselves, they will not identify, for example, whether key evidence has been overlooked or incorrectly assessed, whether relevant benefits or harms have been ignored or improperly weighed, or whether critical barriers to implementation have been missed. Notwithstanding some shortcomings of guideline assessment tools, their development and application underscore that it is important for documents containing clinical practice guidelines to provide potential users of the guidelines with informative descriptions of the development process, the evidence base, the participants, and the applicable conflict of interest policies. When users of guidelines confront guidelines that lack such descriptions, they would be prudent to treat the guidelines with caution and search for other guidelines that provide appropriate documentation.

Even when the developers of clinical practice guidelines use sound methods, they are often limited by shortcomings in the evidence base. A review of the guidelines in the National Guideline Clearinghouse reveals recommendation after recommendation that is supported by weak, mixed, or no evidence. Both to support the development of practice guidelines and for other purposes, many groups in the United States and elsewhere have called for greatly increased public investments in comparative effectiveness research and analysis for at least two decades (for a small sampling, see IOM [1985, 2007, 2008], OTA [1994], CBO [2007], and MedPAC [2007]). At the end of the next section, the committee endorses the recommendations for such investments that another IOM committee made recently. Overall, the combination of a better evidence base for clinical practice guidelines and better tools for assessing that evidence not only strengthens the usefulness of practice guidelines but also reduces the potential for conflicts of interest to bias guidelines.

RECOMMENDATIONS

Given the important role that clinical practice guidelines play in many aspects of health care, it is important that these guidelines be free of industry influence and be viewed by clinicians, policy makers, patients, and others as objective and trustworthy. The committee found substantial variation in the extent to which different groups disclosed their conflict of interest

policies and the financial ties to industry of the sponsoring group and the members of the guideline panel. It also found little systematic descriptions or assessments in the literature. On the basis of its judgment and experience (including experience with conflicting guidelines and guidelines not based on formal reviews of the evidence), the committee believes that the risk of undue industry influence on clinical practice guidelines is significant, and that risk justifies that strong steps be taken to strengthen conflict of interest policies governing the development of guidelines. Recommendation 7.1 proposes several such steps.

RECOMMENDATION 7.1 Groups that develop clinical practice guidelines should generally exclude as panel members individuals with conflicts of interest and should not accept direct funding for clinical practice guideline development from medical product companies or company foundations. Groups should publicly disclose with each guideline their conflict of interest policies and procedures and the sources and amounts of indirect or direct funding received for development of the guideline. In the exceptional situation in which avoidance of panel members with conflicts of interest is impossible because of the critical need for their expertise, then groups should

- **publicly document that they made a good-faith effort to find experts without conflicts of interest by issuing a public call for members and other recruitment measures;**
- **appoint a chair without a conflict of interest;**
- **limit members with conflicting interests to a distinct minority of the panel;**
- **exclude individuals who have a fiduciary or promotional relationship with a company that makes a product that may be affected by the guidelines;**
- **exclude panel members with conflicts from deliberating, drafting, or voting on specific recommendations; and**
- **publicly disclose the relevant conflicts of interest of panel members.**

Transparency is one key element of Recommendation 7.1. Groups should disclose their conflict of interest policies and their process for seeking members without conflicts of interest and its results. The disclosure of the relevant financial interests of members of guideline development panels should be sufficiently specific and comprehensive that it helps others judge the severity of the conflicts of interest, including allowing the identification of fiduciary interests (e.g., membership on company boards) and promotional relationships (e.g., participation in industry speakers bureaus).

Groups that develop guidelines should also disclose the sources and the amounts of funding provided for guideline development, including unrestricted company grants. Some committee members also wanted groups that develop guidelines to report publicly all their sources, amounts, and purposes of funding because industry contributions to general revenues (e.g., from journal advertising or unrestricted grants) could also create undue influence. The committee did not reach a consensus on this point. Other committee members were also concerned about the overall reliance of some professional and patient groups on industry funding, but they believed that this reporting of all sources and purposes of funding is not necessary, provided that groups developing guidelines adopt and implement rigorous evidence-based procedures, report indirect and direct funding sources for each guideline, and institute the conflict of interest policies and procedures recommended in this report. Another safeguard would be the continued development of processes for rating guidelines development processes, as described above. Moreover, if the U.S. Congress requires companies to report payments not only to individuals but also to a range of medical organizations, that information, in combination with the annual reports that many professional society and patient groups issue, should allow the calculation of industry funding as a share of total revenues.

Transparency also involves the inclusion of the specified information with each guideline that a group sponsors. Preferably, the information would accompany the written text, but it could—particularly if it is very lengthy—be provided by an Internet link that is maintained through the life of the guideline.

In addition to expanded disclosure about funding, the committee recommends an end to direct industry funding of clinical practice guidelines. It recognizes that this step might have the undesirable effect of reducing the involvement of professional societies in guideline development but believes that it is necessary to avoid the conflicts that come from industry financing. It is also likely that an increase in public support for systematic reviews of the evidence would buffer such effects because these reviews are an expensive part of the process of developing evidence-based guidelines. Professional societies and other groups with a shared interest in certain clinical problems could also collaborate on the development of guidelines and spread the costs. In addition, a pooling mechanism might be created—as has been suggested by some for continuing medical education—to support indirect industry funding of the development of clinical guidelines in certain broad categories.

Another important step is to exclude or substantially limit the participation of individuals with conflicts of interest on panels that develop clinical practice guidelines. As more academic institutions and other groups as well as individual professionals take the steps recommended in Chapters 5

and 6 of this report, it should be easier to find individuals who are free of conflicts of interest involving promotional relationships (e.g., participation in speakers bureaus). If groups conclude that participants with conflicts of interest are essential to provide the necessary expertise, they should demonstrate to the public that they have made a good faith but unsuccessful effort to find individuals with the required expertise and without conflicts of interest. They should also preclude individuals with conflicts of interest from chairing guideline development panels, restrict the number of individuals with conflicts of interest on panels to a distinct minority (e.g., to 25 to 30 percent of the membership), and prohibit members with conflicts of interest from drafting and deciding specific recommendations.

In addition to actions by the institutions directly involved in the development of guidelines, organizations with an interest in unbiased clinical practice guidelines can create incentives for groups that develop guidelines to adopt the recommendations presented in this report. The committee understands that the National Guideline Clearinghouse will be phasing in a requirement for the disclosure of conflicts of interest, but the committee recommends that it extend the requirement to include the disclosure of funding and policy information, consistent with Recommendation 7.1. It would also be desirable for the clearinghouse or some other entity to begin substantive assessments of the quality of clinical practice guidelines.

RECOMMENDATION 7.2 Accrediting and certification bodies, health insurers, public agencies, and other similar organizations should encourage institutions that develop clinical practice guidelines to adopt conflict of interest policies consistent with the recommendations in this report. Three desirable steps are for

- **journals to require that all clinical practice guidelines accepted for publication describe (or provide an Internet link to) the developer's conflict of interest policies, the sources and amounts of funding for the guideline, and the relevant financial interests of guideline panel members, if any;**
- **the National Guideline Clearinghouse to require that all clinical practice guidelines accepted for posting describe (or provide an Internet link to) the developer's conflict of interest policies, the sources and amounts of funding for development of the guideline, and the relevant financial interests of guideline panel members, if any; and**
- **accrediting and certification organizations, public and private health plans, and similar groups to avoid using clinical practice guidelines for performance measures, coverage decisions, and similar purposes if the guideline developers do not follow the practices recommended in this report.**

The committee expects that the adoption of the committee's recommendations will reduce the probability of undue influence from industry funding and may also reduce the number of conflicting and competing clinical practice guidelines. Some groups that have operated with undisclosed industry support or that have been unwilling to disclose the financial relationships of guideline development panel members may remove themselves from the guideline development process. Other groups may collaborate to share the costs of developing guidelines on topics of common interest.

Although the committee believes that an expanded role for public-sector sponsorship of the development of systematic reviews and clinical practice guidelines would be desirable, an examination of this issue is beyond its scope. The committee endorses the recommendation in a recent IOM report for expanded federal support for assessments of the effectiveness of clinical services (IOM, 2008). That report called for the U.S. Congress to direct the U.S. Department of Health and Human Services to designate a single entity with the responsibility and capacity to "to ensure production of credible, unbiased information about what is known and not known about clinical effectiveness" (p. 171). That entity would establish priorities for and manage the development of systematic reviews of clinical effectiveness, develop standards for such reviews and for clinical guidelines, and address conflicting guidelines. The report also recommended that accreditation organizations and other groups preferentially use guidelines developed by using the standards described in the report. In addition, it recommended that guideline development panels minimize bias by including a balance of competing interests, prohibit voting by participants with conflicts of interest, and publish conflicts that have been disclosed.

Other Relevant Recommendations in This Report

In addition to the two recommendations in this chapter, recommendations elsewhere in this report are relevant to institutions that develop clinical practice guidelines. Consensus standards on disclosure elements and procedures would make disclosures more informative as well as less burdensome for those making disclosures to multiple institutions (Recommendation 3.2). A national system for public reporting by companies of their payments to individuals and organizations would allow the easier verification of certain disclosures (Recommendation 3.4). Limitations on certain industry ties and practices (e.g., the receipt of gifts and participation in speakers bureaus) should reduce conflicts of interest among the pool of experts considered for participation in clinical practice guideline development (Recommendations 5.1, 6.1, and 6.2).

The adoption of explicit policies and procedures on institutional conflict

of interest would challenge professional societies, patient advocacy groups, and other entities that develop clinical practice guidelines to confront the scope and appropriateness of their financial ties with industry, eliminate questionable ties, and prudently manage others (Recommendation 8.1). The next chapter discusses conflicts of interest at the level of institutions.

8

Institutional Conflicts of Interest

Financial relationships with industry exist at the institutional level as well as the individual level and may create conflicts of interest for academic medical centers, professional societies, and other institutions that carry out medical research, medical education, clinical care, or practice guideline development. Some of these relationships may generate significant benefits to an institution's primary missions. For example, gifts to endow named professorships or fund the construction of research facilities support the core teaching and research missions of academic medical centers. The committee heard testimony that new kinds of institutional relationships between academia and industry—beyond relationships involving individual faculty members—could promote the translation of basic discoveries into new therapies and thereby benefit society (Benz, 2008; Moses, 2008). The question for institutions as well as individuals is whether a relationship with industry can be maintained in a way that achieves the desired benefits but avoids the risks of undue influence on decision making and the loss of public trust.

Although several cases reported by the news media have called attention to institutional conflicts of interest in medicine, institutional conflicts of interest have generally received less attention than individual conflicts of interest. Institutional conflicts of interest often involve the financial interests of both the institution and its senior officials (Box 8-1).

The risks to core missions posed by institutional conflicts of interest can be as serious as those created by individual conflicts. Moreover, if institutions do not prudently manage relationships with industry and are exposed to public criticism for inadequately or improperly managing conflicts, the work of many individual researchers, educators, and clinicians associated

BOX 8-1
Cases and Controversies Involving Institutional Conflicts of Interest

After the 1999 death of Jesse Gelsinger during a clinical trial involving a gene transfer intervention conducted by a University of Pennsylvania research institute, various investigations raised questions about the university's oversight of the study and the research institute (Stolberg, 2000; Steinbrook, 2008c). The university and several past and present officials had financial interests in the biotechnology company that developed the intervention. The company contributed $25 million to the research institute's annual budget and had exclusive rights to develop products emerging from the trial and related research. In addition, the director of the institute, who was also the lead researcher, had founded the company and maintained a financial interest in it.

In 2005, reporters revealed that the Cleveland Clinic and its chief executive officer had undisclosed financial interests in a medical device firm (Armstrong, 2005). The firm's heart surgery device was used at the hospital and was promoted by its surgeons. Patients were not informed of the conflicts of interest. The board of the Cleveland Clinic subsequently adopted new policies on institutional conflict of interest.

Amgen, the manufacturer of epoetin, a drug that increases hemoglobin levels, was the founding and primary sponsor of the Kidney and Dialysis Outcomes Quality Initiative carried out by the National Kidney Foundation (Coyne, 2007; see also Chapter 7). This project issued practice guidelines recommending an increase in the target hemoglobin level for patients with chronic kidney disease, which would entail the use of higher doses of epoetin and increased sales of the sponsor's product.

In 2008, the chair of the Psychiatry Department at Emory University resigned that position after congressional investigators reported that he had failed to disclose the receipt of substantial consulting payments from pharmaceutical companies, in violation of university and federal government rules, and had also failed to comply with an agreement with the university that he limit such payments. One of the documents cited was a letter he sent to a university official pointing out that his multiple ties to pharmaceutical companies had benefited the university by attracting company funding for department career awards, an endowed chair, and other gifts (Harris, 2008).

with the institution may unfairly be called into question, even though they were not involved in the conduct that was criticized.

This chapter begins by defining institutional conflicts of interest and describing what has been documented about the extent of such conflicts. The discussion then reviews responses to institutional conflicts of interest

and examines some of the challenges in managing such conflicts. The chapter concludes with recommendations, including a recommendation that the National Institutes of Health (NIH) require its grantees to adopt and apply policies on institutional conflicts of interest.

WHAT ARE INSTITUTIONAL CONFLICTS OF INTEREST?

Institutional conflicts of interest arise when an institution's own financial interests or those of its senior officials pose risks of undue influence on decisions involving the institution's primary interests. For academic institutions, such risks often involve the conduct of research within the institution that could affect the value of the institution's patents or its equity positions or options in biotechnology, pharmaceutical, or medical device companies. Conflicts of interest may also arise when institutions seek and receive gifts or grants from companies, for example, a gift of an endowed university chair or a grant for a professional society to develop a clinical practice guideline.

In addition, institutional conflicts of interest exist when senior officials who act on behalf of the institution have personal financial interests that may be affected by their administrative decisions. For instance, a department chair or dean who has a major equity holding in a medical device company could make decisions about faculty appointments and promotions or assignment of office or laboratory space in ways that favor the interests of the company but compromise the overall research, educational, or clinical mission of the institution. Similarly, a hospital official with such a holding would be at risk of undue influence in making decisions about the use of the company's products for patient care. In situations like these, an individual's financial relationship also implicates the institution's interests.

As emphasized in Chapter 2, conflicts of interest are defined in terms of the risk of undue influence and not actual bias or misconduct. Whether they are at the individual or the institutional level, conflict of interest policies seek to prevent compromised decision making rather than to try to remedy its consequences.

Institutional interests can be evaluated for the likelihood of undue influence and the seriousness of potential harms in ways analogous to those applicable to individual conflicts (see Chapter 2). Thus, assessments would consider the nature of the primary interest, the value and scope of the secondary interest, the extent of institutional accountability and discretion involving decisions about the primary interest at stake, and the seriousness of potential harms in relation to potential benefits (see also Emanuel and Steiner [1995]).

EXTENT OF INSTITUTIONAL RELATIONSHIPS WITH INDUSTRY

Because institutional conflicts of interest have not received as much attention as individual conflicts of interest, there is less evidence about their characteristics or impacts. The committee found little comprehensive information about the scope and nature of the ties of academic medical centers, professional societies, patient advocacy groups, and other institutions to pharmaceutical, medical device, and biotechnology companies. Such ties may involve various kinds of payments and gifts to an institution, institutional ownership interests in companies, patents, and the relationships of senior officials (for example, service on a company's board of directors). Most reports focus on prominent and usually egregious cases of misconduct, as illustrated in Box 8-1.

Chapter 4 reviewed the results of a survey of department chairs in medical schools and large independent teaching hospitals that found that 27 percent of preclinical departments and 16 percent of clinical departments received income from intellectual property licensing (Campbell et al., 2007b). (This income may be seen as a benefit of the provisions of the Bayh-Dole Act, which allow institutions to patent discoveries resulting from federally funded research and to grant exclusive licenses for others to develop those discoveries.) The survey also found that ties to industry were common among department chairs, who served as consultants (27 percent), members of a scientific advisory board (27 percent), paid speakers (14 percent), company officers (7 percent), and company board members (11 percent). The committee did not locate institution-level data on company funding of biomedical research, but Chapter 4 reported that the majority of such research in the United States is commercially funded.

For institutions as well as individuals who provide health care, conflicts of interest also arise from provider reimbursement methods, whether these involve fee for service, prospective payment per case, pay for performance, or other arrangements. In addition, conflicts may arise from provider ownership interests, for example, hospital ownership of subsidiary specialty centers to which the hospital's physicians refer patients. As noted in Chapter 6, however, consideration of payment methods and ownership interests in medical facilities are beyond the scope of this report.

Among universities, a Congressional Research Service report concluded that patents typically account for a small percentage of university research and development funding and that most significant income from patents has tended to come from single "blockbuster" patents (Schacht, 2008). The report did not look specifically at biomedical research institutions. The Association of University Technology Managers, which conducts an annual survey of technology transfer activities (including the licensing of patents

and the launching of start-up companies), does not report information by scientific field.[1]

Most professional societies and disease-focused or patient advocacy groups do not make public the details of funding received from industry, but it appears that many groups depend on medical product companies for a significant share of their overall revenues and for specific activities (e.g., continuing medical education and the development of clinical practice guidelines). In connection with congressional inquiries about its relationships with pharmaceutical companies, the American Psychiatric Association (APA) reported that medical companies supplied about 28 percent of its annual income. An informal APA survey of other medical specialty societies indicated that this figure was about in the middle of the range of the income that companies provide these groups (from 2 to nearly 50 percent) (Stotland, 2008). An Associated Press story on pharmaceutical company spending to promote the awareness of fibromyalgia reported that companies contributed funds that amounted to 40 percent of the annual budget of the National Fibromyalgia Association (Perrone, 2009). Many groups list corporate donors but do not report how much of their income is derived from these donors. Groups that report sources of funding for activities such as clinical practice guideline development usually do not report the amount of company funding for an activity or what percentage of an activity's cost was accounted for by company funds. These data would assist with assessments of the risk of undue influence.

In a 2006 report for its board of directors, the American Academy of Family Physicians (AAFP) analyzed its resources and activities and concluded that it was not financially possible to forgo industry funding for any of its activities without imposing unacceptable cuts in services to members or increases in member costs. For its fiscal year 2006–2007 budget, AAFP projected that less than 38 percent of its income ($31 million of a total budget of $80 million) would come from dues and sales of products and services to members. Approximately 42 percent ($34 million) would come from the pharmaceutical industry, of which about 60 percent would come from advertising in the academy's journal and 13 percent would come from payments for exhibits at meetings (AAFP, 2006a). The report noted that the organization had sought to broaden its base of nondues funding beyond pharmaceutical companies by seeking grants from government and foundations for various activities and

[1] On the basis of its 2006 survey, the Association of University Technology Managers reported 12,672 actively managed licenses from patents as well as the introduction of 697 new products and 553 start-up companies (AUTM, 2007). It did not report the extent to which the institutions had financial stakes in the new products and companies. The survey covered 190 institutions, including 161 universities and 28 teaching hospitals and research institutions.

had also taken other steps to limit the influence of industry. If it stopped accepting all funding from industry, however, including journal advertising, the organization would have had to increase member dues by about $600 (to about $1,000 per year) to maintain the levels of service and the programs (e.g., existing educational activities at the same per program cost to members) that existed at that time (AAFP, 2006a).

The data presented in Chapter 6 showed that physician membership organizations obtained 49 percent of their income for accredited continuing medical education from a combination of commercial funding for activities, advertising, and exhibits at meetings. Medical school continuing medical education programs received about 62 percent of their income from these sources; for publishing and education companies, the figure was 73 percent.

RESPONSES TO INSTITUTIONAL CONFLICTS OF INTEREST

Federal regulations and laws have not consistently targeted institutional conflicts of interest. The U.S. Public Health Service (PHS) regulations on conflict of interest, which were issued in 1995 and which are included in Appendix B, cover only individual conflicts of interest and relationships with industry. Institutional conflicts of interest were deliberately not addressed (NIH, 1995). The guidance on financial relationships in research with human participants published by the U.S. Department of Health and Human Services discusses the identification and management of institutional as well as individual financial interests (HHS, 2004). The document suggests questions and procedures for institutional review boards (IRBs), investigators, and institutions to consider in evaluating institutional relationships. Federal antikickback rules apply to illegal payments to institutions as well as individuals. The recommendation by the Medicare Policy Advisory Commission (see Chapter 3) for industry reporting of consulting and other payments covers not only payments to physicians but also payments to medical schools, professional societies, and providers of continuing medical education (MedPAC, 2009). A bill introduced in the U.S. Congress in 2007 (S. 2029) and reintroduced in 2009 (Grassley, 2009) covers payments to individual physicians.

Several academic organizations have issued reports on institutional conflicts of interest, including the Association of American Medical Colleges (AAMC, 2002; AAMC-AAU, 2008), the Association of American Universities (AAMC-AAU, 2008), and the Council on Government Relations (COGR, 2003). The 2002 AAMC and 2008 AAMC-AAU reports dealt with institutional conflicts of interest in research with human participants.

The 2008 AAMC-AAU report was in part a response to evidence that academic medical centers had not implemented the recommendations set

forth in the 2002 AAMC report. In an AAMC survey of its members, only 38 percent of the institutions that responded reported that they had a conflict of interest policy that applied to the institution's financial interest, although another 37 percent reported that they were developing such a policy (Ehringhaus et al., 2008). For institutions that had policies, the documents typically covered equity in nonpublicly held companies (90 percent) or publicly held companies (77 percent), royalties (80 percent), payments for reaching designated milestones in the course of a study (73 percent), and substantial gifts from a research sponsor (73 percent). The majority of institutions that had policies applied them to senior officials (71 percent), governing board members (66 percent), and members of the IRB (81 percent). In addition, the majority of respondents reported creating organizational arrangements to separate institutional responsibility for research from responsibility for investment management (94 percent) or technology transfer (61 percent). Although the most serious problem identified in the survey was the lack of policies at a majority of institutions, another concern was the incomplete coverage by policies of significant institutional interests.

In addition to reiterating the importance of such policies, the 2008 AAMC-AAU report set forth several guiding principles for institutional conflict of interest policies. They were

- "research and financial decision-making processes and agents must be separated";
- "decisions about whether or not to pursue a particular human subjects research project in the presence of an institutional conflict of interest should be governed by a 'rebuttable presumption' against doing the research at or under the auspices of the conflicted institution" unless a compelling case can be made to justify an exception; and
- institutional conflict of interests "will be addressed consistently throughout the institution, such that those subject to institutional financial conflict of interest policies, specifically officials of the institution and the institutions themselves, are subject to substantive reporting, disclosure, and management of their financial interests." (pp. 14–16)

The report also recommended the creation of a standing institutional conflict of interest committee and discussed procedures for the reporting of institutional financial interests and the managing of relationships that were determined to be conflicts of interest. Strategies could involve divesting the institution of an equity interest in a company, requiring senior officials to remove themselves from involvement with making decisions that might affect their conflicting interest, declining to perform research in which the

institution has a financial stake (beyond the funding of the research itself), asking the IRB at another institution to review such research, or disclosing the institutional conflict of interest to research participants.

One university's policy lists several issues to be considered in evaluations of the circumstances that might justify institutional involvement in a human subjects research project despite a conflict of interest (University of Rochester, 2006). The case for the institution's participation in the project is stronger to the extent that

- the work is carried out at multiple sites (e.g., under the auspices of several institutions);
- the institution takes a relatively passive role in the conduct of the project (e.g., the gathering of data);
- the number of research subjects under the institution's supervision is small;
- an adverse effect on research subjects appears more likely if the institution is not used as a research site; and
- the investigators conducting the research or the university resources supporting the project are essential and are not readily available elsewhere.

In a position statement on organizational aspects of physician relationships with industry, the American College of Physicians (ACP) advised that "[m]edical professional societies that accept industry support or other external funding should be aware of potential bias and conflicts of interest" (Coyle et al., 2002b, p. 405). It recommended the adoption of explicit institutional policies on industry relationships, including policies that "avoid reliance on outside sources of support" and that guide the acceptance and disclosure of funding from industry and other outside sources. The ACP position on educational programs is that "it is unethical for academic institutions and educational organizations to accept any support that is explicitly or implicitly conditioned on industry's opportunity to influence the selection of instructors, speakers, invitees, topics, or content and materials of educational sessions" (Coyle et al., 2002b, p. 405).

In a 2006 statement, the Society for General Internal Medicine (SGIM) reported limits on the share of its annual operating budget that could come from external sources (SGIM, 2006). The limit on external sources of funding was 33 percent overall, with limits of 10 percent from health care-related for-profit entities in combination and 5 percent for any single such entity. (Thus, 67 percent of the operating budget must come from internal sources, such as member dues and fees.) Furthermore, the statement declared that the organization should not accept funds from

> for-profit companies (or not-for-profit entities funded largely by for-profit companies) for research or educational projects (including *individual* precourses, workshops or other presentations at the SGIM national or regional meetings) related to specific diseases, or to pharmaceuticals, medical devices, diagnostics, or other products or services purported to have direct health benefits to patients (regardless of whether the products are sold by that particular external funder). (p. 2)

The statement described such funds as "problematic" because their intent would seem to be "primarily promotional; that is, to directly or indirectly (through greater recognition of the disease in the population) encourage wider use of medical products, to the benefit of the sponsor" (p. 2). The statement stated that general meeting support may be solicited after program planners have determined the content of the meeting.

Chapter 6 discussed the actions that the Accreditation Council for Continuing Medical Education initiated to limit industry influence associated with providers' solicitation and acceptance of industry funding. Chapter 7 described the steps taken by some professional societies to insulate activities such as clinical practice guideline development from influence associated with industry funding. It also noted that some societies do not accept industry funding for guideline development.

SPECIAL CHALLENGES IN MANAGING INSTITUTIONAL CONFLICTS OF INTEREST

Although the committee found no systematic research on institutional conflicts of interest or the effects of institutional policies, it identified several challenges in managing such conflicts. One challenge is that identifying relevant institutional financial interests and conflicts may be difficult. Particularly in universities or other large institutions, no single individual or office may have knowledge of all such interests. Those responsible for identifying relationships may have to survey various parts of the institution to develop an inventory of relevant interests and relationship. In an academic medical center, for example, this inventory could cover the office responsible for technology transfer and intellectual property, the office or body that manages investments, the offices responsible for purchasing medical equipment, academic departments and other units that may receive gifts, and perhaps other offices or units as well. For senior officials, the usual process for disclosing individual financial interests will apply, although the review of disclosures will be at a higher level, for example, through a committee of the governing board, as recommended below.

Dealing with institutional conflicts of interest may be more difficult in some respects than dealing with individual conflicts of interest. In the case of individual conflicts in large institutions such as universities, medical

schools, and major teaching hospitals, opportunities for review usually exist at multiple levels of the institution and involve authorities who are relatively independent and do not stand to gain personally from the secondary interests in question. In contrast, an independent review for institutional conflicts of interest may be difficult because the institutional officers themselves may stand to benefit indirectly from the conflict of interest and may be reluctant to question current or proposed relationships with companies that seem likely to improve the institution's financial welfare. For example, the reputation and tenure of chief executives and other high-level officials may depend on their success in strengthening the financial health of their institution. If senior officials who oversee technology transfer, intellectual property, and research grants are also charged with managing institutional conflicts of interest, they may find it difficult to resist pursuing a grant or may be reluctant to divest the institution of a property interest even if such actions are necessary to manage the conflict. The leaders of professional societies and patient advocacy groups that depend significantly on member dues or individual contributions may be reluctant to reject grants from industry, even though they create a risk of undue influence over activities such as the development of clinical practice guidelines or educational programs.

The potential for conflicts of interest among senior institutional officials is one reason for the committee's recommendation below that the key responsibility for oversight of institutional conflicts of interest be lodged with an institution's governing body. It is also a reason for the recommendation that independent members—individuals not affiliated with the institution—be included on board committees that review and manage institutional conflicts of interest.

Because the potential financial gain from a secondary institution-level interest may not be personal for institutional officials, their decisions may be more easily rationalized as serving the institution rather than themselves—even when officials also stand to gain in personal reputation. In fact, the gains often do serve the institution's primary mission, for example, when returns on investments or licenses are distributed to worthy research, educational, or patient care activities. Nonetheless, it is precisely because this argument for benefit is so plausible (and often valid) that serious institution-level conflicts of interest may be ignored or may not be reviewed carefully to assess whether they might, on balance, undermine rather than promote the primary missions of the institution.

For similar reasons, the public may—at least initially—be more tolerant of institutional conflicts of interest than individual conflicts of interest and may expect that institutions will pursue relationships to advance research, expand educational activities, or increase clinical resources. This tolerance may, in turn, reinforce the inclination of institutional leaders to downplay

or ignore the resulting conflicts of interest. Because it is clear that universities and other health care institutions require resources to fulfill their missions and because society has encouraged institutions to pursue such resources, "[s]ociety may not view this as self-interested behavior and consequently may erroneously be more tolerant of circumstances in which an institution's financial interests may compromise the integrity of its missions than of similar situations involving individual conflict of interest" (Emanuel and Steiner, 1995, p. 263).

RECOMMENDATIONS

Because no decision maker in an institution is fully free of conflict in the case of institutional conflicts of interest, it is not possible to establish a fully independent process for assessing such conflicts. Although no perfect solution exists, the committee concluded that, on balance, the most suitable authority for making judgments about institutional conflicts is the board of trustees or an equivalent governing body.

In their fiduciary role, members of the board are responsible for giving priority to the longer-term interests of the institution. Because they stand at a greater distance from the daily pressures of decision making than an institution's senior officials, they should be able to assess more judiciously the positive or negative effects of financial interests on the institution's core mission. Board members also have access to comprehensive information about the finances of the institution, some of which may be confidential and not revealed to senior institutional officials. They may also be better positioned to help an institution's chief executive resolve disputes about conflicts of interest that involve different units within the institution. For example, in a university, faculty in the school of public health may be more concerned than faculty in the school of business about the potential for investments in certain products to create a risk to the missions of the whole institution.

In addition, the decisions made by a governing board are more salient within and beyond the institution than decisions made by staff. When the board takes up an issue, the concerned public is more likely to take notice.

RECOMMENDATION 8.1 The boards of trustees or the equivalent governing bodies of institutions engaged in medical research, medical education, patient care, or practice guideline development should establish their own standing committees on institutional conflicts of interest. These standing committees should

- **have no members who themselves have conflicts of interest relevant to the activities of the institution;**
- **include at least one member who is not a member of the board or an employee or officer of the institution and who has some relevant expertise;**
- **create, as needed, administrative arrangements for the day-to-day oversight and management of institutional conflicts of interest, including those involving senior officials; and**
- **submit an annual report to the full board, which should be made public but in which the necessary modifications have been made to protect confidential information.**

The standing board committee (or subcommittee) would regularly review the financial relationships of the institution itself to identify conflicts of interest with its primary mission or missions and would likewise review the financial relationships of senior officials. The board committee would also evaluate the adequacy of the policies and procedures established to deal with these relationships. This board committee would be different from the committee established to address individual conflicts of interests, as suggested in Recommendation 3.1.

Although the board should be accountable for institutional conflicts of interest, the committee recognizes that board members may not be well suited to carry out day-to-day oversight or conduct special investigations, especially in academic medical centers and other large institutions. The board may therefore decide to establish a mechanism for the day-to-day oversight of institutional conflicts of interest. This mechanism could take different forms at different institutions. For example, as AAMC and AAU have recommended, an academic institution might establish a faculty-staff committee that would oversee institutional conflicts of interest and that would be separate from any committee responsible for individual conflicts of interest. Such a committee (and any other support staff) could report to the board committee or to an officer of the institution who is not directly responsible for institutional investments, technology transfer, or research. Various options are reasonable; and the choices made may depend in part on the size, organization, and scope of an institution. In any case, the option selected should be consistent with the objectives of establishing and supporting governing board oversight of institutional conflicts of interest.

The recommended annual report from the board committee will provide an incentive for that committee to report on both what it has decided with respect to newly identified conflicts of interest and how its previous decisions (e.g., plans for eliminating or managing an institutional conflict of interest) have been implemented. Such reporting will also provide an incentive for rigorous review and accountability. The board committee is

more likely to be diligent in its reviews if its members know that if they miss potential problems, their failure may be publicized for all to see, should these problems become the subject of official investigations or media reports. In certain cases, a tension may exist between the countervailing goals of public disclosure and keeping confidential certain personnel information and certain facts about current or pending intellectual property. Thus, the board's public reports may exclude some details because the information is confidential, but such exclusions should be rare.

To speed the adoption of institutional conflict of interest policies, NIH should extend the 1995 PHS regulations on conflict of interest to cover institutional as well as individual financial interests for institutions that receive PHS research grants. Such rules would also call attention to the issue and encourage institutions that do not receive research funds but that are engaged in medical education, clinical care, or the development of practice guidelines to voluntarily take action to avoid and oversee potential conflicts of interest. Ideally, the development of new PHS rules would be harmonized with corresponding revisions in the regulations of the National Science Foundation.

RECOMMENDATION 8.2 The National Institutes of Health should develop rules governing institutional conflicts of interest for research institutions covered by current U.S. Public Health Service regulations. The rules should require the reporting of identified institutional conflicts of interest and the steps that have been taken to eliminate or manage such conflicts.

Although the new PHS rules should be consistent with the recommendation in Recommendation 8.1 and other recommendations in this report, they need not be highly prescriptive or rigid, particularly given that experience with institutional conflict of interest policies appears to be more limited and is less well documented than policies governing individual conflicts. Provisions for monitoring and enforcement are, however, important both at the level of the NIH extramural program and within research institutions. Consistent with current PHS rules on individual conflicts of interest, Recommendation 8.2 calls for grantee reporting to NIH of identified institutional conflicts of interest.

NIH can encourage the appropriate and reasonably consistent implementation of the regulations by providing supplementary explanations and guidance, as it has recently done for its policies and regulations on individual conflicts of interest (see Chapter 3). It can also bring grantee representatives together to discuss their experiences and identify good practices in policy development and implementation. In addition, NIH can develop or commission case studies on common situations that raise concerns over

conflicts of interest, such as institutional stakes in start-up companies that seek to sponsor research at the institution.

Although the 2008 AAMC-AAU report did not explicitly recommend governing board responsibility for policies on institutional conflicts of interest, their report can still provide useful guidance to NIH and to grantee institutions and a model for developing case studies to provide education on the evaluation of conflicts of interest. Because experience with and evaluations of institutional conflict of interest policies are limited, the investigation of such policies should be one focus of the research agenda recommended in Chapter 9. In addition, continued attention to this area—for example, further surveys of policy adoption—by AAMC would also be constructive.

The intent of the recommendations in this report is to promote a culture in which conflicts of interest are taken seriously by institutions and individuals engaged in medical research, education, and practice and practice guideline development. For this to happen, institutions must effectively manage their own conflicts and be seen to be doing so. The board and the senior officials set the tone for the institution. They should be accountable for making sure that their own institutional interests are in order.

9

Role of Supporting Organizations

Physicians, researchers, and the institutions that carry out medical research and education, provide patient care, and develop practice guidelines do not act in isolation but, rather, as part of complex intersecting systems. These systems can support or interfere with the adoption, implementation, and improvement of sound conflict of interest policies and can amplify or reduce the probability that financial relationships with industry may undermine primary professional or institutional obligations. Within these systems, a variety of organizations—public and private—can influence the policies and practices of institutions and uphold norms of professional integrity.

Chapter 1 distinguished between institutions that carry out medical research, education, clinical care, and practice guideline development and supporting organizations. Supporting organizations include accreditation and certification bodies, health insurance plans, membership groups such as the Association of American Medical Colleges (AAMC) and the World Association of Medical Journal Editors (WAME), and government agencies such as the National Institutes of Health (NIH). These entities may be seen as supporting organizations because they are in a position to influence the conflict of interest policies of the institutions that are the primary subject of this report. They can establish incentives for academic and other institutions to create more effective responses to conflicts of interest, including adopting and implementing the recommendations presented in this report. Some supporting organizations can also create incentives for individual physicians and researchers to follow conflict of interest policies and related codes of conduct. They can, more broadly, help create a culture of accountability that supports the integrity of professional judgment and sustains public confidence in that judgment.

The opportunities for supporting organizations to exert influence arise in different ways, depending on the roles and authority of the organization. Accrediting organizations set standards for medical schools, residency and fellowship programs, and institutions that provide health care. State agencies establish rules for the licensing and relicensing of individual physicians, and specialty boards design rules to certify and recertify physician specialists. The National Guidelines Clearinghouse sets conditions for the posting of clinical practice guidelines developed by professional societies and other groups. Public and private health insurers use a variety of financial and other incentives to influence the practices of institutions and individual physicians. The U.S. Department of Justice and the Office of Inspector General of the U.S. Department of Health and Human Services enforce antikickback and self-referral laws that prohibit or limit certain conflicts of interest. NIH promotes and oversees adherence to U.S. Public Health Service (PHS) regulations on conflict of interest for grantees. Professional societies and associations of health care and educational institutions articulate norms and ethical standards for their members. (Some professional societies are both organizations in this sense and also institutions that carry out research, education, and practice guideline development.) Although the Pharmaceutical Research and Manufacturers of America (PhRMA) and the Advanced Medical Technology Association (AdvaMed) represent companies, they establish codes of conduct for their members that may indirectly support medical professionals and institutions by discouraging member companies from interactions that create a risk of undue influence. (As described in Chapter 6, PhRMA and AdvaMed have indicated that they will publicly report on the companies that adopt their recently revised codes.)

Previous chapters have identified various shortcomings in the policies and practices of academic and other institutions. For example, as discussed in Chapter 3, some research institutions have been slow to adopt or adequately implement PHS requirements for conflict of interest policies, some academic medical centers have not adopted key AAMC policy recommendations, and some medical journals have not followed recommendations on conflict of interest from WAME and the International Committee of Medical Journal Editors (ICMJE). Furthermore, it may be difficult to determine a particular institution's policies. Postings on institutional websites may be incomplete or not up to date, and some institutions choose not to reveal their policies. Such a lack of transparency makes it difficult to assess whether an institution's policies are consistent with regulations or with recommendations of groups such as AAMC and WAME. As a result, opportunities to strengthen the institution's accountability for conflict of interest policies may be lost. Supporting organizations may promote consensus on the content of policies and also, in some situations, draw attention to the

failure of institutions to adopt and implement the policies, which may then stimulate corrective action.

This chapter discusses ways in which these diverse supporting organizations can cooperate with and influence the academic and other institutions that have the primary responsibility for dealing with conflicts of interest in medical research, education, and practice. The chapter begins by considering some of the productive forms that support and cooperation can take. The discussion emphasizes the roles of collaboration, consensus building, and incentives in making conflict of interest policies more effective and compliance with them less burdensome. It also recognizes that policies need to be backed by enforcement and sanctions. The chapter concludes with two recommendations that supplement the mostly mission-specific recommendations of earlier chapters. The first calls on supporting organizations to develop incentives for medical institutions to become more accountable for preventing, identifying, and managing conflicts of interest. The second calls for more research to provide a stronger evidence base for evaluating and improving conflict of interest policies.

HOW SUPPORTING ORGANIZATIONS CAN INFLUENCE MEDICAL INSTITUTIONS

Consensus Building and Collaboration

Consensus building and collaboration can operate within the institutions that are the focus of this report. Such efforts seek to engage those affected by policies in the process of developing them to improve the policies (e.g., by identifying and understanding obstacles to the success of the policies) and to win acceptance or buy in by those affected. Supporting organizations may likewise be more successful if they engage research, educational, and other institutions in the process of designing incentives and setting standards and if they give those institutions some discretion on how to reach specific performance goals. The leaders of those institutions are often in the best position to identify barriers to accountability (including burdensome or confusing administrative procedures) and to suggest ways to overcome those barriers. They are also well situated to identify and reduce the unintended negative consequences of proposed policies or procedures.

Some lessons for collaborative efforts that can be made to improve conflict of interest policies and practices are suggested by quality improvement initiatives within health care organizations. The typical quality improvement program in health care actively engages frontline caregivers and managers in an interdisciplinary process of identifying and analyzing problems in the quality of care, devising preventive or corrective interventions, monitoring outcomes, and modifying interventions on the basis of

the observed outcomes (Berwick, 1998). In this approach, the gathering and monitoring of outcomes data are crucial to identifying and reducing inappropriate variations in outcomes. In some cases, cross-institutional collaborations have helped institutions develop effective quality improvement programs. Some programs use transparency—the public reporting of organizational performance in relation to benchmarks—as a means of enhancing accountability and promoting competition to improve the quality of care. Accreditation agencies and voluntary groups have also encouraged this quality improvement process, and some universities have applied quality improvement models to university administration. The University of Wisconsin, for example, has an office of quality improvement that supports process improvement activities in administrative as well as academic areas, and its website showcases examples of activities that are potentially relevant for conflict of interest programs (University of Wisconsin, 2008).

There are, of course, significant differences between quality improvement procedures and conflict of interest policies. Nonetheless, the mechanisms of collaboration, consensus building, and outcome measurement can usefully guide the relationships between outside supporting organizations and institutions directly involved in medical research, education, and practice.

Some supporting organizations have been able to promote a consensus on important and often contentious aspects of conflict of interest policies. As described in earlier chapters, AAMC convened a broad group of affected parties that made recommendations about financial ties with industry in medical education (AAMC, 2008c). The parties included academic medical centers, teaching hospitals, industry, professional organizations, government agencies, and consumer groups. AAMC and the Association of American Universities convened another consensus development process to develop recommendations for improving the adoption and implementation of conflict of interest policies in human subjects research (AAMC-AAU, 2008). Over time, these and other initiatives have forged agreement on goals and recommendations regarding a number of controversial issues. Such collaborative consensus-building activities can address the practical concerns of individuals and institutions affected and make recommendations more credible and acceptable.

Incentives

Supporting organizations can devise incentives for institutions to adopt and implement conflict of interest policies. An example of an incentive for change in institutional policies and practices is the policy of the National Library of Medicine mentioned in Chapter 3. It will not cite or index articles from certain types of company-sponsored journal supplements unless they

include specific disclosures about any financial relationships that guest editors and authors have with the company or with the commercial products discussed in the supplement.

Just as the Medicare program and private health insurers have turned to pay-for-performance programs to provide incentives for quality improvement, so could insurance organizations offer incentives to institutions to adopt and maintain effective conflict of interest policies and to individuals to refrain from engaging in undesirable relationships with pharmaceutical, medical device, and biotechnology companies. For example, if preferred provider organizations publicly identified those participating physicians who agreed to decline gifts and marketing payments from industry, many physicians might decide that the benefits of being so identified outweigh the benefits of accepting such gifts and payments.

Particular incentives can have both positive and negative aspects. For example, when it rated medical schools on aspects of their conflict of interest policies, the American Medical Student Association used the "sunshine" of publicity in ways that were positive for the schools that it viewed as having good policies and possibly embarrassing for the schools that it viewed as having deficient policies (AMSA, 2008b). Although public reporting should enhance transparency and motivate policy change, it is also possible that it could merely promote the documentation of policies rather than meaningful oversight or change. Furthermore, public reporting could discourage relationships with industry that appropriately promote institutional missions and professional goals.

Enforcement and Sanctions

On the basis of the literature reviewed for Chapters 3 and 6, the actual imposition of penalties does not seem to figure prominently in the enforcement of conflict of interest policies, except for cases that involve offenses such as violations of anti-kickback and self-referral laws. NIH surveys and site visits have uncovered shortcomings in the content and application of PHS conflict of interest regulations for research grantees, and it appears that federal officials have penalized institutions or required quality improvement or remedial programs only rarely and only in cases in which problems have been identified in other ways (e.g., congressional or media investigations) (see Kaiser [2008]). As described in Chapter 3, NIH opposed a recommendation from the Office of the Inspector General that it require additional information from grantees about identified conflicts of interest and the means for their resolution.

Although they should be applied thoughtfully, sanctions have important roles in limiting and managing conflicts of interest. For example, at the most basic level, a process needs to be in place for institutions to determine

who has and who has not submitted the required financial disclosure forms. Usually, reminders should be sufficient for those who have not submitted forms, but penalties may also be needed, at least for blatant violations. Recent highly publicized incidents of significant underreporting of financial relationships to academic institutions call attention to the need for mechanisms to verify that the information disclosed is complete and accurate (e.g., through public reporting by industry of payments to physicians; see Recommendation 3.4). Again, sanctions may be appropriate for blatant cases of inaccurate disclosure. In addition, journal editors could take a stance more aggressive than they generally have thus far toward authors who violate their journals' disclosure and conflict of interest policies.

When noncompliance is egregious, penalties such as public censure or the suspension of individuals from certain positions (e.g., a principal investigator or department chair) may be necessary. Even accrediting agencies such as the Joint Commission (formerly the Joint Commission on the Accreditation of Healthcare Organizations) that have shifted from using more negative strategies to using more positive and cooperative strategies (e.g., acknowledging high performers and helping struggling performers improve) retain a range of sanctions for use against persistent or egregiously poor performers. Sanctions are, however, neither sufficient nor desirable as the sole instruments of accountability. They must be combined with a more ambitious and effective compliance strategy that employs collaboration, consensus building, and positive incentives.

RECOMMENDATIONS

Creating Incentives for Institutional Action

As this report has described, some institutions that carry out medical research, education, clinical care, and practice guideline development have no or inadequate conflict of interest policies. Some institutions may not even fully meet the requirements of current federal regulations, and others fail to undertake monitoring and enforcement activities. This report has also described shortcomings in adherence by individual physicians and researchers to academic medical center, journal, and other conflict of interest policies.

Ideally, physicians, scientists, and medical institutions should voluntarily adopt conflict of interest policies as a matter of professional responsibility and professional ethics. A commitment to patient well-being, valid scientific research, and evidence-based education would naturally lead professionals to voluntarily adopt strong measures to minimize the negative impact of conflicts of interest on objectivity and trust. No doubt many professionals have such an attitude and act on it. Realistically, however, the committee

is aware that behaviors are shaped not only by personal commitments but also by cultural and social forces. The environment in which health care professionals carry out research, teach, provide clinical care, and develop practice guidelines should promote and reinforce a professional's internal tendency to avoid relationships that pose an unacceptable risk of improperly influencing his or her judgment. The same is true for institutions. Their commitment to improve the content and application of conflict of interest policies is more likely to be effective if strong and consistent support from multiple independent organizations exists alongside government regulations. Thus, Recommendation 9.1 calls for an array of public and private groups (that is, supporting organizations) to create incentives to promote the widespread acceptance of policies to limit and manage conflicts of interest.

RECOMMENDATION 9.1 Accreditation and certification bodies, private health insurers, government agencies, and similar organizations should develop incentives to promote the adoption and effective implementation of conflict of interest policies by institutions engaged in medical research, medical education, clinical care, or practice guideline development. In developing the incentives, these organizations should involve the individuals and the institutions that would be affected.

A number of specific suggestions about incentives were discussed above and in the earlier chapters on medical research, education, and practice and practice guideline development. Box 9-1 summarizes these and other

BOX 9-1
Examples of Methods That Supporting Organizations Can Use to Strengthen Conflict of Interest Policies

Oversight bodies that oversee or regulate medical education and practice

- Accreditation and specialty certification bodies could set standards for the adoption of conflict of interest policies by organizations that offer undergraduate, graduate, and continuing medical education. These bodies could also collect and make public information on the educational institutions that follow those standards.
- State licensing boards could require that the continuing medical education courses required for relicensure be provided only by institutions that have adopted conflict of interest policies and other relevant recommendations presented in this report.

BOX 9-1 Continued

Membership organizations

- AAMC, PhRMA, and AdvaMed could collect and make public information on which of their member organizations have adopted their recommended conflict of interest policies or codes of conduct. (Note that the last two organizations have announced that they will post the names of companies that have pledged to follow their recently revised codes.)
- WAME could collect and make public information on which medical journals have adopted the authorship, ghostwriting, and conflict of interest policies consistent with its policy statements and those of ICMJE.
- Professional societies and associations of professional organizations could set standards for conflict of interest provisions in professional codes and membership criteria, make their policies public, and establish awards for groups that have exemplary conflict of interest policies and procedures.

Private health insurance plans

- Private health insurance plans could establish incentives for hospitals and individual physicians to adopt conflict of interest policies, as recommended in this report. For example, the adoption of such policies could be a criterion for an institution to be a center of excellence or for a physician to be a member of a preferred provider program. Alternatively, the lists of physicians in a plan could include information on whether a physician has agreed to certain conflict of interest provisions. Health insurers could also establish similar incentives for other institutions that provide health care, such as skilled nursing facilities or dialysis units.
- Business coalitions, such as the Leapfrog Group, the National Business Group on Health, and the Pacific Business Group on Health, could encourage employers who purchase health insurance to provide financial incentives for health care plans and health care providers to adopt the relevant recommendations presented in this report.

Government agencies

- NIH could collect and make public information on research institutions that have policies that are not in full compliance with 1995 PHS regulations. It could expand its recent efforts to provide more guidance to grantee institutions covered by the PHS regulations, and it could also analyze a sample of grantee conflict of interest reports to understand and evaluate how grantees eliminate or manage those conflicts of interest that are identified.
- The National Library of Medicine could identify in its online databases those journals that have adopted the authorship guidelines of ICMJE or WAME. For example, a symbol could be placed near the name of the journal when it appears in the listing of an article.
- The National Guidelines Clearinghouse could include only clinical practice guidelines that follow the recommendations presented in this report, including the provision of information about the sponsoring group's conflict of interest policies, the sources and amounts of industry funding for the guideline, the steps taken to identify participants without conflicts of interest, and the limits placed on participation in decision making by members with conflicts of interest.

examples of what supporting organizations can do. Many involve collecting and making public information about which institutions have adopted and applied the recommended policies. The committee expects that the prospect of such reporting would motivate institutions to close the gaps and loopholes in their conflict of interest policies or to provide a vigorous justification of why their policies depart from the recommendations.

If voluntary measures to deal with conflicts of interest are perceived to be weak or ineffectual, then calls for additional legislation or regulation or the more intrusive or punitive enforcement of existing laws will likely grow. The opportunity to preempt sweeping and potentially burdensome legal requirements should give a sense of urgency to voluntary efforts to establish and implement conflict of interest policies that reassure the public and those who make public policy. Government directives and prohibitions can be blunt instruments for dealing with conflict of interest problems, which often call for subtle judgments of risks and benefits and which involve many uncertainties. They also may not be as sensitive as voluntarily adopted measures to the administrative burdens of compliance or the possibility of unintended adverse consequences. This caution should not be interpreted as an endorsement of lax agency oversight or the lax application of existing conflict of interest rules.

Building the Evidence Base for Policy Improvement

As has been observed throughout this report, little systematic information about conflict of interest policies is available. This lack of information extends from basic descriptive information about policies to evaluations of the effects of different kinds of policies and implementation strategies.

RECOMMENDATION 9.2 To strengthen the evidence base for the design and application of conflict of interest policies, the U.S. Department of Health and Human Services should coordinate the development and funding of a research agenda to study the impact of conflicts of interest on the quality of medical research, education, and practice and on practice guideline development and to examine the positive and negative effects of conflict of interest policies on these outcomes.

Within the U.S. Department of Health and Human Services, NIH, the Agency for Healthcare Quality and Research, and the Food and Drug Administration should be involved in defining a research agenda that addresses questions and concerns about implementing, enforcing, and possibly refining conflict of interest policies. The research agenda not only should investigate government policies, however, but also should investigate the

policies that academic medical centers, professional societies, and other private groups have adopted.

Research on the characteristics and outcomes of conflict of interest policies would be desirable for several reasons. First, research could clarify which relationships are associated with higher or lower risks of undue influence or loss of trust, as well as the magnitudes of such associations. Second, such research may identify which conflict of interest policies and procedures are effective in achieving the desired outcomes and under what circumstances various policies are likely to be more effective. These data could then guide modifications in policies and procedures. Third, research on conflict of interest policies may identify unintended adverse consequences of well-intentioned policies and, in turn, inform corrective policy changes. Unintended negative consequences might include disproportionate administrative burdens and the inhibition of constructive collaborations between academia and industry. Strengthening the evidence base should allow institutions to improve their conflict of interest policies to better protect the integrity of their missions and to maintain the trust of the public.

A

Study Activities

During 2006, the Institute of Medicine's (IOM's) Board on Health Sciences Policy began to discuss threats to public trust in biomedical research and medicine created by certain types of financial relationships between pharmaceutical, medical device, and biotechnology companies and researchers based in universities and federal agencies. As the discussion expanded, others expressed concerns about conflicts of interest in medical education, especially continuing medical education. The IOM was also approached about whether it would examine financial relationships and conflicts of interest as they affect the publication of research and the development of clinical practice guidelines.

In response, the IOM developed a proposal for a broad-ranging study that would examine conflicts of interest across medical research, medical education, clinical practice, and practice guideline development. It secured funding for the study from both public and private sources and appointed a 17-member committee to oversee the study. The charge to the committee was to develop a consensus report that would

- examine and describe conflicts of interest involving health care professionals and industry in different contexts, including, for example, the conduct of research, the education of health care professionals, the development of practice guidelines, the provision of patient care, and the management of academic and other institutions;
- propose principles to inform the design of policies, guidelines, and other tools to identify and manage conflicts of interest in these contexts without damaging constructive collaboration with industry; and
- consider methods to disseminate, promote, implement, and evaluate these principles and policies.

The committee met six times between November 2007 and October 2008. It held public sessions at its first four meetings to hear views from a wide range of experts and interested parties. The May 2008 meeting included a workshop on conflict of interest issues in basic research and another on conflict of interest issues in the development of clinical practice guidelines. The agendas for the public meetings are listed below. The committee also invited written statements of views from approximately 50 additional organizations; those that submitted statements are listed.

INSTITUTE OF MEDICINE
COMMITTEE ON CONFLICT OF INTEREST IN MEDICAL RESEARCH, EDUCATION, AND PRACTICE

Keck Center of the National Academies
November 5–6, 2007—Open Sessions

November 5

3:00 **Welcome and Introductions**
Bernard Lo, M.D., Committee Chair

3:10 **Overview of Conflicts of Interest in Medical Research, Education,** and Practice
Robert Steinbrook, M.D., National Correspondent, *New England Journal of Medicine*
Eric Campbell, Ph.D., Associate Professor, Institute for Health Policy, Massachusetts General Hospital, and Harvard University
Greg Koski, M.D., Ph.D., Senior Scientist, Institute for Health Policy, Massachusetts General Hospital, and Harvard University
Peter Lurie, M.D., M.P.H., Deputy Director, Public Citizen's Health Research Group

Discussion

5:00 **Adjourn**

November 6

8:30 **Welcome and Introductions**

8:35 **Perspectives from Industry**
Garry A. Neil, M.D., Group President, Johnson & Johnson

8:50 **Discussion with Study Sponsor**
Christine Cassel, M.D., President, American Board on Internal Medicine Foundation

9:05 **Conflict of Interest in Medical Research**
Cary P. Gross, M.D., Associate Professor of Medicine, Yale University
David Korn, M.D., Senior Vice President for Biomedical and Health Sciences Research, Association of American Medical Colleges

Discussion

10:10 **Break**

10:30 **Conceptual Issues in Conflict of Interest**
Ezekiel J. Emanuel, M.D., Ph.D., Chair, Department of Bioethics, Magnuson Clinical Center, National Institutes of Health

Discussion

11:10 **Discussion with Study Sponsor**
Elias A. Zerhouni, M.D., Director, National Institutes of Health

Noon **Adjourn**

INSTITUTE OF MEDICINE
COMMITTEE ON CONFLICT OF INTEREST IN MEDICAL RESEARCH, EDUCATION, AND PRACTICE

Keck Center of the National Academies
January 21, 2008—Open Session

1:00 **Welcome, Introductions, and Statement About the Meeting**
Bernard Lo, M.D., Committee Chair

1:10 **Conflict of Interest in Medical Education**
Suzanne Fletcher, M.D., M.Sc., Professor Emerita of Ambulatory Care and Prevention, Harvard Medical School
Michael Steinman, M.D. (*by conference call*), Assistant Professor of Medicine, San Francisco Veterans Affairs Medical Center and University of California, San Francisco

Discussion

2:10 **Conflict of Interest in Medical Education**
Murray Kopelow, M.D., Chief Executive, Accreditation Council for Continuing Medical Education
Ingrid Philibert, M.H.A., M.B.A., Senior Vice President, Department of Field Activities, Accreditation Council for Graduate Medical Education
F. Daniel Duffy, M.D., Senior Adviser to the President, American Board of Medical Specialties

Discussion

3:10 **Break**

3:30 **Perspectives from Industry**
Paul Citron, Ph.D., Retired, Vice President for Technology Policy and Academic Affairs, Medtronic
Cathryn Clary, M.D., Vice President, U.S. External Medical Affairs, Pfizer, Inc.

10:45 Lessons Learned I: Developing and Implementing Medical School Conflict-of-Interest Policies
Philip A. Pizzo, M.D., Carl and Elizabeth Naumann Dean and Professor of Pediatrics and of Microbiology and Immunology, Stanford University School of Medicine

Joseph B. Martin, M.D., Ph.D., Edward R. and Anne G. Lefler Professor of Neurobiology, and Dean, Harvard Medical School, 1997–2007

Questions and Discussion

Follow-up Questions and Discussion for Earlier Panels

12:00 Lunch break

1:00 Statements from Organizations
American Medical Association
Mark A. Levine, M.D., Chair, Council of Ethical and Judicial Affairs

American College of Physicians
Joel S. Levine, M.D., Chair, Board of Regents and Senior Associate Dean for Clinical Affairs, University of Colorado School of Medicine

American Psychiatric Association
Carolyn B. Robinowitz, M.D., President and Clinical Professor of Psychiatry at Georgetown and George Washington Universities

American College of Cardiology
John C. Lewin, M.D., C.E.O.
Sidney C. Smith Jr., M.D., Professor of Medicine and Director, Center for Cardiovascular Science and Medicine, University of North Carolina, Chapel Hill

American Medical Student Association
Brian Palmer, M.D., M.P.H., Past President and Psychiatry Resident, Massachusetts General Hospital/McLean Hospital

Questions and Discussion

2:30 Break

3:00 Lessons Learned II: Developing and Implementing Conflict-of-Interest Policies
David Korn, M.D., Senior Vice President for Biomedical and Health Sciences Research Association of American Medical Colleges
Leo Furcht, M.D., Past President, Federation of American Societies for Experimental Biology and Allen Pardee, Professor and Head of Laboratory Medicine and Pathology, University of Minnesota School of Medicine
Harold C. Sox, M.D., International Committee of Medical Journal Editors, and Editor, *Annals of Internal Medicine*

Questions and Discussion

4:15 Continued Questions and Discussion and Public Comment

5:00 Adjourn

Organizations Submitting Written Statements
In addition to the organizations presenting statements during the March meeting, the following organizations provided written statements to the committee:

Accreditation Council for Continuing Medical Education
Alliance for Continuing Medical Education
Alzheimer's Association
American Academy of Family Physicians
American Academy of Ophthalmology
American Academy of Orthopedic Surgeons
American Academy of Pediatrics
American Board of Medical Specialties
American Society of Hematology
American Thoracic Society
Coalition for Healthcare Communication
Infectious Diseases Society of America
National Kidney Foundation
North American Spine Society
Society for Academic Continuing Medical Education

May 22, 2008—Open Session

Conflict of Interest in Basic and Translational Research

8:15 Welcome, Introductions, and Chair's Statement
Bernard Lo, M.D., Committee Chair

8:35 Additional Perspectives on Professional Society Policies
Kenneth Kaushansky, M.D., President, American Society of Hematology and Chair and Helen M. Ranney Professor, Department of Medicine, University of California, San Diego

9:00 **Perspectives on Financial Relationships and Conflicts of Interest in Basic and Early-Stage Translational Research: Part 1**
Leslie Z. Benet, Ph.D., Professor, Department of Biopharmaceutical Sciences, University of California, San Francisco
Gail Cassell, Ph.D., Vice President, Scientific Affairs, and Distinguished Lilly Research Scholar for Infectious Diseases, Eli Lilly and Company
Edward Benz, M.D., (*by telephone*), President, Dana-Farber Cancer Institute

Discussion

10:10 **Break**

10:30 **Perspectives on Financial Relationships and Conflicts of Interest in Basic and Early-Stage Translational Research: Part 2**
Hamilton Moses III, M.D., Chair, The Alerion Institute
Leo Furcht, M.D., Past President, Federation of American Societies for Experimental Biology and Allen Pardee, Professor and Head of Lab Medicine and Pathology, University of Minnesota School of Medicine

Discussion

11:25 **Financial Disclosures and Trust in Health Care Professionals**
Mark Hall, J.D., Professor of Law and Public Health, Wake Forest University School of Law
Kevin Weinfurt, Ph.D., Associate Professor of Psychiatry and Behavioral Sciences, and of Psychology and Neuroscience, Duke Clinical Research Institute

Discussion

Noon **Lunch break**

Conflict of Interest in Clinical Practice Guidelines

1:00 **Welcome, Introductions, and Chair's Statement**
Bernard Lo, M.D., Committee Chair

1:15 Individual and Organizational Financial Relationships with Industry
Elizabeth Boyd, Ph.D., Assistant Vice President for Research, Compliance and Policy, University of Arizona

Discussant: Mary Nix, M.S., Health Scientist Administrator, National Guideline Clearinghouse, Agency for Healthcare Research and Quality

Discussion

2:00 Organizational Policies, Practices, and Challenges in Developing and Implementing Conflict-of-Interest and Related Policies
Dina Michels, Esq., Vice President and General Counsel, American Society of Clinical Oncology
Murray Sagsveen, J.D., General Counsel, American Academy of Neurology
Sidney C. Smith, Jr., M.D., American College of Cardiology, and Professor of Medicine and Director, Academic Center for Cardiovascular Disease
Mary Barton, M.D., M.P.P., Scientific Director, U.S. Preventive Services Task Force, and University of North Carolina

Discussants:
Fran Visco, President, National Breast Cancer Coalition
Alvin Lever, M.A., C.E.O., American College of Chest Physicians
Sandra Zelman Lewis, Ph.D., Assistant Vice President, American College of Chest Physicians
Henry Masur, M.D., Chief, Department of Critical Care Medicine, National Institutes of Health Clinical Center
John C. Ring, M.D., Director, Policy Research and Development, American Heart Association

3:00 Break

3:20 Continued Discussion of Organizational Policies and Practices

4:00 Systematic Reviews and Other Strategies to Protect Against Bias in Guidelines Development
Holger Schunemann, M.D., Ph.D., Associate Professor of Medicine, University of Buffalo, and Italian National Cancer Institute, Rome, Italy

Discussion (all participants)

5:00 Public Comments

5:30 Adjourn

B

U.S. Public Health Service Regulations: Objectivity in Research (42 CFR 50)

TITLE 42—PUBLIC HEALTH
CHAPTER I—PUBLIC HEALTH SERVICE,
DEPARTMENT OF HEALTH AND HUMAN SERVICES

SUBCHAPTER D—GRANTS
PART 50—POLICIES OF GENERAL APPLICABILITY

Subpart F–Responsibility of Applicants for Promoting Objectivity in Research for Which PHS Funding Is Sought

Sec. 50.601 — Purpose.

This subpart promotes objectivity in research by establishing standards to ensure there is no reasonable expectation that the design, conduct, or reporting of research funded under PHS [Public Health Service] grants or cooperative agreements will be biased by any conflicting financial interest of an Investigator.

Sec. 50.602 — Applicability.

This subpart is applicable to each Institution that applies for PHS grants or cooperative agreements for research and, through the implementation of this subpart by each Institution, to each Investigator participating in such research (see Sec. 50.604(a)); provided that this subpart does not apply to SBIR [Small Business Innovation Research] Program Phase I applications. In those few cases where an individual, rather than an institution, is an appli-

cant for PHS grants or cooperative agreements for research, PHS Awarding Components will make case-by-case determinations on the steps to be taken to ensure that the design, conduct, and reporting of the research will not be biased by any conflicting financial interest of the individual. [p35816]

Sec. 50.603 — Definitions.

As used in this subpart:

HHS means the United States Department of Health and Human Services, and any components of the Department to which the authority involved may be delegated.

Institution means any domestic or foreign, public or private, entity or organization (excluding a Federal agency).

Investigator means the principal investigator and any other person who is responsible for the design, conduct, or reporting of research funded by PHS, or proposed for such funding. For purposes of the requirements of this subpart relating to financial interests, "Investigator" includes the Investigator's spouse and dependent children.

PHS means the Public Health Service, an operating division of the U.S. Department of Health and Human Services, and any components of the PHS to which the authority involved may be delegated.

PHS Awarding Component means the organizational unit of the PHS that funds the research that is subject to this subpart.

Public Health Service Act or PHS Act means the statute codified at 42 U.S.C. 201 et seq.

Research means a systematic investigation designed to develop or contribute to generalizable knowledge relating broadly to public health, including behavioral and social-sciences research. The term encompasses basic and applied research and product development. As used in this subpart, the term includes any such activity for which research funding is available from a PHS Awarding Component through a grant or cooperative agreement, whether authorized under the PHS Act or other statutory authority.

Significant Financial Interest means anything of monetary value, including but not limited to, salary or other payments for services (e.g., consulting fees or honoraria); equity interests (e.g., stocks, stock options or other own-

ership interests); and intellectual property rights (e.g., patents, copyrights and royalties from such rights). The term does not include:

(1) Salary, royalties, or other remuneration from the applicant institution;

(2) Any ownership interests in the institution, if the institution is an applicant under the SBIR Program;

(3) Income from seminars, lectures, or teaching engagements sponsored by public or nonprofit entities;

(4) Income from service on advisory committees or review panels for public or nonprofit entities;

(5) An equity interest that when aggregated for the Investigator and the Investigator's spouse and dependent children, meets both of the following tests: Does not exceed $10,000 in value as determined through reference to public prices or other reasonable measures of fair market value, and does not represent more than a five percent ownership interest in any single entity; or

(6) Salary, royalties or other payments that when aggregated for the Investigator and the Investigator's spouse and dependent children over the next twelve months, are not expected to exceed $10,000.

Small Business Innovation Research (SBIR) Program means the extramural research program for small business that is established by the Awarding Components of the Public Health Service and certain other Federal agencies under Pub. L. 97-219, the Small Business Innovation Development Act, as amended. For purposes of this subpart, the term SBIR Program includes the Small Business Technology Transfer (STTR) Program, which was established by Pub. L. 102-564.

Sec. 50.604 — Institutional responsibility regarding conflicting interests of investigators.

Each Institution must:

(a) Maintain an appropriate written, enforced policy on conflict of interest that complies with this subpart and inform each Investigator of that policy, the Investigator's reporting responsibilities, and of these regulations. If the Institution carries out the PHS-funded research through subgrantees, contractors, or collaborators, the Institution must take reasonable steps to

ensure that Investigators working for such entities comply with this subpart, either by requiring those Investigators to comply with the Institution's policy or by requiring the entities to provide assurances to the Institution that will enable the Institution to comply with this subpart.

(b) Designate an institutional official(s) to solicit and review financial disclosure statements from each Investigator who is planning to participate in PHS-funded research.

(c)(1) Require that by the time an application is submitted to PHS each Investigator who is planning to participate in the PHS-funded research has submitted to the designated official(s) a listing of his/her known Significant Financial Interests (and those of his/her spouse and dependent children):

(i) That would reasonably appear to be affected by the research for which PHS funding is sought; and

(ii) In entities whose financial interests would reasonably appear to be affected by the research.

(2) All financial disclosures must be updated during the period of the award, either on an annual basis or as new reportable Significant Financial Interests are obtained.

(d) Provide guidelines consistent with this subpart for the designated official(s) to identify conflicting interests and take such actions as necessary to ensure that such conflicting interests will be managed, reduced, or eliminated.

(e) Maintain records of all financial disclosures and all actions taken by the Institution with respect to each conflicting interest for at least three years from the date of submission of the final expenditures report or, where applicable, from other dates specified in 45 CFR 74.53(b) for different situations.

(f) Establish adequate enforcement mechanisms and provide for sanctions where appropriate.

(g) Certify, in each application for the funding to which this subpart applies, that:

(1) There is an effect at that Institution a written and enforced administrative process to identify and manage, reduce or eliminate conflicting interests

with respect to all research projects for which funding is sought from the PHS,

(2) Prior to the Institution's expenditure of any funds under the award, the Institution will report to the PHS Awarding Component the existence of a conflicting interest (but not the nature of the interest or other details) found by the institution and assure that the interest has been managed, reduced or eliminated in accordance with this subpart; and, for any interest that the Institution identifies as conflicting subsequent to the Institution's initial report under the award, the report will be made and the conflicting interest managed, reduced, or eliminated, at least on an interim basis, within sixty days of that identification;

(3) The Institution agrees to make information available, upon request, to the HHS regarding all conflicting interests identified by the Institution and how those interests have been managed, reduced, or eliminated to protect the research from bias; and

(4) The Institution will otherwise comply with this subpart. [p35817]

Sec. 50.605 — Management of conflicting interests.

(a) The designated official(s) must: Review all financial disclosures; and determine whether a conflict of interest exists and, if so, determine what actions should be taken by the institution to manage, reduce or eliminate such conflict of interest. A conflict of interest exists when the designated official(s) reasonably determines that a Significant Financial Interest could directly and significantly affect the design, conduct, or reporting of the PHS-funded research. Examples of conditions or restrictions that might be imposed to manage conflicts of interest include, but are not limited to:

(1) Public disclosure of significant financial interests;

(2) Monitoring of research by independent reviewers;

(3) Modification of the research plan;

(4) Disqualification from participation in all or a portion of the research funded by the PHS;

(5) Divestiture of significant financial interests; or

(6) Severance of relationships that create actual or potential conflicts.

(b) In addition to the types of conflicting financial interests described in this paragraph that must be managed, reduced, or eliminated, an Institution may require the management of other conflicting financial interests, as the Institution deems appropriate.

Sec. 50.606 — Remedies.

(a) If the failure of an Investigator to comply with the conflict of interest policy of the Institution has biased the design, conduct, or reporting of the PHS-funded research, the Institution must promptly notify the PHS Awarding Component of the corrective action taken or to be taken. The PHS Awarding Component will consider the situation and, as necessary, take appropriate action, or refer the matter to the Institution for further action, which may include directions to the Institution on how to maintain appropriate objectivity in the funded project.

(b) The HHS may at any time inquire into the Institutional procedures and actions regarding conflicting financial interests in PHS-funded research, including a requirement for submission of, or review on site, all records pertinent to compliance with this subpart. To the extent permitted by law, HHS will maintain the confidentiality of all records of financial interests. On the basis of its review of records and/or other information that may be available, the PHS Awarding Component may decide that a particular conflict of interest will bias the objectivity of the PHS-funded research to such an extent that further corrective action is needed or that the Institution has not managed, reduced, or eliminated the conflict of interest in accordance with this subpart. The PHS Awarding Component may determine that suspension of funding under 45 CFR 74.62 is necessary until the matter is resolved.

(c) In any case in which the HHS determines that a PHS-funded project of clinical research whose purpose is to evaluate the safety or effectiveness of a drug, medical device, or treatment has been designed, conducted, or reported by an Investigator with a conflicting interest that was not disclosed or managed as required by this subpart, the Institution must require the Investigator(s) involved to disclose the conflicting interest in each public presentation of the results of the research.

Sec. 50.607 — Other HHS regulations that apply.

Several other regulations and policies apply to this subpart.

They include, but are not necessarily limited to:

42 CFR Part 50, Subpart D–Public Health Service grant appeals procedure

45 CFR Part 16–Procedures of the Departmental Grant Appeals Board

45 CFR Part 74–Uniform Administrative Requirements for Awards and Subawards to Institutions of Higher Education, Hospitals, Other Non-Profit Organizations, and Commercial Organizations; and Certain Grants and Agreements with States, Local Governments and Indian Tribal Governments

45 CFR Part 76–Government-wide debarment and suspension (non-procurement)

45 CFR Part 79–Program Fraud Civil Remedies

45 CFR Part 92–Uniform Administrative Requirements for Grants and Cooperative Agreements to State and Local Governments

C

Conflict of Interest in Four Professions: A Comparative Analysis

Michael Davis and Josephine Johnston***

This paper presents a selective survey of the ways in which important professions other than medicine understand and regulate conflicts of interest. The professions evaluated here—law (lawyers), accountancy (certified public accountants [CPAs]), architecture, and engineering—each differ from medicine in having clients or employers rather than patients as the focus of concern. The difference is not simply one of terminology. A client or an employer is not necessarily human. Many are corporations or governments. Even the human clients differ from patients. With some exceptions (e.g., clients accused of crimes), they are typically healthy, calm, and relatively well-informed about the service to be provided; they are seldom as vulnerable as a physician's patient typically is. A client or employer simply asks that something be done (a building put up, a machine designed, a contract drawn, or a company audited). Emergencies are much rarer in these professions than they are in medicine, and time to think through a problem is more plentiful. Because of their relative sophistication and bargaining strength (compared both with patients and with the professional in question), clients or employers need not readily consent to accept the conflicts disclosed to them; they are more likely to insist that a conflict be avoided or resolved or to use the conflict to better the bargain. In other words, law, ac-

* Michael Davis, Ph.D., is a senior fellow within the Center for Study of Ethics in the Professions and a professor of philosophy in the Humanities Department, Illinois Institute of Technology.

** Josephine Johnston, L.L.B., is a research scholar at the Hastings Center, Garrison, New York.

counting, architecture, and engineering are professions in which one might expect much less concern with conflicts of interest than in medicine.

Although these are the chief differences between medicine and the professions discussed here, they are not the only ones. These other professions differ substantially in size from medicine—and from each other. Physicians outnumber architects in the United States by about 10 to 1, engineers outnumber physicians by about 3 to 1, and the numbers of individuals in the other professions fall somewhere in between. Importantly, only one profession, engineering, does much that physicians would recognize as scientific research.

The professions evaluated here were chosen because none is a close analogue of medicine. Medicine tends to be the model for adjacent professions (osteopathy, dentistry, pharmacy, nursing, and so on). The comparison of medicine with an adjacent profession would provide less contrast and therefore less understanding of conflict of interest as a general problem for professions. All of the professions discussed here have substantial experience with employment in large organizations. Two of the professions—engineering and accounting—have a long history of employment in such organizations. Only a small minority of engineers has ever been self-employed in the way that most physicians, except those in research and teaching, were until recently. Even self-employed architects, lawyers, and accountants often work for and in large organizations in a way that physicians have only recently begun to do in large numbers. Looking at how these nonmedical professions respond to the conflicts of interest that are more likely to arise in large organizations should help physicians both look critically at present arrangements and anticipate the future. Finally, these professions all recognize conflicts of interest as posing a threat to the integrity of the profession and have developed ethics rules to address the threat.

TERMINOLOGY

"Conflict of interest" is not an old term. The first court case to use it in something like the sense that is now standard occurred in 1949.[1] Federal legislation first addressed conflict of interest in the late 1950s.[2] The *Index of Legal Periodicals* had no heading for "conflict of interest" until 1967; *Black's Law Dictionary* had none until 1979. No ordinary dictionary of English seems to have had an entry for "conflict of interest" before 1971. The term also began to appear in codes of ethics in the 1970s, although related terms, such as "adverse interest," "conflicting interest," "bias,"

[1] *In re Equitable Office Bldg. Corp.*, D.C.N.Y., 83 F. Supp. 531.

[2] Staff report of the Antitrust Subcommittee (Subcommittee No. 5) of House Judiciary Committee, 85th Cong., 2d sess., Federal Conflict of Interest Legislation (Comm. Print 1958).

"prejudice," and the like appeared in codes much earlier.[3] This short history may explain, at least in part, the variation in how the term is used among professions. We are all trying to keep pace with the usage.

The term "conflict of interest" is not self-explanatory but is an idiom or term of art (a term designed to pick out a phenomenon until then lacking a suitable name). For the professions discussed here, the term groups together a range of scenarios in which the professional judgment of the individual in question risks being compromised.[4] These professions do not use explicit definitions of "conflict of interest" but instead describe in their codes a variety of situations that fall under the heading "conflict of interest" and that must either be avoided or managed in specified ways. For example, the definitions section of the American Bar Association's (ABA's) *Model Rules of Professional Conduct* includes definitions of "informed consent" and "fraud" but not "conflict of interest."[5] Instead, situations labeled conflicts of interest are described in the *Model Rules*.[6] Similarly, the American Institute of Certified Public Accountants' (AICPA's) *Code of Professional Conduct* includes a definition of some of the terms used in its conflict of interest rules, such as "immediate family" but not "conflict of interest." In fact, AICPA's Code does not use the term "conflict of interest" at all, speaking instead of various threats to "independence" and "objectivity," including the threat posed by certain financial interests.[7]

The major concern uniting the professions' use of the term is to protect the judgment of individual professionals from undue influence, whether the risk arises from gifts or kickbacks; an individual's personal (generally financial) interests; or the interests of family members, colleagues, or current and former clients. In some of the professions, a situation—for example, the representation of both plaintiff and defendant in the same legal case—is labeled a conflict of interest when it would be described as a conflict of obligations or responsibilities in the report to which this paper is an appendix (see Chapter 2) because neither obligation would be considered secondary to the other.

For all of the professions discussed in this paper, a certain sort of expert

and trustworthy judgment in individual situations (the judgment characteristic of the profession) is what makes members of the profession useful. A conflict of interest makes that judgment unreliable just when reliability is needed. A conflict of interest is therefore always considered a threat to the good that the profession seeks to achieve and is often also a threat to the profession's reputation. That is what makes having a conflict of interest a serious concern in professional ethics.

The next four sections of this paper consider in detail how the four professions on our list understand conflict of interest, respond to it, and why. The final section summarizes and compares the professions and identifies approaches from which medical research, education, and practice might learn.

LAWYERS

The main legal professions—lawyers and judges—have traditionally taken conflict of interest very seriously. Because justice is to be fairly meted out, interests that might cause a judge to be or appear to be partial are also generally prohibited. Although lawyers owe obligations to the legal system and the public, their primary obligation is to their clients; interests that might interfere with this obligation are generally to be avoided. The legal professions have some of the strictest rules about conflict of interest and have a long history of examining and enforcing those rules. In the interests of space, the focus here is on lawyers because their work, in most respects, is more like that of physicians than is the work of judges. (Judges are more like physicians serving on drug and device approval panels or as authors of review articles, whose charge is to weigh all the evidence and reach a reasoned and impartial decision.[8])

In legal practice, conflicts of interest are conceptualized in the context of the attorney-client relationship, which is protected by very strong obligations of loyalty and confidentiality. Broadly speaking, two kinds of conflict are understood to arise in that relationship: first, conflicts between the interests of two or more clients (whether they be current clients or a current client and a former client) and, second, conflicts between the interests of one or more clients and the personal interests of the attorney.

The first kind of conflict is created by the act of entering into a certain attorney-client relationship. For that reason, lawyers routinely conduct "conflicts checks" before taking on a new client or a new file from an existing client. The second kind of conflict can be created by either enter-

[8] For an example of rules of professional conduct for judges, see New York State Commission on Judicial Conduct, Rules of Conduct, at http://www.scjc.state.ny.us/Legal%20Authorities/rgjc.htm. Judicial ethics emphasizes independence.

ing into a new attorney-client relationship; taking on a new file from an existing client; or taking on a personal interest, including but not limited to a financial interest. In part, because the conflict of interest of one lawyer is, as a general principle, imputed to all lawyers working in the same firm or group practice, procedures, internal databases, and software have been developed to assist large firms in identifying possible conflicts of interest. So, for example, a lawyer who marries will immediately report that change of status to his firm along with the spouse's investments, family connections, employer, and the like. In some cases, law firms have staff dedicated to monitoring conflicts of interest, including, according to one New York City law firm partner whom we spoke with, general counsel whose risk management responsibilities include conflict of interest issues. Lawyers also use letters of engagement to carefully specify which of the firm's lawyers will be working for the client on the particular matter to avoid or make more manageable any future conflict of interest.

For the first kind of conflict, the analogy with medicine is not particularly strong: physicians are not generally constrained from taking on new patients because of their loyalty to other (current or former) patients, although analogous problems concerning confidentiality may arise when one physician serves several members of the same family. The analogy becomes somewhat stronger if one thinks of a pharmaceutical company or a device manufacturer with whom a physician has a financial relationship as one "client" and one or more patients as the other "client."

The legal profession's management of the second kind of conflict—a conflict between a lawyer's personal interests and the interests of a client—could provide more direct instruction to medicine, insofar as there is a concern that physicians' financial and other relationships with industry might lead physicians to make clinical decisions that they would not have made but for those financial or other relationships.

Furthermore, the legal profession's general attitude toward conflict of interest might be instructive for medicine. Conflicts of interest are understood to be a common feature of legal practice for which the profession has developed norms, rules, and procedures. Censure attaches not to finding oneself in a position in which agreeing to represent a client would create a conflict of interest (all lawyers are in this position from time to time, even though they try to avoid it) but to agreeing to represent that client without properly addressing the conflict of interest.

Lawyers share some similarities with physicians. Until recently, many lawyers worked alone or in small group practices. Lawyers are under a strong obligation of fidelity to their individual clients; and although some clients are large companies or sophisticated and powerful individuals, many are vulnerable individuals, including people who are in trouble with the law, are victims of physical harm or abuse, or are making major decisions

that can have a lasting impact on their lives and the lives of their families (e.g., buying or selling property, making a will, or adopting a child). However, although some lawyers represent clients with a compromised decision-making ability, lawyers do not routinely deal with clients whose decision-making ability may be medically impaired.

In the United States, as in most other common-law jurisdictions, a lawyer (often called an attorney) may conduct all aspects of litigation (including court appearances); may represent clients in negotiations; may give legal advice; and may prepare contracts, wills, and other legal documents. The specific criteria for admission to the bar are set by each state: candidates must generally hold a law degree (J.D.) from an accredited law school; pass that state's bar examination; and in all but three jurisdictions, pass the Multistate Professional Responsibility Examination, which is a 2-hour-long multiple-choice test that includes questions about conflict of interest.[9]

To be accredited, American law schools are required to provide substantial instruction to all J.D. students in the values, rules, and responsibilities of the legal profession, including instruction in the identification and management of conflicts of interest.[10] Law professors themselves are subject to any conflict of interest policies of their own institutions. In keeping with the Association of American Law Schools' 2003 *Statement of Good Practices by Law Professors in the Discharge of Their Ethical and Professional Responsibilities*, law professors are obligated in publications and presentations to "disclose the material facts relating to receipt of direct or indirect payment for, or any personal economic interest in, any covered activity that the professor undertakes in a professorial capacity."[11]

To maintain the license to practice law, 41 U.S. states require completion of a prescribed number of hours of continuing legal education (CLE), and 36 of these states mandate the inclusion of professional responsibility (also called "legal ethics"), including in some states "elimination of bias."[12] Providers of mandatory CLE, which can be law schools, law firms (which offer CLE only to lawyers in-house or to outside lawyers as well), or private companies, must individually be accredited by each state's CLE accrediting authority. Mandatory CLE can be funded in a number of ways: it may be provided for a fee or it may be offered for free by the ABA, by state bar

associations, or by law firms. (One lawyer with whom we spoke noted that large malpractice firms sometimes sponsor CLE.) The lawyer or the lawyer's employer pays the fee. Providers are required to offer tuition assistance to unemployed attorneys, attorneys working in the public sector, and those in a financial hardship situation. Lawyers seem unconcerned about the prospect of commercial interests being involved with CLE—they even allow corporate sponsorship at CLE events. Of course, in general, commercial providers of CLE are not potential clients or adverse parties but simply the makers of the tools or the providers of the services that lawyers use in the course of their work.

As a result of these requirements, virtually all, if not all, U.S. lawyers have received instruction on the identification and management of conflicts of interest, and many continue to address this issue in their CLE. Because the legal profession has developed considerable case law, detailed rules (described below), and legal scholarship (two or three dozen articles per year) addressing lawyers' conflicts of interest, there is much for American law students and lawyers to learn.

Canons, Model Codes, and Model Rules

Although local bar associations began to appear in the United States in the late 19th century, most U.S. lawyers at the time were only informally controlled by reputation and peer pressure. The ABA was founded in 1878; and one of its first major initiatives became, in 1908, the Canons of Professional Ethics, developed in response to a perceived need to promote and vouch for the integrity (or reliability) of lawyers generally.[13] Initially there were 32 canons, and the number of canons eventually expanded to 47. The individual canons were fairly brief (the briefest is one sentence of two dozen words, whereas the longest is a few paragraphs). They were not accompanied by further guidance or detailed explanation, as is found in modern codes of legal ethics. Nevertheless, they were influential. By 1924, virtually every state and local bar association had adopted the canons.[14]

A number of the canons are relevant to conflict of interest, although it was the sixth canon (titled Adverse Influences and Conflicting Interests) that addressed the issue directly. Canon 6 consisted of three short paragraphs, and although it was fairly unsophisticated and incomplete, it captured the major conflict of interest issues that attorneys face even today. It attempted

[14] James M. Altman, "Considering the ABA's 1908 Canons of Ethics," *Fordham Law Review* 2003; 71: 2395–2524, at 2396, quoting Report of the Standing Committee on Professional Ethics and Grievances, *American Bar Association Report* 1924; 49: at 466, 467.

a definition of client-client conflict of interest as a conflict of obligation ("when, in behalf of one client, it is his duty to contend for that which duty to another client requires him to oppose"), identified client loyalty and confidentiality as two values threatened by conflict of interest, identified the particular problems of concurrent and subsequent representation of conflicting clients, and proposed one remedy for concurrent representation (disclosure followed by informed consent).[15] Other canons dealt with related conflict of interest issues, including a prohibition on a lawyer purchasing an interest in the subject that is a matter of litigation and a requirement that contingency fee arrangements be supervised by the court to prevent unjust charges.

Fifteen amendments to the canons (none related to Canon 6) were adopted before the ABA developed a new code, the *Model Code of Professional Responsibility*, in 1969.[16] The *Model Code* was a far more detailed document than the canons. It contained nine "canons" (described as "axiomatic norms"). These doubled as section titles. Each canon was followed by a series of Ethical Considerations and Disciplinary Rules. The Ethical Considerations were described as "aspirational in character," representing the objectives toward which all lawyers should strive. The Disciplinary Rules were, unlike the Ethical Considerations, mandatory and set "the minimum level of conduct below which no lawyer can fall without being subject to disciplinary action."

Conflict of interest was mainly addressed in Canon 5 of the *Model Code*, which states: "A Lawyer Should Exercise Independent Professional Judgment on Behalf of a Client." The first of the 24 Ethical Considerations for Canon 5 explains that

> [The] professional judgment of a lawyer should be exercised, within the bounds of the law, solely for the benefit of his client and free of compromising influences and loyalties. Neither his personal interests, the interests of other clients, nor the desires of third persons should be permitted to dilute his loyalty to his client.

The seven Disciplinary Rules describe a mix of situations in which a conflict of interest is prohibited outright and situations in which the interest is permissible only after the conflict of interest is fully disclosed to and informed consent is received from the client or clients in question.

Although the states more or less uniformly adopted the *Model Code*, it was soon abandoned.[17] In 1983, the ABA adopted a replacement. One theory about why the *Model Code* was so quickly replaced is that it mixed

[15] American Bar Association Canons of Ethics, Canon 6.

[17] Charles W. Wolfram, *Modern Legal Ethics,* West Publishing, 1986.

minimum standards of conduct permitted under the law with ethical rules intended to set higher standards and therefore was perceived as confusing ethics with law (and, in the process, reducing ethical standards).[18] In its report to the ABA recommending the adoption of a new code of professional responsibility, the Kutak Commission on Evaluation and Professional Standards cited a steady increase in concern about professional ethics, including Supreme Court cases, statutes and regulations, opinions of the ABA's Committee on Ethics and Professional Responsibility, and reports and articles, as leading it to reconsider the *Model Code*.[19] The commission ultimately concluded that amendments would not suffice to address this increased concern, and so, just 15 years after adopting the *Model Code*, the ABA replaced it with the *Model Rules of Professional Conduct*. The states were slow to adopt the *Model Rules*, although today all states but California, Maine, and New York have professional conduct rules that follow the format of the *Model Rules*. (New York still follows the *Model Code*, and California and Maine have developed their own rules.)[20]

The *Model Rules* are fairly detailed, clustered under eight headings, and accompanied by lengthy comments. The *Model Rules* most closely related to conflict of interest fall under the heading "Client-Lawyer Relationship" and are described in the following sections.

Rule 1.7. Conflict of Interest: Current Clients

Rule 1.7[21] begins with a strong statement of general principle, followed by a description of the circumstances in which the general principle does not apply. The general principle is that a lawyer "shall not represent a client if the representation involves a concurrent conflict of interest." A concurrent conflict of interest is defined as the situation in which the representation of one client will be directly adverse to that of another client (conflict of obligation) or there is a "significant risk" that representing one client will be "materially limited" by the lawyer's responsibilities to another client, a former client, or a third party or by the personal interest of the lawyer (true conflict of interest). However, the lawyer may proceed

[19] American Bar Association Commission on Evaluation of Professional Standards (Robert J. Kutak Chairman), "Model Rules of Professional Conduct: Discussion Draft," January 20, 1980. www.abanet.org/cpr/mrpc/kutak_1-80.pdf.

[20] American Bar Association website, ABA Model Rules of Professional Conduct: State Adoption of Model Rules. www.abanet.org/cpr/mrpc/model_rules.html.

[21] American Bar Association, Model Rules for Professional Conduct: Rule 1.7. www.abanet.org/cpr/mrpc/rule_1_7.html.

despite this conflict with the written informed consent of each client and provided that so proceeding (1) is not prohibited by law and (2) will not involve representing two opposing parties in litigation and (3) provided that the lawyer "reasonably believes" that he or she can provide competent and diligent representation to both clients. (The *Model Rules* define "reasonably believes" in both subjective and objective terms: the lawyer must actually believe, and the belief must be reasonable.)

Rule 1.7 is accompanied by a comment, which is 35 paragraphs long.[22] Its second paragraph describes the process that lawyers must go through under the rule: they must

> 1) clearly identify the client or clients; 2) determine whether a conflict of interest exists; 3) decide whether the representation may be undertaken despite the existence of a conflict, i.e., whether the client's consent could be an appropriate cure; and 4) if so, consult with the clients affected under paragraph (a) [any clients affected by a concurrent conflict of interest] and obtain their informed consent, confirmed in writing.

Determining whether a conflict of interest exists often involves some judgment (although the comment casts the net fairly widely to include cases both of "direct adverseness" and of "significant risk that a lawyer's ability [to act for the client] will be materially limited"). The key judgment here, however, is whether the conflict is "consentable"—bearing in mind that the presumption is that a lawyer must not represent opposing parties in litigation or where prohibited by law. The rationale for the division between consentable and nonconsentable seems to be that some conflicts of interest are too risky for the client or profession—for example, the lawyer might appear to a reasonable outsider to be taking egregious advantage of the client for the lawyer's personal benefit (even though the lawyer is not).

Paragraph 14 of the comment for Rule 1.7 begins by noting that although clients may ordinarily consent to representation notwithstanding a conflict, "some conflicts are nonconsentable, meaning that the lawyer cannot properly ask for . . . agreement or provide representation on the basis of the client's consent." Although it is long, the comment provides little additional guidance on how to determine whether a conflict is consentable other than to note at Paragraph 15 that representation is prohibited if the lawyer "cannot reasonably conclude that [he or she] will be able to provide competent and diligent representation." The next two rules provide more specific guidance.

[22] American Bar Association, Model Rules for Professional Conduct: Rule 1.7 Comment. www.abanet.org/cpr/mrpc/rule_1_7_comm.html.

Rule 1.8. Conflict of Interest: Current Clients: Specific Rules

Rule 1.8[23] adds to the general principles contained in Rule 1.7 10 classes of conflict of interest situations, some of which may be resolved with the consent of the client (and sometimes subject to other protective measures) and some of which cannot be resolved even with consent. Rule 1.8 therefore helps lawyers to determine when a conflict may be consentable.

Conflict of interest situations that are not consentable include

- soliciting or preparing an instrument to receive a substantial gift from a client unless the client is a relative,
- negotiating literary or media rights that would substantially rely on information relating to the representation,
- providing financial assistance to a client for litigation except where the client is indigent or where litigation costs will be repaid under a contingency agreement or lien, and
- having sexual relations with a client unless the sexual relationship preceded the attorney-client relationship.

Conflict of interest situations that are in principle consentable (provided that other conditions are met, such as advising the client of the desirability of seeking independent legal counsel) include

- entering into a business transaction with a client,
- knowingly acquiring an ownership or other interest that is adverse to a client,
- using information about one client to another client's disadvantage,
- accepting compensation for representing a client from a third party, and
- representing two or more clients in an aggregated settlement or agreement (for example, both parties in a friendly divorce).

In such situations, provided that full disclosure is followed by valid informed consent, a lawyer might reasonably be able to argue that an "arm's-length transaction" took place (something not possible in the nonconsentable situations), that is, that the client was fully able to look after its own interests without relying on the lawyer.

[23] American Bar Association, Model Rules for Professional Conduct: Rule 1.8. www.abanet.org/cpr/mrpc/rule_1_8.html.

Rule 1.9. Duties to Former Clients

Rule 1.9[24] provides that a lawyer should not agree to represent a person if the lawyer has previously represented a client in the same or a related matter and the interests of the new person are materially adverse to the interests of the former client, unless the lawyer has the written informed consent of the former client. (The requirement of "written" consent assures both a record, in case of a later dispute, and more formality at the time that consent is given.) The same rule applies when a lawyer knowingly takes on a new client whose interests are materially adverse to the interests of a former or a current client of that lawyer's former firm and about whom the lawyer has acquired protected information. This rule is designed to respond to lawyer mobility and to ensure that lawyers do not bring with them conflicts of interest from their previous firms without the consent of the former client.

In contrast to the first two parts of Rule 1.9, which allow the lawyer to represent the new client with the informed consent of the former client, the third part of Rule 1.9 (which concerns loyalty rather than conflict of interest) provides that information about former clients cannot be used to the disadvantage of the former client unless use of that information is otherwise allowed in the rules (that is, loyalty to the client continues after the representation ends). Like Rule 1.8, therefore, Rule 1.9 distinguishes between conflict of interest situations that are low risk enough to be resolved by informed consent and those that are nonconsentable because the risk is too high to be resolved by disclosure and consent or the problem is more serious than conflict of interest (conscious disloyalty).

Rule 1.10. Imputation of Conflicts of Interest: General Rule

Rule 1.10[25] is extremely important today when so many lawyers practice in large firms rather than as sole practitioners. Under the rule, the conflicts of interest of one lawyer in a firm are imputed to all lawyers in the firm: "a firm of lawyers is essentially one lawyer for purposes of the rules governing loyalty to the client."[26] The rule prohibits a member of a law firm from knowingly representing a client that any one of them practicing alone would be prohibited from representing under Rules 1.7 and 1.9, unless the prohibition is based on a personal interest of the lawyer and "does

not present a significant risk of materially limiting the representation of the client by the remaining lawyers in the firm." Disqualification under the rule may be waived with the consent of the affected client (and subject to the prohibitions contained in Rule 1.7).

Rule 1.10 is strict and can be very burdensome for large law firms. Law firms have devised methods for "screening" lawyers within firms as a way of managing conflicts of interest (discussed in more detail below), but it is important to note that screens (which in other professions or arenas might be described as "firewalls") are not discussed in the *Model Rules*, except in limited situations involving former government lawyers.

In addition to these codes of ethics, case law has developed over several centuries to deal with lawyers' conflicts of interest (under various names). In the United States, this case law is helpfully summarized in the American Law Institute's *Restatement of the Law Governing Lawyers*.[27] Chapter 8 of that document analyzes conflicts of interest in general, including conflicts between a lawyer and a client, among current clients, between a lawyer and a former client, and because of the lawyer's obligation to a third person. This case law complicates matters for lawyers, since they must follow both the rules (explicitly or implicitly) laid down in those cases and the ABA's ethical rules. At the same time, the case law effectively addresses the malpractice liability of lawyers who fail to resolve a conflict of interest adequately and provides civil remedies for this malpractice, including damages paid to harmed clients or third parties and disqualification from continuing to represent a client in a particular matter.

The combined effect of the case law described in the restatement of the law governing lawyers and the ethical rules of each jurisdiction is that lawyers who fail to avoid conflicts of interest or to manage them adequately can be sued for malpractice, forced to pay monetary damages, disqualified by a judge from representing a client, or some combination of these. They can also lose their fee or receive only a reduced fee and face disciplinary action by the state bar (including disbarment). Although conflicts of interest are, in the first instance, to be identified by individual practitioners, local bars and the courts can become involved at later stages if those conflicts have not been properly managed. In this way, lawyers rely on self-regulation backed by the threat of professional and legal sanctions.

In fact, few lawyers are disciplined and even fewer are disbarred. A 2006 ABA survey found that of over 120,000 complaints filed against lawyers on any issue, only 3.5 percent led to formal discipline and less than 0.5

[27] Charles W Wolfram (ed.), *Restatement of the Law Third, The Law Governing Lawyers*, American Law Institute, 2000.

percent led to disbarment.[28] Although data on the numbers of allegations or findings of improper management of conflict of interest are not available at the federal level, some data are available at the state level. For example, between 2002 and 2006, sanctions for conflict of interest were imposed in only 11 percent of 530 cases, only 1 of which resulted in revocation of the license to practice (other sanctions were suspensions and reprimands).[29]

Conflict of Interest Management: Key Issues for Lawyers

Although the bar's system of conflict of interest management is well developed, it is not without its critics or its thorny issues. For example, despite the large number of cases, articles, and the detailed codes or rules, the legal profession's management of conflict of interest is still described as "abstruse," "arcane," and "intractable."[30] According to law professor Kevin McMunigal, however, the primary problem in the law's conflict of interest doctrine is a failure to recognize the regulation of conflict of interest as a kind of risk management and not prevention of direct harm. This failure leads the legal profession to use harm rules, which punish lawyers who harm clients, and risk rules, which aim to prevent harm to clients indirectly by keeping lawyers out of risky situations or by otherwise managing conflicts of interest but without engaging the all important question: How much risk is too much?

McMunigal gives the example of a lawyer in a high-profile criminal case who early on accepts a lucrative book deal to write about the case. When the prosecution offers to settle the case (an option, McMunigal adds, that would clearly be in the client's best interests), the lawyer advises her client to reject the settlement. McMunigal argues that the risky situation of the book deal (with the temptation being to take the case to trial to ensure publicity and probably help future book sales) probably led the lawyer to give bad legal advice (which would be harmful if it was followed). However, as McMunigal sees it, the legal profession uses the language of conflict of interest to describe and address both the risky situation and the harmful action. If the legal profession could more clearly separate harm rules—for example, rules against lawyers providing bad legal advice or against lawyers entering into unfair business deals with their clients—from risk rules—for example, rules prohibiting a lawyer from preparing an instrument by which

the lawyer will receive a gift from the client or rules against accepting book deals based on cases—then, McMunigal argues, the legal profession would also avoid confusion about the goals of and justification for each kind of rule.[31]

McMunigal suggests that conflict of interest rules should be understood as being restricted to governing risky situations, leaving rules against breaching confidentiality or against providing incompetent advice to deal with situations in which actual harm has resulted (and in which the causal chain can be proved). In the medical context, conflict of interest rules could therefore focus on identifying and governing situations in which the risk of tainted judgment is considered unacceptably high. The rules invoked to deal with actual harm to patients (other than harm to trust in their physicians and the profession in general) would allege not conflict of interest but inappropriate practice, bias, breach of confidentiality, or the like. Another consequence of sharply distinguishing between risk and actual harm would be to make unnecessary the distinction between "actual" and "potential" conflicts of interest, which McMunigal considers to be a distinction of little practical use.

In his analysis of the legal profession's management of conflicts of interest, law professor Robert Lawry focuses on a different kind of problem.[32] He sees a gradual lessening of professional standards to allow for the greater mobility of lawyers, which is at least partially justified by an appeal to the increased sophistication of some clients. One reason for this reduction in standards is, as mentioned above, the mixing over time of ethics (a guide to good professional behavior) and law (minimum standards by which to police the profession). Another reason is the reality of modern legal practice, where lawyers move from town to town and firm to firm. Yet another reason that exceptions to conflict of interest rules and methods for managing conflicts of interest have developed is to allow medium to large firms to serve many clients, some of whom will, from time to time, have both opposing interests and an interest in relying on lawyers who know them.

---

[31] Consider the debate over financial conflicts of interest in biomedical research: there is some confusion about whether the goal of conflict of interest rules is to identify cases of actual harm (usually bias) or to reduce the risk of harm (Shira Lipton, Elizabeth Boyd, and Lisa Bero, "Conflicts of Interest in Academic Research: Policies, Processes, and Attitudes," *Accountability in Research* 2004; 11(2): 83–102). The parties can end talking past each another, with one side asking for proof that harm was caused in this or that case by a conflict of interest before agreeing to the rules and the other side appealing to intuitive ideas about risk or to data showing correlations between conflicts of interest and bad outcomes in aggregates to justify prohibitions or other measures.

[32] Robert P. Lawry, "The Law and Ethics of Lawyers' Conflicts of Interest," in Thomas H. Murray and Josephine Johnston (eds.), *Ethical Issues in Financial Conflicts of Interest in Biomedical Research*, Baltimore (MD): Johns Hopkins University Press, forthcoming.

Screens, Chinese Walls, and Cones of Silence

One major mechanism for managing conflicts of interest with concurrent clients is through the use of screens (also known as "firewalls," "Chinese walls," or "cones of silence"). Screens are mechanisms by which lawyers working on one matter are prohibited from certain kinds of communication with lawyers in the same firm working on a conflicting matter. The prohibition is sometimes augmented by placing the lawyers in separate locations (on different floors or in different buildings), controls on e-mail and file access, and the like. Some screens are simply matters of honor; some involve real walls. Screens cannot change a nonconsentable conflict into a consentable one. Instead, screens are used "to encourage clients to consent to a loyalty conflict."[33]

Lawry sees screens as further evidence of erosion in lawyers' conflict of interest standards. Lawyers were introduced to the idea of screens in 1975 by Formal Opinion 342 of the ABA's Standing Committee on Ethics, which argued that former government lawyers should be permitted to work for a firm doing business with the government if they are screened within the firm from files that they worked on while they were in government. Without such screens, it was argued, "good lawyers would avoid government work, to the detriment of the common good." This principle, which was developed for government lawyers and which is discussed only in the *Model Rules* (and comments) in reference to government lawyers, is now routinely extended to private lawyers. Lawry reports that 22 of 51 jurisdictions allow screening without the consent of the former client.[34] Screens have also received some recognition in the courts and are endorsed in the restatement of the law governing lawyers as a way of dealing with conflicts created by lawyers switching firms. Reasonable people will likely continue to disagree about whether screens are a sign of eroding legal ethics or evidence that legal practitioners are both committed to legal ethics and capable of creating effective management systems. Nevertheless, the debate shows that lawyers are engaging with the fundamental question of how to balance the risks of conflict of interest in such situations against the benefits of tolerating the conflict if it is properly managed.

ACCOUNTANTS

As in other professions, much work in accounting can be conducted by uncertified (or unlicensed) individuals, but some accounting functions

[33] Susan R. Martyn, "Visions of the Eternal Law Firm: The Future of Law Firm Screens," *South Carolina Law Review* 1994; 45(1): 937–959.

can be carried out only by a certified accountant. Certified accountants in the United States are: (1) CPAs, who are licensed by their state to provide auditing and attestation services; (2) certified internal auditors, who mostly provide their services directly to their employers; or (3) certified management accountants and certified business accountants, who, although they deal with the public, cannot audit public companies. Each of these certifications is issued by a professional body that maintains a code of ethics and that examines applicants on the basis of that code of ethics as well as on the basis of their technical skills. Individuals may carry more than one certification, but only licensed CPAs can perform the mandatory audits of publicly traded U.S. companies. CPAs are the focus of this discussion because of their prominent public role and their recent struggles to manage conflicts of interest.

Like lawyers, CPAs have clients—the companies that hire them to prepare their financial statements—but like architects and engineers and unlike lawyers, CPAs are wary of going too far in acting in their clients' interests. Lawyers, particularly during litigation, must primarily attend to their client's interests, leaving it to opposing counsel or the judge to find the flaws in their argument or weaknesses in the client's case. CPAs, in contrast, are obliged to put the public interest first when they perform an audit or attestation; they are not allowed to withhold or ignore negative information; indeed, part of their job is to seek out such information.[35] The rationale for privileging the public interest is that shareholders and other investors rely on the work of CPAs when they make decisions about whether and how to invest their money. Thus, although a company will engage and pay a CPA (often through an accounting firm) to perform its audits, both the company and the public are the beneficiaries of the CPA's work. The public benefits from having financial information that it can rely on. The company benefits from the public's ability to trust the company's financial reports.

Unlike a physician's patients, the accountant's clients are frequently sophisticated individuals or businesses; few are physically or mentally compromised. Although the matters entrusted to the accountant are seldom trivial, they are not literally life and death.

[35] That said, they are not generally required to blow the whistle on their clients by reporting fraud to outside agencies (Leonard J. Brooks, "Conflict of Interest in the Accounting Profession," in Michael Davis and Andrew Stark (eds.), *Conflict of Interest in the Professions*, New York: Oxford University Press, 2001). They are only required by law to report fraud to the client's senior management and its audit committee, a subcommittee of the client's board of directors that itself is under strict reporting requirements (Section 10A(1)(b) of the Securities Exchange Act of 1934 and American Institute of Certified Public Accountants, Statement on Auditing Standards: No. 99, Considerations of Fraud in a Financial Audit Statement).

Licenses and Professional Membership

As in other professions, professional accounting societies were developed to ensure clients that people holding themselves out as accountants met minimal levels of education, competence, and ethical conduct.[36] Today, professional accounting societies do not license accountants—that function has been taken over by the state-designated accountancy boards—but the professional societies provide guidance on many issues, from technical accounting standards to ethics. Clients, who rely on accountants to provide specialized services and advice, may find some reassurance in the imprimatur of good standing in a professional society.

AICPA is a voluntary association. Although all CPAs must be licensed by their state boards of accountancy (or the equivalent), they are not obliged to be members of their state or national CPA organizations. Membership in good standing of the state or national CPA organization can, however, enhance the reputation of the CPA. (AICPA provides marketing tool kits to its members.)

The specific requirements for the CPA license vary somewhat from state to state, but all states require that individuals pass the Uniform Certified Public Accountant examination, which was developed and which is maintained by AICPA and which is administered by the National Association of State Boards of Accountancy. Questions about professional ethics are included in the Uniform Certified Public Accountant examination and are based on AICPA's *Code of Professional Conduct*.

Many state licensing boards require continuing professional education (CPE) that includes ethics or professional conduct. These state boards prescribe CPE course requirements, but the courses are offered to CPAs by approved companies (sometimes called "sponsors") for a fee. Some attention is paid to the independence of the CPE programs and their sponsors. In New York, for example, CPE can be offered only by sponsors that have been approved by the New York Department of Education, which requires sponsors to have a "direct interest in offering courses on a regular basis" and will not approve "programs devoted to the promotion of particular products or services" or "[i]nsurance, pension, investment, software and other offerings primarily promotional or informational in nature."[37]

CPE is offered by a range of sponsors, including universities and private companies.[38]

Accountancy After Enron

In addition to understanding and following AICPA's *Code of Professional Conduct* (described in more detail below), CPAs need to be aware of and follow the rules of their state board of accountancy; the ethics standards of their state CPA organization (if they are members); any applicable state laws; and any applicable federal laws, notably, the Public Company Accounting Reform and Investor Protection Act of 2002.[39] This act, commonly known as the Sarbanes-Oxley Act, was passed in response to a number of corporate and accounting scandals in the late 1990s and early 2000s. Before passage of the act, the largest accounting firms had diversified their practices to the extent that audits were a small part of the services that they provided to their clients. Considered key to gaining insight into the client's business, audit prices steadily declined while other services increased in profitability. As a business school professor at the University of Saskatchewan puts it, "Clients became sophisticated purchasers, shopping around for the best deal and putting intense pressure on audit prices, and thus on profits . . . some companies [clients] began to resort to a practice known as 'opinion shopping.'"[40] Accounting firms were soon offering consulting services to audit clients that brought in far more than the audit fee, and therefore, "the auditors did not want to do anything to rock the boat with clients, potentially jeopardizing their chief source of income."[41]

This tension between auditing and consulting was identified and critiqued before the Enron scandal, but it was only after the collapse of Enron and WorldCom that practices and codes of conduct changed to address it. Boyd calls Enron "the 'smoking gun' evidence, indicating that the profession had reached a stage where commercial interests simply overwhelmed allegiance to professional integrity." Policy makers were not content to leave it to accounting firms or AICPA to address the issue. They chose to pass legislation—the Sarbanes-Oxley Act—to restore the reliability of the public company audit process.

Subject to certain preapprovals, Section 201 of the Sarbanes-Oxley Act prohibits auditors from providing a number of other services contemporaneous to the audit, including bookkeeping, management functions,

[41] Arthur Levitt, *Take on the Street*, New York: Pantheon Books, 2002.

investment advice, investment banking services, and legal services. The act also creates the Public Company Accounting Oversight Board (PCAOB) to oversee CPA practice in relation to public companies. Under Section 103 of the act, PCAOB has established standards and rules on a variety of issues, including ethics, that apply to registered public accounting firms preparing and issuing audit reports as required by the act or the rules of the Securities and Exchange Commission.

PCAOB's conflict of interest rules are designed to preserve the independence of the accounting firm.[42] Rule 3520 states: "a registered public accounting firm and its associated persons must be independent of the firm's audit client throughout the audit and professional engagement period." Rules 3521, 3522, and 3523 describe situations in which an accounting firm cannot be considered independent, for example, if the firm provides a service or product to the audit client for a contingent fee or a commission, if the firm provides assistance in planning or tax advice on certain types of potentially abusive tax transactions to an audit client, or if the firm provides any tax services to certain persons in a financial reporting oversight role at an audit client or to immediate family members of such persons.

Violation of the PCAOB rules can lead to an investigation by PCAOB. Following a hearing, sanctions can be imposed, including (1) revoking a firm's registration; (2) barring an individual from participating in audits of public companies; (3) monetary penalties; and (4) remedial measures, such as training, the implementation of new quality control procedures, or the appointment of an independent monitor.[43] PCAOB's website reports that 3 of the 17 disciplinary proceedings before PCAOB over the past 3 years have found "independence" violations.

There has been some criticism that the post-Enron measures are too burdensome,[44] with others countering that the measures fail to do enough to end auditor-client "coziness."[45] Either way, this legislation and accompanying rules and sanctions serve as a cautionary tale. They installed the external regulation of a profession that apparently had not sufficiently regulated its own conflicts of interest. Since the Sarbanes-Oxley Act was passed, AICPA and state CPA societies have strengthened their codes of conduct, an example of a change in law forcing a tightening of ethical standards.

AICPA Code of Professional Conduct

The current version of the AICPA *Code of Professional Conduct*[46] emphasizes independence and objectivity. The AICPA *Code of Professional Conduct* is divided into principles and rules. The six principles are expressed in a sentence or two. Each principle is clarified by up to five subparagraphs. The dozen rules that follow the principles are also expressed in one or two sentences but are followed by more detailed guidance in the form of Interpretations of Rules of Conduct and Ethics Rulings (rather like the American Medical Association's [AMA's] Opinions).

AICPA's professional ethics committee adopted Interpretations of Rules of Conduct "after exposure to state societies, state boards, practice units and other interested parties." The Interpretations of Rules of Conduct are intended "to provide guidelines as to the scope and application of the Rules but are not intended to limit such scope or application." Ethics rulings are formal rulings made by AICPA's professional ethics committee applying the rules and their interpretations to a particular set of facts. AICPA members who depart from ethics rulings in similar circumstances will be "requested to justify such departures."[47]

Two of the Code's principles bear on conflict of interest. The first, titled Integrity, states that "to maintain and broaden public confidence, members should perform all professional responsibilities with the highest sense of integrity" and includes a reference to observing the principles of objectivity and independence in its final subparagraph. The other relevant principle, titled the Public Interest, requires members "to act in a way that will serve the public interest, honor the public trust, and demonstrate commitment to professionalism." Acknowledging that members may encounter conflicting pressures, this principle advises that, when resolving such conflicts, members recall that when they "fulfill their responsibility to the public, clients' and employers' interests are best served."[48]

Although these two principles clearly bear on conflict of interest, it is the fourth principle (titled Objectivity and Independence) that addresses conflict of interest most directly. It states: "A member should maintain objectivity and be free of conflicts of interest in discharging professional re-

[46] The American Institute of Certified Public Accountants, AICPA Code of Professional Responsibility. www.aicpa.org/About/code/index.html.

sponsibilities. A member in public practice should be independent in fact and appearance when providing auditing and other attestation services."[49]

The general rule, therefore, is that all CPAs should always be free of conflicts of interest. An even higher standard is set for CPAs in public practice. That is, when a CPA is performing certain services in public practice, the CPA should maintain objectivity in appearance as well as in fact. Public practice is defined as the performance for a client of accounting, tax, personal financial planning, litigation support, and other professional services for which practice standards are promulgated by AICPA. (The closest medical equivalent to a CPA's public practice is a physician's publication of research or the testimonials or other public statements that an individuals makes as a physician.)

Four subparagraphs follow this principle. The first discusses, in a fairly philosophical way, objectivity (describing it as "a state of mind" and imposing the obligation to be "impartial, intellectually honest, and free of conflicts of interest") and then independence ("precludes relationships that may appear to impair a member's objectivity in rendering attestation services"). After noting the variety of roles that an accountant might play in society, including teaching, the second subclause states: "Regardless of service or capacity, members should protect the integrity of their work, maintain objectivity, and avoid any subordination of their judgment." The principle is thus fairly strict: CPAs should at no time enter into relationships that might even appear to impair their objectivity. The third subclause focuses on accountants working in public practice, stating that to protect their independence (the appearance of objectivity), they should be continually assessing "client relationships and public responsibility" and "should be independent in fact and appearance." The effect of this subparagraph is to require constant vigilance of the possible impact of interactions with clients on the CPA's (actual and apparent) commitment to the public interest. The fourth subclause applies to members not in public practice (e.g., members employed by a company rather than acting as an external accountant or auditor). That subclass concedes that CPAs not in public practice "cannot maintain the appearance of independence" but nevertheless imposes on them "the responsibility to maintain objectivity in rendering professional services."

More detail in the form of rules, interpretations, and ethics rulings follow at Sections 101 (Independence) and 102 (Integrity and Objectivity).[50]

[49] The American Institute of Certified Public Accountants, AICPA Code of Professional Responsibility: Section 55, Article IV, Objectivity and Independence. www.aicpa.org/About/code/et_55.html.

[50] The American Institute of Certified Public Accountants, AICPA Code of Professional Responsibility: Section 100, Independence, Integrity, and Objectivity. www.aicpa.org/About/code/sec100.htm.

Section 101 begins with the rule that a member in public practice shall be independent according to the standards set by state boards, state CPA institutes, the U.S. Securities and Exchange Commission, and PCAOB, among others. The interpretation for this rule then describes the circumstances under which independence will be considered impaired. Situations of impairment include the following: when the accountant, during the period of professional engagement, holds or commits to acquiring a financial interest in the client; when the accountant has a loan to or from the client or in some circumstances when the accounting firm, one of its partners, or a partner's immediate family members hold an ownership stake in the client; and when the accountant's firm or a partner or employee of the firm was simultaneously a director, officer, or employee of the client. (The last prohibition applies not simply during the period of the professional engagement but during the whole period covered by the financial statements being prepared by the accountant.) When in doubt about whether a particular circumstance might cause independence to be questioned, the section asks that members "evaluate whether that circumstance would lead a reasonable person aware of all the relevant facts to conclude that there is an unacceptable *threat* to the member's and the firm's independence" (emphasis added).

Fourteen additional interpretations follow, and that number is far too many to cover in any detail here. It will be enough to note here that the net cast is fairly wide. Section 101 captures a number of situations involving the accountant; the firm; colleagues; family members; close relatives; or current or previous financial, employment, ownership, or management relationships with the client. The interpretations also differentiate between direct financial interests (such as ownership and investment interests) and indirect financial interests, including some holdings through mutual funds. In one of the Ethics Rules accompanying Section 101, the question of the CPA's acceptance of gifts or entertainment from a client is posed. The answer is that the acceptance of gifts or entertainment from a client that the CPA is auditing will be considered to impair objectivity, unless the value is "clearly insignificant to the recipient." The ethics ruling is less restrictive when the client is not an "attest client" (i.e., one for whom the CPA performs auditing or other attestation services), although even in such cases the CPA is required to assess whether accepting the gift is reasonable, given the nature, value, timing, and frequency of the gift.

The overall aim of the independence rule and its interpretations and ethics rulings at Section 101 is to ensure that audits of companies will be carried out by accountants and accountancy firms who provide no other financial services to the company, are not investors in or directors of the company, do not and have not recently worked for the company, have no other financial or other ties to the company, and are otherwise free of any appearance suggesting to a reasonable person a loss of objectivity. Despite

its detail, this section has been criticized for failing to address one particular threat to independence (and objectivity): the significance of the client company's audit fees to the bottom line of the accountant or the firm.[51] One observer points out that Arthur Andersen's Houston, Texas, office received $1 million per week from Enron while it was auditing the company: "[The] livelihoods of several audit partners and several hundred audit firm employees depend[ed] on keeping a client happy."

Section 102 (Integrity and Objectivity) is far briefer than Section 101 and applies to all CPAs in all of their work (i.e., not simply to CPAs performing audits). It begins with the rule that "in the performance of any professional service a member shall maintain objectivity and integrity, shall be free of conflicts of interest, and shall not knowingly misrepresent facts or subordinate his or her judgment to others." Although the rule is concerned with the misrepresentation of fact as well as conflict of interest, the interpretations for the rule offer a definition of conflict of interest: "a conflict of interest may occur if a member performs a professional service for a client or employer and the member or his or her firm has a relationship with another person, entity, product, or service that could, in the member's professional judgment, be viewed by the client, employer, or other appropriate parties as impairing the member's objectivity." Note that the relationship need not be financial or familial, and it need not actually impair the CPA's objectivity—it is enough that it could, in the member's judgment, appear to impair his or her objectivity.

In contrast to Section 101, which provides no way to manage the impairments to independence that it covers, Section 102 suggests that disclosure and consent may be acceptable ways to manage conflicts of interest "if the *member* believes that the professional service can be performed with objectivity, and the relationship is disclosed to and consent is obtained from such client, employer, or other appropriate parties" (emphasis added). The interpretation explicitly states that concern about independence in certain professional engagements, such as audits and reviews, as expressed in the previous rule (Section 101), cannot be addressed by disclosure and consent. The discussion ends with an explicitly nonexhaustive list of situations that ought to raise independence concerns, including when the CPA has a significant financial interest in or is on the management of a company that is a major competitor of the client for which he or she performs management consulting services, when the CPA is asked to perform litigation services for a case filed against one of his or her clients, or when a CPA provides services for several members of the same family with opposing interests.

[51] David Cotton, "Fixing CPA Ethics Can Be an Inside Job," *Washington Post*, October 20, 2002. P. B2.

These are all situations in which the usual public reliance on the auditor's work is absent.

Enforcement of Ethics Rules

The AICPA *Code of Professional Conduct* focuses on the impact of existing and preexisting relationships (whether of the accountant, firm, colleagues, and sometimes, members of the family) on the accountant's objectivity and independence. Objectivity and independence are particularly protected when the accountant is auditing a client for the public's benefit. When offering any service except external auditing, a CPA might be able to disclose a conflict of interest to the client and proceed with the client's consent, but this option is simply not available in a public audit (or other attestation) situation. The reason for the focus on independence from clients (a matter of appearance), from the CPA's personal interests, and from the interests of the CPA's firm, colleagues, and family during audits (and other attestation services) in particular is that a CPA performing an external audit has a primary obligation to the public. Indeed, the second principle in the *Code of Professional Conduct*, titled The Public Interest, states that the public relies "on the objectivity and integrity of certified public accountants to maintain the orderly functioning of commerce."

The rules and practices of CPAs, therefore, are fairly strict when it comes to preserving independence and avoiding even the appearance of conflict of interest. It is important to note, however, that like architects and engineers but unlike lawyers, accountants are able to work for competing clients, often but not always with the knowledge and consent of both parties.[52] The rationale for this difference is that accountants are able to perform an audit of one client without disclosing (or even relying on) information about the other. It would be much harder for a lawyer to adequately represent two competing clients without using the confidential information of one against or in favor of the other.

The preamble to the AICPA *Code of Professional Conduct* neatly describes how it is enforced: "Compliance with the *Code of Professional Conduct* . . . depends primarily on members' understanding and voluntary actions, secondarily on reinforcement by peers and public opinion, and ultimately on disciplinary proceedings, when necessary, against members who fail to comply with the Rules."

Members of AICPA are on notice that they must be prepared to justify any departure that they make from the *Code of Professional Conduct*.

[52] Leonard J. Brooks, "Conflict of Interest in the Accounting Profession," in Michael Davis and Andrew Stark (eds.), *Conflict of Interest in the Professions*, New York: Oxford University Press, 2001.

AIPCA's Professional Ethics Executive Committee interprets and enforces the AICPA *Code of Professional Conduct*. The committee investigates allegations of unethical conduct by both its members and the members of almost all state CPA organizations through its Joint Ethics Enforcement Program (JEEP).[53] JEEP has existed since the 1970s and was created in recognition of the fact that the codes of many state CPA societies are identical or similar to the provisions of the AICPA *Code of Professional Conduct* and that it is common for a CPA to be a member of both AICPA and one or more state societies. JEEP therefore provides an efficient mechanism for enforcing ethics rules consistently across the United States.

Violations of the *Code of Professional Conduct* can result in a CPA being expelled, suspended for a period of 1 or 2 years from AICPA or from the local CPA society, directed to complete specified CPE courses, or directed to take other action (e.g., submit subsequent work papers for continued monitoring). All decisions to expel or suspend a CPA are made public through publication on AICPA's website. Very few of these decisions (just 4 of over 150) during the past 3 years included a finding of a breach of the rules regarding independence. AICPA can also publicly admonish a member who has violated the *Code of Professional Conduct*. AICPA's ethics committee can also conclude, upon investigation, that there is no evidence of a violation of the *Code of Professional Conduct* and therefore dismiss the case or simply close a case for lack of evidence or some other reason.[54]

The enforcement mechanisms of suspension, expulsion, and public admonishment seem designed to place the public and colleagues on notice that the CPA does not comply with the *Code of Professional Conduct* and to publicly embarrass the CPA, whereas requiring completion of CPE courses or submitting reports and work papers seems to aim to reeducate the CPA. Because a CPA does not need to be a member of AICPA or a state CPA organization, a finding of violation of AICPA's *Code of Professional Conduct* is not itself sufficient to withdraw the CPA's license to practice. Only the state licensing boards can suspend or revoke a CPA's license.

One important lesson from the recent history of public accountancy is that a failure to address conflicts of interest led to federal regulation of conflict of interest in one important aspect of CPA practice: the auditing of publicly listed companies. Investor confidence in the objectivity and independence of auditors and therefore in the truthfulness of public companies'

[53] The American Institute of Certified Public Accountants, Professional Ethics Executive Committee, Fact Sheet 2004–2005. www.aicpa.org/download/ethics/ethics-committee-fact-sheet.pdf.

[54] The American Institute of Certified Public Accountants website, Ethics Enforcement. www.aicpa.org/About/code/sec100.htm.www.aicpa.org/Professional+Resources/Professiona+Ethics+Code+of+Professional+Conduct/Professional+Ethics/Ethics+Enforcement/defin_sanction.htm.

financial statements was considered an important enough goal—given the huge financial stakes involved—to warrant federal legislation and the establishment of a federal oversight body, the PCAOB. A second important lesson is that maintaining objective and independent judgment is not easy. Accountants primarily maintain their objectivity by avoiding most situations that present a conflict of interest. They also maintain their independence by avoiding most situations that could reasonably appear to present a conflict of interest.

ARCHITECTURE

During the decade and a half before World War I, AMA organized medicine as a modern profession. Among the milestones in that process were not only the rethinking of medical education (set forth in the 1910 Flexner Report) but also the abandonment in 1903 of AMA's mandatory *Code of Ethics* of 1847 for the "suggestive and advisory" *Principles of Medical Ethics*. That was followed in 1912 by the abandonment of the 1903 principles for another code (with the same name) binding on all physicians (and surgeons). At about that time (1909), the American Institute of Architects (AIA) adopted its first code of ethics. That code applied only to members of the organization and not to all architects, but the code (like AMA's 1847 code) was binding on all architects. The AIA kept this feature when it adopted a new code in 1977, one organized—like the ABA's 1969 code (which was to be abandoned soon after)—into canons (broad statements of principle), ethical standards (more specific goals that AIA members should aspire to), rules (mandatory standards, the violation of which would justify formal discipline, including expulsion from the AIA), and commentary (when necessary to avoid a common misinterpretation of a rule).[55]

The 1909 AIA code reached all architects, not just AIA members, through its adoption by state licensing boards as local standards of practice. That simple arrangement ended in the 1970s, when the courts declared the AIA's code to be an unreasonable restraint on trade. While the AIA was rewriting its code to avoid another lawsuit (a process that did not end until 1990), the National Council of Architecture Registration Boards (NCARB) wrote its own code.[56]

Because the states' licensure of architecture is generally similar to the states' licensure of accountants (and, in some states, lawyers), continuing education requirements are also similar. Courses must be accredited to satisfy the continuing education requirements. The AIA itself offers some online courses that satisfy continuing education credit. Some of these courses

[55] See www.aia.org/SiteObjects/files/codeofethics.pdf.
[56] See www.architects.org/emplibrary/NCARB.pdf.

are now prepared by suppliers.[57] So far, supplier-prepared courses do not seem to be a problem. One reason that they are not may be that architects' specifications (the equivalent of a physician's prescription) typically either state a generic requirement or take the form "brand *x* or its equivalent." Another reason that supplier courses are not a problem may be that they do not include a trip to some ideal location, lavish entertainment, or other gifts. The course itself must be valuable enough to repay architects for their time and for lost opportunities to take other courses.

NCARB on Conflict of Interest

Architects resemble physicians, lawyers, and accountants in not being able to practice (that is, advertise, sign drawings, or otherwise publicly present themselves as architects) without registering as one (that is, being given a state license to practice). Beginning in 1919, registration boards have maintained a nonprofit group to provide a number of services to the profession: a standardized test for admission into the profession, standards for work experiences that a new graduate of an accredited architectural program should have before licensure (Intern Development Program), self-administered continuing education courses, and so on. NCARB's code of ethics (*Rules of Conduct*) is just one of these services. Adopted in 1977 (and amended since), the *Rules of Conduct* are designed to provide hard-edged rules for discipline (once a state board adopts them). Besides the nominal "Rules"—five titles numbered with Arabic numerals—the code includes (1) actual rules under each rule (numbered with a decimal), (2) a brief commentary after most of these rules, and (3) a long introduction (40 percent of the entire 10-page code). Although the NCARB code does set a somewhat lower standard than the (shorter) AIA code, it generally does so by silence rather than by providing a formal rule significantly different from the corresponding AIA rule. The AIA issues ethics opinions much as AMA does; NCARB does not. A state registration board may, however, issue an opinion as part of disciplinary action against a particular architect.

Conflict of interest is plainly important in the practice of architecture. The second of the five major divisions in NCARB's *Rules of Conduct* is titled Conflict of Interest; the third major division, although it is titled Full Disclosure, is in part (Rule 3.1) about responding to conflict of interest. The other divisions of the code—Competence (Division 1), Compliance with Law (Division 4), and Professional Conduct (Division 5)—have no connection with conflict of interest.

The overall strategy in these provisions is clear. Conflict of interest

[57] See, for example, www.gp.com/build/paperless/education.html (a course offered by Georgia-Pacific).

should generally be avoided, but when avoidance is not possible or at least not reasonable, the conflict must be fully disclosed to all appropriate parties and their consent must be won before the architect can proceed. Interestingly, the term "conflict of interest" is not used in any of the specific rules; its definition is, in effect, the rules under that title. All of the relevant rules (including Rule 3.1) are (primarily) concerned with financial interests. There are four rules under Rule 2, Conflict of Interest.

Rule 2.1 applies to ordinary compensation for services. An architect "shall not accept compensation for services from more than one party on a project unless the circumstances are fully disclosed to and agreed to . . . by all interested parties." Both disclosure and agreement are to be "in writing." The commentary explains that architects may sometimes find it hard to avoid receiving payment from two parties—for example, when ordering a large number of windows from a supplier later produces a rebate check. The architect cannot simply accept the rebate (even if it comes as a surprise) but must first inform the client (and other interested parties) of the payment and the reason for it. The architect cannot accept the payment unless at least the client (and any other interested party) approves. The commentary explains that the "bifurcated loyalty" that such a rebate threatens is "unacceptable unless all parties have understood it and accepted it." The commentary does not limit the "parties" to the client. This is because in many architectural projects several parties may be affected by the payment, such as the engineering firm typically present at any large project, the developer (who may be the immediate client but who is, in fact, a stand-in for the ultimate owner), the ultimate owner (who may be one or more individuals or a legal entity), and even the contractor or subcontractor who must work with the rebated supplies. The commentary can even be interpreted as including the window supplier's competitors among those who must be informed of the payment and the reason for it. They are certainly "interested parties." They are at a competitive disadvantage if they are not also making such rebates.

Behind Rule 2.1 is a conception of architects as having a relatively settled loyalty to the client that everyone dealing with the client relies on. An unusual payment (such as the rebate described above) unsettles the situation. There is no question here of the supplier buying the architect's loyalty with the rebate (as there would be if the payment were a bribe or kickback). The problem is that "money talks," and even architects cannot gauge how much they will listen the next time that they place an order of that sort. Their judgment that their professional judgment will not be affected is not relevant. That, too, is now under suspicion.

Disclosure of the payment makes it possible for all interested parties to redefine their relationship to the architect to take account of this unusual feature. The client may, for example, require the architect to hand over the entire rebate (as well as ask other suppliers whether they will meet the com-

petition). However, because the architect's fee is often a percentage of the total cost of the project, this solution may not be the best. It would create a "perverse incentive." The architect would, in effect, be punished for saving the client money. The architect would have an incentive to avoid suppliers who give rebates. The client might then prefer to split the rebate with the architect, or they might work out some more complicated arrangement—of which all interested parties should be made aware to ensure that their trust in the architect's judgment is not misplaced.

Rule 2.2 concerns financial interests apart from payments, for example, stock in a potential supplier or a loan to a contractor. The architect must assess whether the interest (direct or indirect) is "substantial enough to influence his or her judgment in the performance of professional services" (whether or not it does or would in fact influence it). Architects thus have some discretion under this rule (as they do not under Rule 2.1). The rationale for allowing some discretion (concerning whether an interest is substantial enough) is that avoiding all financial interests seems too much to ask. For example, an architect with money in a large investment fund that holds a few shares of stock in one of the companies she or he is dealing with has an interest in that company. Is revealing such an interest worth the trouble? Should architects be required to avoid investing in any fund that might (on a given day) invest in a potential supplier? That seems too much to require, so long as the architect reveals any interest substantial enough to affect her or his judgment. Of course, when in doubt, the architect should reveal the interest. Rule 2.2 seems to work because it governs only interests other than payments, because architects seldom invest in suppliers and because most architects work in a small world (mostly developers or builders rather than individual clients) in which a substantial investment in a supplier would soon be known.

If the interest is enough to influence the judgment, the architect must fully disclose it in writing to the client or employer (thus creating a paper trail). If the client or employer objects to the business association or the financial interest, the architect must either terminate it or offer to give up the commission or employment. The client or employer may have good reason to accept the bifurcated loyalty that the business association or financial interest in question creates, but the decision is the client's or the employer's (or both, when an architect has both a client, the person who has hired the firm, and an employer, the architectural firm). That decision should be made only with all the relevant facts laid before the decision maker in a form that the decision maker can understand. If the architect is unwilling to make full disclosure, she or he must resign from the job. There is no middle way (no way to manage the conflict) without full disclosure and consent.

Rules 2.3 applies to any payment made in return for specifying or endorsing a supplier. Strictly speaking, this rule does not concern conflict of

interest but concerns bribes, kickbacks, and other side payments that buy the architect's judgment. Architects are simply forbidden to solicit or accept such payments. The brief commentary notes that this rule is "absolute"; that is, it admits of no exception, even when all the relevant parties would agree to the payment after full disclosure. So, for example, an architect cannot have an agreement with a supplier that she or he will recommend a certain window frame even if she or he fully informs the clients of that agreement and the clients say, "Fine." Why? Although many of the payments in question are in fact illegal, the rule is indifferent to their legality. Even legal payments for specifying or endorsing a supplier (say, lending one's name to an advertising campaign) are forbidden. What explains this striking departure from architecture's standard strategy of allowing conflict of interest when the relevant parties consent after full disclosure?

The answer seems to be this: conflict of interest threatens professional judgment. It makes it less reliable than it would otherwise be. Sometimes such threats cannot be avoided or cannot be avoided at reasonable cost. Those relying on the architect's judgment then have the right to weigh the costs and benefits and decide whether to take the risk. In contrast, an agreement to specify or endorse a product does not threaten professional judgment. It does something much more dramatic. The architect has, in this respect, signed away judgment. By the agreement, the architect gives up future judgment of the appropriateness of the product in question. The agreement with the supplier prejudges the matter. The architect cannot both claim the power of an architect in that respect (the right to use her or his judgment to decide what is appropriate in that case) and follow an agreement prejudging the case.

Side payments for endorsement are also, in one respect, unnecessary. The client or employer derives no benefit whatsoever from them, and (generally) the architect does not need them to survive or prosper. They are simply not an essential part of practicing architecture.

This explanation of Rule 2.3 treats it as something other than a rule concerned with conflict of interest. Selling one's judgment does not, in general, create a conflict of interest (that is, it does not threaten professional judgment). However, sometimes it does. For example, if Person A is paid to endorse a product as part of an advertising campaign, Person A will have a greater tendency to specify that product than he or she otherwise would. That tendency is what makes Rule 2.3 in part a rule concerned with conflict of interest. Forbidding endorsements for pay eliminates one sort of conflict of interest.

Rule 2.4 concerns the architect acting as adjudicator, that is, as the interpreter of building contract documents or the judge of contract performance. When acting in this role, an architect is to "render decisions impartially, favoring neither party in the dispute." The commentary makes clear that it is customary in the construction industry for the architect, even

though he or she is paid by the owner and owes loyalty to the owner, to settle disputes between the owner and a contractor, subcontractor, or supplier concerning whether work has been performed as the contract requires or whether the contract requires this or that. When acting in this capacity, the architect must (according to NCARB) act impartially. If the architect does not believe himself or herself to be capable of acting in that way, he or she "may appropriately decline to act in those two roles" (as the agent of the owner and as a judge between the owner and an adversary). The architect's role in such circumstances has a threat to independent judgment built into it (an interest but not a "special" interest). Both architects and those they work with are aware of that threat to independent judgment. They have traditionally tolerated it since the alternative is whatever delay is necessarily consequent on seeking a truly impartial judge far from the work site. Nonetheless, the architect must at least believe himself or herself to be able to render impartial judgment. If the threat to impartiality is significant enough that the architect doubts his or her own judgment, the architect may (and, indeed, should) decline. Interestingly, the rule is not satisfied if the architect merely believes himself or herself to be impartial; the architect must actually render an impartial decision. If the decision is obviously biased, the architect would be subject to discipline under the rule, even though the architect believed himself or herself to be impartial.

Like Rule 2.3, Rule 2.4 is an absolute rule (although the commentary does not say that explicitly). The rationale for its absoluteness is also much the same as that for Rule 2.3. The point of asking the architect to judge between the owner and those working on a site is to receive quickly (something approaching) impartial judgment (a judgment informed by the architect's knowledge of construction, the documents, and local custom). If the architect were known to be partial, his or her value as a judge would be much reduced. The rule preserves the usefulness of architects in settling such disputes (an efficiency serving everyone's interests in the long run). Like Rule 2.3, Rule 2.4 is (primarily) concerned not with conflict of interest, strictly speaking, but with something closely related, that is, the typical outcome of judgment free of conflict of interest (as well as of bias and prejudice): an impartial decision.

The last of NCARB's conflict of interest rules is Rule 3.1. It requires an architect making a "public statement on architectural questions" (that is, speaking publicly in a professional capacity) to "disclose when he or she is being compensated for making such statement or when he or she has an economic interest in the issue." So, for example, an architect paid by a developer to testify on behalf of a project would have to state that she or he is being so paid. An architect writing a journal article on behalf of a certain manufacturer's product would have to disclose ownership of even a single share of stock in that company. For public statements, the standard

of disclosure is more demanding than for statements to client, employer, or other private person. (The term "substantial enough" in Rule 2.2 has no counterpart in Rule 3.1.) The commentary explains why the standard is so demanding: to preserve "the probity which the public expects of the architectural profession," architects are "not allowed under the circumstances described in the rule to disguise the fact that they are not speaking on the particular issue as an independent professional but as a professional engaged to act on behalf of a client" or with a judgment perhaps arising from the wrong sort of interest (a private interest rather than the public interest). The public is entitled to know that the architect might have a certain bias (or even that, from the public's perspective, might seem to have a certain bias), a legitimate bias if it is disclosed but otherwise an illegitimate bias. If architects routinely made public statements in the service of clients without acknowledging that service or in the service of a private interest (however small) without acknowledging that service, their public statements would eventually lose the power that comes from their being thought to be independent. The public statements would be regarded as unreliable (as, indeed, they would be).

This rationale is as interesting for what it leaves out as for what it includes. Like most professions, architecture recognizes itself as having an obligation to serve the public interest (an obligation that may not belong in hard-edged rules but appears, for example, in Canon II of the AIA code). The NCARB commentary might therefore have appealed to this obligation in support of a rule governing public statements (protecting the public). Instead, the commentary appeals to the interest that the profession itself has in maintaining its reliability ("the probity the public expects") both to explain and support the rule.

AIA on Conflict of Interest

The NCARB rules just discussed are the hard-edged rules concerning conflict of interest that state registration boards use to decide whether to discipline a licensed architect. We turn now to the AIA's code. Like AMA, the AIA is a voluntary organization. Also like AMA, it no longer is an organization to which a majority of the profession belongs. Yet, just as no AMA member wants AMA to discipline her or him, so no AIA member wants the AIA to discipline her or him. An AIA member charged with wrongdoing will generally hire a lawyer to present her or his side at the National Ethics Council (NEC) and, if the AIA member loses there, may seek redress in the courts. At least as much as physicians, architects live by their reputations. For that reason, an NEC-appointed hearing officer collects evidence and the full NEC (minus the hearing officer) decides the case in secret. However, for any serious discipline (censure, suspension, or expulsion), the ultimate deci-

sion is made public (the architect's name disappears from the membership role, and the architect can no longer be listed as an AIA member). The NEC publishes its decision in the form of a judicial opinion, stating the facts found, the penalty, and the rationale for it, without identifying the parties. The NEC also issues interpretations of the code (Advisory Opinions).[58]

The AIA code (2007) is about half the length of NCARB's and devotes proportionally much less space to conflict of interest. Canon III (Obligations to the Client) provides the overall framework for conflict of interest. AIA members should "exercise unprejudiced and unbiased judgment when performing all professional services." Ethical Standard 3.2 (titled Conflict of Interest) simply states the general strategy for avoiding tendencies to bias and prejudice. Members should "avoid conflicts of interest in their professional practices and fully disclose all unavoidable conflicts as they arise." There are only two disciplinary rules under this ethical standard. The second rule, Rule 3.202 (render decisions impartially), merely restates NCARB's Rule 2.2 (with a briefer commentary), but the first rule, Rule 3.201, adds something new.

Rule 3.201 prohibits AIA members from rendering professional services if their "professional judgment could be affected by responsibilities to another project or person, or by [their own] interests." The only exception to this prohibition is (the usual) "unless all those who rely on the Member's judgment consent after full disclosure." Rule 3.201 understands "interest" as including more than financial interest. Any "responsibility" to another project or person that could affect a member's judgment is an interest for the purposes of this rule (as is any self-interest, even if it is not financial or familial). The commentary underscores the point. The rule is, it says, "intended to embrace the full range of situations that may present a Member with a conflict between his interests or responsibilities and the interests of others." The commentary goes on to give an equally wide reading of "all those who rely." Those entitled to disclosure "may include a client, owner, employee, contractor, or others who rely on or are affected by the Member's professional judgment." An AIA member who cannot appropriately disclose a "conflict directly to the affected person must take steps to ensure that disclosure is made by another means." (Direct disclosure may not be possible because the client is, for example, an individual who is out of town or an organization whose officers are hard to reach; sending notice is not equivalent to "appropriate disclosure.") If a member cannot make adequate disclosure of a conflict of interest (directly or indirectly), he or she cannot render the professional services in question. The member must decline or withdraw.

In addition to the rules under Rule 3.2, there are at least two rules in

[58] For either, see www.aia.org/about_ethics#nec.

Canon II (Obligations to the Public) that are (at least in part) concerned with conflict of interest. Rule 2.103 forbids an AIA member from serving in a public capacity to "accept payments or gifts which are intended to influence their judgment." This rule covers bribes (payments made in exchange for some future illegal service) but not kickbacks (a payment for a referral or some other favor already done). The rules cover more than bribes, for example, a dinner or a gift of theater tickets of whatever value given with the intention of influencing judgment. This additional coverage is what justifies discussion of this rule as concerned with conflict of interest.

This is another absolute rule. It is nonetheless unusual in one respect. It is the intention of the payer or giver, not its likely consequence or the recipient's intention, that determines whether the payment or gift is prohibited. The rationale for this approach to payments and gifts is obvious. An architect serving in a public capacity will, in the ordinary course of life, receive many payments and gifts. Prohibiting them all would be unreasonable, but some should be prohibited. For example, no one wants to forbid a gift from the architect's mother or brother-in-law that is part of the normal exchange of gifts among family members. (Such gifts would seldom be given with the intent of influencing the architect's professional judgment.) In contrast, the AIA would, presumably, want to prohibit a gift from a potential developer hoping to reduce the hostility of an architect toward a project that he or she has in mind when that architect is a member of the local planning commission.

Rule 2.301 is concerned with public statements on architectural issues. It is (almost) identical to NCARB's Rule 3.1. Although there is no commentary, its placement under the canon concerned with obligations to the public suggests that its rationale is a bit different. Architects perform a useful service whenever they inform the public of their judgments on architectural issues. They perform a useful service whether they speak disinterestedly or on behalf of a client or interest. However, the service performed is different. Rule 2.301 requires architects to make clear which service they are performing so that their audience, the public, can evaluate it using the appropriate criteria. The underlying rationale is not so much to protect independent judgment as it is not to mislead the public concerning what it may reasonably expect of the judgments offered. The public's trust in what architects say depends in part on knowing who they are working for when they say it.

ENGINEERING

Engineering and medicine have historically been very different professions. Engineers have, for example, generally worked in large organizations, beginning with the army; physicians (like architects) have, until recently,

generally worked alone or in small practices (with or without an affiliation with a nearby hospital). Those who employ engineers tend to be the rich and the powerful, not the sick or the wounded. When a work of engineering fails, the result may be hundreds or even thousands of deaths—typically of people of whom the engineers knows little—not, as in conventional medicine, just one person, a patient, known to the physician. (Of course, when physicians advise the Food and Drug Administration [FDA] or a drug manufacturer, the analogy with engineering is much closer.) For these reasons (and others), many of the conflicts of interest that engineers have thought about over the last century lack an exact analogue in medicine. They are nonetheless worth considering in detail because they illustrate how a profession can work from a basic understanding of conflict of interest to a system of detailed rules likely to be of use to practitioners in what would otherwise be situations hard to navigate. To understand the system of rules, it is important to understand something of the institutions in which they are embedded.

Background Institutions

Engineering is divided into four major disciplines (as well as many smaller ones): civil, mechanical, electrical, and chemical. These are more closely related to each other than medicine is to such other health care disciplines, such as dentistry or osteopathy. That is, they are generally taught in departments of the same school; the curricula are similar, especially in the first 2 undergraduate years; the schools have the same accreditation body (ABET, Inc.);[59] and students receive the same first degree upon graduation, a B.S. (with different majors). Nonetheless, engineering has never created the equivalent of AMA. Instead, there are five major societies. One each for the major disciplines: the American Society of Civil Engineers (ASCE), the American Society of Mechanical Engineers (ASME), the Institute of Electrical and Electronic Engineers (IEEE), and the American Institute of Chemical Engineers (AIChE). The fifth major society, the National Society of Professional Engineers (NSPE), cuts across these four. Its members are (primarily) Professional Engineers (PEs). A PE is an engineer (of any discipline) licensed by a state (in much the way that lawyers, CPAs, architects, and physicians are), but only about a fifth of all U.S. engineers are so licensed. The rest, who work in large organizations, do not need a license to practice because of what is known as "the industrial exemption." Although they are not PEs, they

[59] ABET was formerly the American Board for Engineering and Technology; the name change to ABET, Inc., reflects its expansion into new areas.

are full members of the engineering profession.[60] The five major societies (along with many of the smaller ones) frequently cooperate ad hoc as well as maintain many permanent bodies, of which ABET is among the oldest and the most important.

This complexity reappears in the codes of ethics governing engineers. Except for a brief period a half century ago, each of the five major societies has had its own code (as have many of the smaller societies); and, as if this were not enough ethical complexity for one profession, ABET (or its predecessor) has had a separate code (which has not been amended since 1977),[61] one that most engineering societies have endorsed.

Although the relationship among these codes is complex, it is not muddled. The NSPE code[62] is designed (like architecture's NCARB code) primarily for adoption by state licensing boards. Its rules are supposed to be appropriate for use in a disciplinary hearing. In contrast, the ABET code is designed to guide individual engineers. ABET has no enforcement procedure whatsoever (and does not even have a committee to issue advisory opinions) and, apparently, no interest in having its code enforced through any formal procedure. The ABET code thus functions much as the AIA's Ethical Standards do and should therefore be more demanding that the NSPE code. In fact, today it is as often less demanding than more demanding.

Until the 1980s, ABET's code was clearly the most important in engineering. Most engineering societies, including two of the major ones (ASME and ASCE), had adopted it as their own (either the 1977 version or one of its predecessors). In the last decade, however, its importance has declined dramatically. Some societies have amended their codes now and then, to the point that there are now important differences between those codes and ABET's code. Some of the differences arise from the adoption of provisions that the NSPE adopted; some arise from local innovations (which other societies may or may not have followed). In addition, some societies (most notably, the IEEE) have abandoned the ABET code altogether.

The NSPE code now seems destined to become the de facto standard of the profession (in part because the ABET code has gone so long without

[60] Because most engineers are unlicensed, most continuing education depends on employers or on individual engineers. Large employers generally have their own internal technical courses (which the employer funds). Some continuing education goes on in universities as degree programs, certificate programs, or specific technical courses. Most large employers pay for an engineer's continued technical education. Engineers may also be trained by a supplier, once the employer has contracted for some new product (such as software). Most states require PEs to take accredited continuing education courses. Accreditation of such courses is handled much as it is in accounting, architecture, and law.

[61] See http://ethics.iit.edu/codes/coe/accreditation.board.engineering.tech.a.html (Code); http://ethics.iit.edu/codes/coe/accreditation.board.engineering.tech.b.html (Guidelines).

[62] See www.nspe.org/ethics/.

amendment and the IEEE code lacks sufficient detail to provide much guidance). The NSPE code is now much more often reprinted at the back of a text in engineering ethics than any other code. Although it is distinct from ABET's code, NSPE's code resembles it in layout and language because both derive from the "unity code" of a half century ago. Only the IEEE has an independent code (2000)[63]—which some other engineering societies, including the AIChE (2002), have followed. The IEEE code is quite short (260 words) and applies to IEEE members (not to engineers), an important distinction because many IEEE members are not engineers but are computer scientists, physicists, mathematicians, or the like.

This survey confines its review of engineering's methods of dealing with conflict of interest to three codes, those of the IEEE, the NSPE, and ABET, the most important (and distinctive) in U.S. engineering. For all the small differences among these three codes, there is a fundamental agreement about how to deal with conflict of interest.

IEEE Code

The one sentence on conflict of interest in the IEEE code expresses that fundamental agreement succinctly. IEEE members are to "avoid real or perceived conflicts of interest whenever possible, and to disclose them to affected parties when they do exist." The IEEE strategy for dealing with conflict of interest (avoidance whenever possible and disclosure whenever avoidance is not possible or has failed) is similar to that identified for architects but nonetheless differs in two important respects. First, the requirement of avoidance applies not only to "real" conflicts of interest but also to "perceived" ones. Perception—that is, the appearance—of a conflict of interest is treated as being just as bad as the reality. The underlying idea seems to be that an engineer's professional judgment (or, rather, an IEEE member's professional judgment) should be above suspicion. Even perceived conflicts should therefore be avoided (whatever the underlying reality about the interests in question). The underlying reality does not matter to those who would like to rely on an engineer—until it is disclosed and the false appearance is dispelled.

The second important respect in which the IEEE strategy differs from that identified for architects is that there is no indication of what is to be done after disclosure (for example, there is no requirement of consent before continuing). The other engineering codes do provide guidance concerning this question, although the particulars vary a good deal, depending on the circumstances in question. The IEEE has a committee to prepare guidelines to supplement its code.

[63] See www.ieee.org/portal/pages/iportals/aboutus/ethics/code.html.

NSPE Code

The NSPE code is divided into three main parts: a brief, four-sentence preamble; the body of the code, which consists of Part I. Fundamental Canons, Part II. Rules of Practice, and Part III. Professional Obligations; and an addendum (which may be ignored here) that quotes a 1978 federal court decision on competitive bidding and the response of the NSPE Executive Committee. The fundamental canons (about 3 percent of the code) contains three sentences relevant to conflict of interest (in language dating from one of the first engineering codes): "Engineers, in the fulfillment of their professional duties, shall: . . . 3) Issue public statements only in an objective and truthful manner. 4) Act for each employer or client as faithful agents or trustees. 5) Avoid deceptive acts."

The Rules of Practice (which accounts for a quarter of the code's 2,400 words) has six main rules, each of which corresponds to one of the Fundamental Canons. The specific rules under a rule (designated with lowercase letters) are applications or elaborations of the prefacing rule. There are 3 rules under Rule II.3, 5 under Rule II.4, and 2 under Rule II.5, for 10 rules in all. All but two of these (Rules II.3a and II.3b) concern conflict of interest (more or less). In addition, Professional Obligations (about 40 percent of the code) contains six more rules related to conflict of interest. In all, about a fifth of the entire code is concerned with conflict of interest. Apparently, the NSPE takes conflict of interest very seriously. A detailed review of the provisions shows that they cover a surprisingly large number of specific issues.

Rules of Practice

Rule II.3c forbids engineers from issuing "statements, criticisms, or arguments on technical matters that are inspired or paid for by interested parties, unless they [the engineers] have prefaced their comments by explicitly identifying the interested parties on whose behalf they are speaking, and by revealing the existence of any interest the engineers may have in the matters." Although Rule II.3c is similar to NCARB's Rule 3.1 (and AIA Rule 2.301), Rule II.3c differs in one striking respect. The engineer must not only reveal payment for a statement, criticism, or argument but even inspiration, presumably something more than NCARB's "financial interest." Although a financial interest might "inspire" a statement, so might friendship, the urging of a relative, or some other connection unrelated to compensation or financial interest. Although the language is vague, it is obviously meant to sweep wide (something that we might not expect in a code designed for discipline rather than for personal guidance). Why is there such a demanding rule?

For an engineer, the rationale for Rule II.3c is pretty straightforward. Because the rule is under Section 3, it concerns public statements. Engineers view the public much as physicians view patients. Engineers are—as Fundamental Canon 1 puts it—to "[h]old paramount the safety, health, and welfare of the public." There is no official definition of "public"; there is even some debate about the exact boundaries of the public, for example, whether the public includes employees of one's client or employer. The most popular view, though, seems to be that the public includes all those who, owing to a lack of knowledge, power, or opportunity, are unable to protect themselves fully from what engineers do. What engineers call "the public" is (more or less) as dependent on engineering judgment as the physician's patient is dependent on the physician's judgment.

Insofar as what engineers say in public may be influenced by an interested party other than the public, the public needs to know about that influence if it is to decide the appropriate weight to give the statement. The engineer, of course, tries to speak "in an objective and truthful manner" (as Canon 3 requires). If the engineer is not trying to do that, he or she should not speak at all (or, at least, not claim to speak as an engineer). However, if an engineer is aware of an influence that might (but also might not) undermine his or her ability to speak in an objective and truthful manner, he or she must warn the public of that danger to objectivity. There is nothing wrong with issuing public statements in the service of a client or an employer (as long as the statements are objective and truthful). There is, however, something wrong with an engineer giving the impression that he or she is doing something else, that is, expressing independent professional judgment (one independent of an employer, client, or other interested party) when it is not. An engineer must not give a false impression if he or she can reasonably avoid it. Experience and common sense suggest that an engineer may easily avoid giving that false impression by explicitly stating what he or she is doing as he or she begins the public statement in question.

All the rules under the next heading (Rule II.4) are concerned with protecting the client or the employer, not the public. The strategy for dealing with conflict of interest is much the same as that expressed in Rule II.3c. Rule II.4a explicitly uses the term "conflict of interest." Engineers are supposed to "disclose all known or potential conflicts of interest that could influence or appear to influence their judgment or the quality of their services." There is no requirement to avoid those that can be avoided. The rule seems to be concerned with those conflicts that cannot be (or that perhaps just have not been) avoided. Rule II.4a makes something like the distinction between the IEEE's "real" and "perceived" conflicts of interest, that is, between conflicts of interest that "could" influence and those that merely "could appear" to influence a judgment (or the quality of service). There is, however, a new distinction, that between "known" conflicts of in-

terest and those that are merely "potential." Although the distinction seems confused (should not the contrast be between "actual" and "potential" or between "known" and "unknown"?), the intent of the language seems to be clear enough: again (as in Rule II.3c), to sweep as widely as possible. Rule II.4a bars such excuses as, "I didn't know it was a conflict of interest" and "It was only a potential conflict of interest." Lastly, there is no attempt to distinguish financial interests from other kinds of interests. The rule applies to any conflict of interest whatsoever.

Rules II.4b and II.4c are similar to NCARB's Rules 2.1 and 2.2. They make avoidance the standard response to a conflict of interest. Rule II.4b forbids engineers from accepting "compensation, financial or otherwise, from more than one party for services on the same project, or for services pertaining to the same project, unless the circumstances are fully disclosed and agreed to by all interested parties." Rule II.4c forbids engineers from soliciting or accepting "financial or other valuable consideration, directly or indirectly, from outside agents in connection with the work for which they are responsible." The only significant difference between these two rules and the corresponding NCARB rules is (again) a wider sweep. Rule II.4b concerns compensation "financial or otherwise"; Rule II.4c concerns "other valuable consideration" as well as just "financial" ("directly or indirectly" solicited or accepted). So, a dinner, help finding another job, an all-expenses-paid trip to Jamaica, and a free course in some engineering subject, although they are not strictly financial compensation for work on a project (or "pertaining to the same project"), would clearly be close enough to require disclosure under Rule II.4b if they were, for example, offered in the way of offering thanks for favors done on a project. Similarly, although such things might not count as financial considerations, they still seem to count as consideration enough to be forbidden under Rule II.4c (coming from "outside agents").

The last two rules under Rule II.4 concern possible clashes between the engineer's obligations to the public and obligations to a client or an employer. Rule II.4d forbids engineers in public service as members, advisors, or employees of a governmental or a quasigovernmental body or department to "participate in decisions with respect to services solicited or provided by them or their organizations in private or public engineering practice." Engineers in public service are to recuse themselves whenever they, their employer, or their client has an interest in a decision. The client or employer may be a private firm, but the engineer should recuse himself or herself even if the client or the employer with an interest in the decision is another governmental (or quasigovernmental) agency. The rule makes no exception in the case of "full disclosure." The idea seems to be that engineers serving in government (in whatever capacity) or in a quasigovernmental agency (such as AMTRAK or the U.S. Postal Service) are supposed

to put their independent judgment at the public's service. Disclosure of a conflict of interest to the relevant agency does not, as such, protect the public. Even the agency's informed consent does nothing to ensure protection of the public interest. The disclosure would have to be made to the public directly in a way that allows the public to take appropriate action. This can seldom happen when the engineer is advising a public agency (as it can when an engineer is speaking to the public directly). Disclosure to the relevant agency does not necessarily reach the public, and even when it does, the agency and not the public would ordinarily make the decision. So, the only way to protect the public from an engineer's conflict of interest when the engineer's judgment, though exercised in behalf of the public, works through a public agency, is to have the engineer avoid participation in the decision.

Rule II.4e adopts the same strategy with respect to soliciting or accepting "a contract from a governmental body on which a principal or officer of their organization serves as a member." (For some reason, this rule is silent concerning quasigovernmental bodies.) Again, neither mere disclosure of the conflict nor disclosure with consent is enough. The engineer must never solicit or accept such a contract. Although Rule II.4e concerns conflict of interest, it is not designed to protect the engineer's judgment (as the others are) but is designed to protect the judgment of the principal or the officer of the organization that the engineer serves. Indeed, it seems to be designed to protect the principal or the officer in question from the appearance of conflict as well as from actual conflict. There is no requirement that the principal or officer know of the contract or have anything to do with obtaining it. Protecting the principal or officer in question from the appearance of conflict of interest is part of being a faithful agent or trustee.

Rule II.5b consists of three long sentences mostly concerned with bribery, but a part of the first sentence seems designed to avoid both certain conflicts of interest and the mere appearance of them (as well as actual bribes): "Engineers shall not . . . receive, either directly or indirectly, any contribution to influence the award of a contract by public authority, or which may be reasonably construed by the public as having the effect or intent of influencing the awarding of a contract." The expression "reasonably construed" is, of course, a somewhat lower standard than "perceived," as used in Rule II.4a. "Perceived" may be interpreted to include unreasonable as well as reasonable construal. The reason for the change in terms is not obvious (or known). One explanation is that what the public might reasonably construe as taking a bribe or as being a threat to judgment is too close to dishonesty (the concern of Rule II.5) to be good for engineering's reputation. However, what might unreasonably be so construed is not. There are other ways to deal with unreasonable construal; for example, pointing

out how unreasonable it is. In this context, an engineer should be above "reasonable suspicion" but cannot avoid all suspicion.

One problem with the use of "the appearance [or perception] of conflict of interest" is its subjectivity. What appears to be is in part a matter of the psychology of the person doing the perceiving. The mad, the overly suspicious, or the profoundly cynical might see a conflict of interest where no one else would. In contrast, what might reasonably be construed as a conflict of interest, given the evidence available to the person doing the construing, is an objective matter. Even if we know that there is no conflict of interest (for example, because we know that the investments in question are in a blind trust), we can see that the public would be right to draw the opposite conclusion if all it knew was, say, that the engineer in question held the compromising investment. The public's construal of the situation is, on the basis of the evidence, reasonable.

Although the distinction between reasonable construal and unreasonable construal is important, it may not be as important to interpreting the NSPE code as it seems. All codes of ethics must be applied by using reasonable interpretive principles. One principle of reasonable interpretation is that, unless it is unavoidable, an interpretation should not lead to logical impossibility or practical absurdity. Because the avoidance of all perception or appearance of conflict of interest is probably impossible or at least unreasonable, it seems likely that even the code provisions that do not specify the "reasonableness" of the perception or appearance in fact assume it—or, at least, should be interpreted as so doing.

Professional Obligations

So far we have been examining the part of the NSPE Code of Ethics called Part II. Rules of Practice. That part explicitly provides interpretations of Fundamental Canons 1 to 5, rules designed to protect the public, client, and employer. We now turn to the next part, Part III. Professional Obligations, rules that seem to offer interpretations of the remaining Fundamental Canon, which requires engineers to "Conduct themselves honorably, responsibly, ethically, and lawfully so as to enhance the honor, reputation, and usefulness of the profession." This section has nine main rules, numbered like the Rules of Practice, but not obviously derived from the wording of either the preamble or the Fundamental Canons. Except for not overlapping much with the Rules of Practice, there is no obvious unity in the subject matter of Part III. It is, in effect, a code within a code concerned (primarily) with enhancing the honor, reputation, and usefulness of the profession rather than with protecting the public, the client, or the employer (though following its rules would often have that effect too). Part III has three rules concerning conflict of interest: Rules III.4, III.5, and III.6.

Rule III.4 protects the confidentiality of business and technical information that engineers learn while they are acting in a professional capacity. Rule III.4a is concerned with the unreliability in judgment that arises from trying to judge as one would if one did not know what one in fact knows. That rule forbids engineers "without the consent of all interested parties, [to] promote or arrange for new employment or practice in connection with a specific project for which the engineer has gained particular and specialized knowledge." The engineer must have the consent of "all interested parties," generally, the old employer and the new one (as well as clients, if any), because she or he would be in an ethically untenable position otherwise. The engineer has an obligation to maintain the confidentiality of all specific business and technical information learned at the present employer (apart from what has become the engineer's skill, experience, or general knowledge). At the new job, the engineer will have an obligation to act as a faithful agent, using her or his best engineering judgment on behalf of the new employer (or client), just as she or he did at the old employer. The engineer cannot use her or his best engineering judgment while trying to ignore some of what she or he knows (say, the specifics of a new product under development). If the engineer "bends over backward" to be fair to the previous employer, she or he will not treat her or his new employer as she or he should. The engineer will give the new employer less than her or his best. If, however, the engineer does not bend over backward to be fair, she or he cannot know that she or he has treated the old employer as she or he should. (To avoid revealing too much, the engineer needs a margin of safety, which means revealing too little.) Without guidance from the fully informed "interested parties," the engineer is likely to fail the past employer, the new employer, or both. Because much technical and business information consists of trade secrets, the engineer may even provoke a lawsuit between the past and the present employer.

The only way to avoid all of these troubles, apart from never changing jobs or never seeking new employment closely related to projects that one has worked on before, is to have the parties work out an arrangement in advance of the move from one company to another. The arrangement may be as simple as the new employer agreeing to buy a right to use the technology in question or as complicated as an agreement stating what kinds of projects the engineer can work on for a specified period (say, 2 years).

Why does Rule III.4a not simply forbid engineers to seek employment too closely related to previous work? Why does it allow the consent of interested parties to resolve the conflict of interest problem (even if it does not resolve the underlying threat to judgment)? The (primary) moral wrong that conflict of interest threatens is a betrayal of justified reliance (rather than actual biased judgment). Engineers undertake to provide a certain level of service, that is, to be a reliable source of independent professional judg-

ment concerning engineering. Conflict of interest means that an engineer can no longer safely be relied on for such judgment within a certain range of activities. If an interested party, that is, someone justified in relying on that judgment, is alerted to the problem by its disclosure and, by its (informed) consent, accepts the risk, the possibility of betrayal (in that respect) is eliminated. The profession's honor and reputation for honor are preserved. What remains is only a practical problem of protecting the various interests at stake from biased judgment (that is, protecting engineering's usefulness and its reputation for usefulness). One of those interests is the public's interest in the productive use of what the engineer knows. Forbidding engineers to move from one job to a closely related one would waste some of what the engineer has learned (a social resource as well as a personal one) and make it harder for employers to find the engineers that they need.

The rationale for Rule III.4b is similar. The rule forbids engineers, "without the consent of all interested parties, [to] participate in or represent an adversary interest in connection with a specific project or proceeding in which the engineer has gained particular specialized knowledge on behalf of a former client or employer." Engineers frequently testify in court, arbitration hearings, and similar proceedings on behalf of one side or the other. The United States does not have a system of official experts for tribunals to rely on. Representation or even participating in an adversary representation (for example, by testifying as an expert witness for one side or the other) may seem like a betrayal of trust or reliance (whether or not it is), if the engineer's expertise derives even in part from specialized knowledge gained in the course of working for the adverse party ("biting the hand that once fed him or her," so to speak). The engineer should appear as an expert in such a proceeding (or otherwise participate in it) only if all the interested parties welcome the engineer as an independent expert or at least as someone who is not going to betray their justified trust or reliance. Again, the honor and the reputation of engineering are preserved. (The number of engineers makes it unlikely that the adverse party will fail to find a qualified witness even if one party rejects the first engineer for conflict of interest.)

Rule III.5 forbids engineers to "be influenced in their professional duties by conflicting interests." The rule should not be interpreted as forbidding engineers to be influenced by conflicts of interest because, so interpreted, it would be inconsistent with all of the rules discussed so far, which permit conflicts of interest when there are full disclosure and consent (however, the interests, in fact, influence the decision). The only way to avoid being influenced by a conflict of interest is to avoid the conflict of interest or, having failed to avoid it, to recuse oneself. There is no other way to ensure that the decision in question is not influenced. (Disclosure and consent protect against betrayal of trust, not the loss of independent judgment itself.) So, Rule III.5 must instead be understood as forbidding

certain kinds of interests, those that always (or at least too often) conflict with an engineer's professional duties.

The two rules under Rule III.5 confirm this inference. Rule III.5a bars the acceptance of "financial or other considerations, including free engineering designs, from material or equipment suppliers for specifying their product." (Free engineering designs, sometimes including free software, are the engineering equivalent both of the free samples of drugs that physicians receive and of drug company-sponsored courses.) Rule III.5b also bars the acceptance of "commissions or allowances, directly or indirectly, from contractors or other parties dealing with clients or employers of the engineer in connection with work for which the engineer is responsible." There is no exception for disclosure and consent. The engineer can easily avoid such interests without failing to do anything that an engineer should do for the public, a client, or an employer. The engineer should not put his or her interests in financial gain ahead of the interests of the public, a client, or an employer in having the engineer's independent judgment.

Finally, Rule III.6 is concerned with obtaining employment. Although most of the rules under it have nothing to do with conflict of interest, one does. Rule III.6a forbids engineers to "request, propose, or accept a commission on a contingent basis under circumstances in which their judgment may be compromised." At one time, most engineering codes simply forbade engineers from working on a "contingent basis" (that is, where payment, all or just part, depends on success). One consequence of a series of antitrust cases brought against professions in the 1970s was that the rule against contingent fees was declared an unreasonable restraint of trade. The NSPE then sought to restate the rule to make clear its intent, which was not to raise the fees that engineers could charge for failure but to protect engineering judgment. Engineers might, it was thought, take chances that they should not take if their income depended even in part on "success"—success not in the sense in which engineers understand it (which takes into account the public's long-term interests) but in the sense in which a client or employer might understand it (for example, getting a product out the door by a certain date). Hence, Rule III.6a is another absolute rule. The consent neither of the client nor of the employer would permit an engineer to enter a fee contingent arrangement that might compromise her or his judgment.

That completes the survey of how the NSPE code of ethics regulates conflict of interest. That does not, however, complete the survey of NSPE's regulation of conflict of interest. In addition to the code, the NSPE maintains the Board of Ethical Review (BER), which receives inquiries from NSPE members concerning questions of ethics and issues opinions in response.[64] BER publishes between 6 and 13 opinions each year. About

[64] Many of these, including most since 1990, are available at www.niee.org/cases/.

a quarter of these are indexed under "conflict of interest" (among other categories). Space does not allow for an examination of these, but such an examination would only confirm the guiding principles sketched so far: avoid all conflicts of interest that can reasonably be avoided, whether they are actual, potential, or merely apparent. Tolerate the remainder only if full disclosure to interested parties and their informed consent give them the tools that they need to protect against less reliable judgment. Neither consent nor disclosure is enough when an affected party cannot protect itself once it is fully informed.

ABET Code

The ABET code consists of two major parts: the Code of Ethics proper, which is a short document (210 words), and the much longer Suggested Guidelines for Use with the Fundamental Canons of Ethics (2,667 words). The Code of Ethics is divided into Fundamental Principles (which have much the same content as the NSPE preamble) and Fundamental Canons (which have much the same content as NSPE's Fundamental Canons). The ABET guidelines correspond to the rest of the NSPE code (Parts II and III).

For the purposes of this paper, the only significant difference between the two codes (apart from the guidelines) is that ABET's Fundamental Canon 4 has been amended to append to the language of the NSPE code a comma and the words "and shall avoid conflicts of interest." Most engineering codes of ethics now include that amendment, the result of a scandal in the middle 1970s that ended in a $7.5 million judgment against ASME.[65] Some volunteers in one of ASME's standard-setting bodies, although faithful agents and trustees of their employer (as Fundamental Canon 4 then required), had a conflict of interest when acting as members of the committee. Because the engineers involved were members of ASME, as well as volunteers, ASME had not been their client or employer (in the ordinary sense of these terms). They had not (it seemed) violated Fundamental Canon 4 (or any other rule in effect at the time). Yet, most engineers thought that they had clearly done something that an engineer should not do. Since Fundamental Canon 4 did not seem to cover the case, although it should have, ABET revised Fundamental Canon 4 (adding the reference to conflict of interest), and most other engineering societies followed (with the notable exception of NSPE—which dealt with the problem by adding or amending rules *under* its equivalent of Fundamental Canon 4).

[65] See *ASME v. Hydrolevel Corp*., 456 U.S. 556 (1982).

ABET Guidelines

Although the ABET Guidelines were explicitly designed for use with the Fundamental Canons, they are an independent code in structure (and they were in fact the body of the code itself until 1977). The guidelines consist of seven main divisions, each of which is identical to one of the code's Fundamental Canons (and carries the same number). Under each of these are lettered sections and sometimes numbered subsections interpreting or applying the canon. Many of the sections are identical in language to provisions of the NSPE code. Some differ in ways not important here. For example, ABET Rule 3d differs from NSPE Rule III.3c in using "engineering matter" rather than "technical matter," by requiring engineers to identify themselves (as well as the party for whom they are speaking), and requiring them to describe any "pecuniary interest" that they may have in what they are about to say (rather than just any interest). In what follows, we ignore such small differences, focusing on rules that add something important to what we found in the NSPE code. There are only two such rules. They are, not surprisingly, both under Canon 4 (the canon explicitly concerned with avoiding conflict of interest).

Rule 4a of ABET's code differs from its NSPE counterpart (Rule II.4a) in requiring engineers to "avoid all known conflicts of interest" (rather than simply to disclose them) and to disclose promptly to their clients or employers the rest, what the NSPE code identified as "potential" conflicts of interest: "any business association, interests, or circumstances which *could* influence their judgment or the quality of their services" (emphasis added). This guideline makes explicit what we had found implicit in NSPE's Rule II.4a. The ABET rule may, nonetheless, be less demanding than its NSPE counterpart. If the adjective "business" applies to "interest" and "circumstance" as well as to "association" (a natural reading), then Rule 4a does not require disclosure of all conflicts of interest but only those arising from business associations, business interests, or business circumstances.

The theme of avoidance is carried through the rest of the conflict of interest provisions under Rules 4b to 4g—all of which, except for Rule 4b, are (more or less) identical to the rules in the NSPE code (and, in fact, date from some of the earliest codes of engineering ethics). The exception, Rule 4b, forbids engineers to "knowingly undertake any assignments which would knowingly create a potential conflict of interest between themselves and their clients or their employers." The two uses of "knowingly" suggests not only sloppy editing but also a great concern that engineers not be blamed for undertaking such assignments inadvertently. The requirement of knowledge is a break with the ABET code's general policy, which is to require avoidance or disclosure without providing for the excuse "I did not know." (In other words, engineering codes generally treat ethical conduct as a question of competence for which "I did not know" is an

admission of wrongdoing and not an excuse.) There is only one other use of "knowingly" in the entire code, one of which is unrelated to conflict of interest (Rule 6a, avoiding association with a disreputable business). Rule 4a's knowledge requirement (like the use of "conflict of interest") is new to the 1977 code. However, it is an innovation that some other codes have followed. For example, Rule 4b in ASME's current code (2002) is simply a cleaner version of ABET's: "Engineers shall not undertake any assignments which would knowingly create a potential conflict of interest between themselves and their clients or their employers."

Conclusions from Survey of Engineering Codes

For engineering, then, conflict of interest is a threat to the profession's usefulness (the reliability of its judgment) as well as to its honor and reputation. For most purposes, the best response to an actual or potential conflict of interest is to avoid it as soon as one learns of it. In a few cases, recusal is allowed (or required); in others, those cases in which (1) disclosure allows the public, client, and employer an adequate response and (2) the engineer cannot be replaced or cannot be replaced at reasonable cost, tolerance of a conflict of interest is allowable. However, it is only allowable. Even then, there is a risk to all who rely on the engineer's judgment that the engineer's judgment will not be as good as it should be (and would be but for the conflict of interest). Disclosure is not a cure-all.

COMPARATIVE OVERVIEW

This survey has discussed both similarities and differences in the treatment of conflicts of interest by four important professions. What can be learned from this survey of lawyers, certified public accountants, architects, and engineers? The obvious point is that all four professions take conflict of interest in professional practice very seriously. The recent history of public accountancy shows that failure to take conflicts of interest seriously enough can result in federal regulation. Engineering had a similar experience three decades ago with civil liability.[66]

With the exception of engineering, these professions do not undertake the kind of scientific research carried out by some in the medical

[66] *American Society of Mechanical Engineering, Inc. v. Hydrolevel Corp*., 456 U.S. 556 (1982), in which the U.S. Supreme Court held that ASME was strictly liable for the acts of its agent (the chairman of ASME's Boiler and Pressure Vessel Codes Committee) if those acts are in breach of antitrust laws (the chairman, an officer in the competitor of Hydrolevel, had a financial interest in his committee, finding that Hydrolevel's product did not meet ASME's code).

profession.[67] They have therefore not had to deal with controversies over conflicts of interest in research. Although each profession sets standards for providers of continuing professional education, they have, it seems, not faced any significant conflict of interest in education either.[68]

One reason for the relatively low level of attention given to conflicts of interest in research and education may be that lawyers and accountants do not act as gatekeepers for significant numbers of products and services as physicians do when they prescribe medications, use medical devices, order diagnostic tests, and the like. To the extent that architects and engineers are gatekeepers for supplies, their codes of ethics carefully regulate relationships with suppliers, gifts from suppliers, and other entanglements with suppliers that might threaten their professional judgment.

All four professions treat conflict of interest situations as risk situations; bias, breach of confidentiality, fraud, and malpractice are dealt with separately. Conflicts of interest are understood to threaten the quality of the individual professional's judgment and, as a consequence, the well-being of the client or employer in question, the profession's usefulness to the public (depending on the specific circumstance), and the reputation of the profession as a whole. The four professions express concern about conflict of interest in somewhat different ways and justify their management measures by appealing to different core values. The three most prominent values are loyalty to the client (or the employer), professional judgment, and public service. Beyond the fact that the four professions share these three most prominent values, we can draw at least 13 other conclusions:

1. Each profession has, over time, developed at least one detailed national code of professional ethics. Each of these codes is generally adopted (sometimes with amendments) by state-level professional organizations, licensing boards, or both. All these codes include general principles as well as more specific rules. A substantial part of each of these codes addresses conflicts of interest, describing what the profession understands conflict of interest to mean and how members of the profession should deal with

[67] Publishable engineering research generally goes on in (1) universities, (2) government laboratories, or (3) private laboratories (such as IBM's Watson Research Center). Most of this engineering research is scientific and is therefore subject to federal conflict of interest rules much as most medical research is. Relatively little engineering research is the equivalent of testing by the FDA. Some is, however, for example, the testing done by Underwriters Laboratories. So far, it seems, engineering's strict rules concerning conflict of interest seem to have protected it from the sorts of scandals medical research has suffered.

[68] Nevertheless, some guidance on conflict of interest in scholarship is available from the Association of American Law Schools, which requires that professors disclose any economic interest that they have in the subject matter of their scholarship. Insofar as professors are themselves members of their respective professions, they will be subject to the same conflict of interest rules and codes of conduct as their nonscholarly colleagues.

specific conflicts of interest (usually describing which conflicts will be prohibited, consentable, or allowable even without consent).

2. Compliance with each profession's codes of ethics depends—as the AICPA code of ethics says—"primarily on members' understanding and voluntary actions, secondarily on reinforcement by peers and public opinion, and ultimately on disciplinary proceedings, when necessary, against members who fail to comply with the Rules." In other words, the codes of ethics of all four professions are enforced in much the same way that the AMA enforces its code of ethics. They are not designed for use by state licensing boards.

3. Protecting against conflict of interest occurs not only at the level of the professional society and state licensing board. Some conflicts of interest constitute malpractice or breach of criminal law or civil regulation (e.g., the Sarbanes-Oxley Act and its regulations). Some failures to deal properly with conflicts of interest can have serious consequences for the professionals involved. Statutes and case law, however, generally sets a standard for conduct lower than that set by codes of ethics: law is designed to set minimum standards below which no member of the profession should fall, whereas codes of ethics are designed at least in part to set a higher standard (something closer to the best that can reasonably be expected of members of the profession). For many professions, the minimum standard with respect to conflict of interest has risen substantially over the last four decades. There is no reason to expect that trend to change anytime soon.

4. There is general agreement that professionals will find themselves in some conflict of interest situations even when all reasonable precautions have been taken to avoid them. When avoidance cannot reasonably be expected or has failed, censure attaches not so much to having a conflict of interest (except for prohibited relationships) as to a professional's failure to take proper steps to deal with it.

5. The conflicts of interest discussed in this paper can arise in at least three ways:

- The interests of two or more of a professional's current or former clients (or employers) can conflict and the professional can therefore be in a situation in which serving one client competently (for example, preserving confidential information) would mean not serving another client competently (that is, the professional is not able to use all of the information that he or she knows). This is a major concern for lawyers as well as for engineers.
- The financial, familial, or other interests or relationships of a professional can conflict with the interests of one or more clients (or employers) and thereby compromise judgment (a major concern for all four professions).

- The interests of a client (or employer) can conflict with the public interest and thereby risk compromising the quality of the professional's judgment (a major concern for CPAs, particularly when they conduct audits, but also a concern for architects working as adjudicators or making public statements and for engineers making public statements or working for or with government).

6. Each of the professions, as a general matter, understands that conflicts of interest can be created not only by financial considerations but also by other considerations, such as nonmonetary gifts, friendships, family relationships, and previous employment. The crucial question is always the known or suspected tendency of the fact in question to affect professional judgment adversely.

7. Each profession understands that conflict of interest is in part a threat to the trustworthiness (or reliability) of the profession as well as to judgments in specific cases. This is clear from the way in which the professions, each in a somewhat different way, address appearances. In general, members of these professions are supposed to avoid giving clients, employers, and the public even a plausible reason to suppose that they have an interest, relationship, or the like that might impair their objectivity (the reliability of their judgment).

8. Not all conflicts of interest are treated in the same way. We may distinguish three ways of treating them. The codes of ethics for each of the four professions begin with the instruction to avoid conflicts of interest. This general instruction is then modified or further refined by distinguishing between (1) conflicts of interest that must be avoided regardless of the specific circumstances (i.e., conflict of interest situations that are prohibited), (2) those that are permitted under certain circumstances following disclosure and, generally, that are accompanied by the informed consent of the client or other parties directly affected or some other management strategy, and (3) those conflicts of interest that are permitted because of their relative insignificance. Because clients or employers are often sophisticated individuals or businesses, they are capable of refusing consent or setting conditions for consent (once a conflict is disclosed). Modifiers such as "substantial" or "significant" as well as "direct" (in contrast to "indirect") indicate that not all conflicts of interest are of equal concern. The professions understandably attempt to focus their rules on interests that seem likely to have more than a minor impact on professional judgment or on trust in the profession.

9. Because so many conflicts of interest are either prohibited outright, require disclosure and consent, or are hard to manage, avoidance is, all else being equal, the preferred technique for dealing with conflict of interest. Avoidance is facilitated by certain practices; for example, a lawyer runs a "conflicts check" inside the firm before a new file is accepted. In all four

professions, the avoidance of a conflict of interest sometimes means forgoing personal gain or gain for a client or an employer, a fact that all four professions acknowledge. Avoiding conflict of interest certainly has costs (as well as benefits).

10. When the conflict of interest has not been avoided (for whatever reason and whether intentionally or unintentionally), various options to escape from or manage the conflict exist. Recusal is one option. For example, engineers who are members, advisors, or employees of a governmental department must withdraw from decisions in which they, their employers, or their clients have an interest. The engineer must comply with this ethical rule even if governmental regulation allows for disclosure and consent as an alternative way of managing the conflict. Despite the general requirement to avoid conflicts of interest, professionals can proceed despite a conflict of interest under specified circumstances. Generally, certain precautions must then be taken: (1) disclosure of the interest to the parties concerned (who can include current and former clients, current and former employers, and third parties), (2) the informed consent of these parties (although, occasionally, disclosure alone is sufficient), and (3) the implementation of additional management measures (for instance, the use of screens in law firms). The codes try to make clear when disclosure followed by consent (or disclosure alone) will be considered sufficient to preserve both the fact and the appearance of proper judgment (independence, loyalty to client, reliability, or the like). When proper judgment cannot be ensured, the conflict must be avoided, despite the advantages (to the professional, the professional's employer or client, or any other party) of accepting it.

11. Patterns of difference between (what lawyers call) "consentable" and "nonconsentable" conflicts of interest are sometimes difficult to discern (and, indeed, may be evolving). Overall, it seems that the more dependent that the client, employer, or public is on the professional and the less ability that the client, employer, or public has to manage the conflict, the more likely that consent, even after full disclosure, will not override the general prohibition of conflict of interest. In legal practice, for example, a typical nonconsentable conflict of interest arises if a lawyer undertakes the drafting of a will granting him or her a substantial gift from a client. A typical consentable conflict of interest arises if, for example, a lawyer bought a share in a hotel owned by a client (what lawyers call an "arm's-length" business transaction).

12. Instruction in understanding, identifying, and managing conflicts of interest is included in graduate education, licensing examinations, and (often) in mandated CPE for all of the professions evaluated here.

13. CPE in law, accounting, architecture, and engineering is provided by companies that are authorized by the relevant state-designated licensing boards or a national accreditation body to provide CPE. Individual pro-

fessionals must regularly complete a set amount of CPE, often including training in conflict of interest, to maintain their professional licenses. They or their employers pay the cost of the CPE, although some CPE courses are offered for free by local or national professional organizations.

Table C-1 summarizes the responses of the four professions discussed here to conflicts of interest.

TABLE C-1 Summary of the Responses of Four Professions to Conflicts of Interest

Conflict of Interest	Lawyers	Certified Public Accountants	Architects	Engineers
Gifts or rebates	Lawyers cannot solicit or prepare instruments to receive substantial gifts.	Gifts are prohibited unless the value is "clearly insignificant to the recipient."	Gifts cannot be accepted. Rebates are permitted only with the informed consent of all relevant parties.	Engineers cannot solicit or receive gifts or other valuable consideration.
Public speaking, speaking about professional issues	Not addressed.	Public speaking is not addressed, except to the extent that audits and attestations are public statements (conflict of interest management is very strict in such cases).	Architects must disclose any personal financial interests in public statements.	Engineers are forbidden from making statements on technical matters "that are inspired or paid for by interested parties," unless the engineer prefaces the statement with disclosure of the interest.
Financial or other relationships with client	Some fair financial relationships (business transactions, real estate, etc.) with a client are possible following disclosure and informed consent. Many personal relationships are nonconsentable.	Neither a CPA nor members of a firm can have direct or many indirect financial interests or familial interests in the client being audited. Restrictions on nonaudit services are offered during the time of audit.	Disclosure and consent are required if the client is not aware.	No contingent fee under conditions that could affect professional judgment is allowed. Disclosure and consent are required if the client is not aware.

Financial or other relationships with relevant (opposing) nonclients	No representation of opposing parties in litigation is allowed. Representation following disclosure and consent of both parties at other times is allowed.	Few restrictions.	Disclosure and consent of all interested parties are required.	Such relationships are generally prohibited. Exceptions (such as testifying in court as an expert witness) are allowed with full disclosure and consent.
Sponsorship of CPE	CPE is usually paid for by the lawyer or his or her firm.	CPE is paid for by the accountant or his or her firm. CPE is not approved if it is "devoted to the promotion of particular products or services."	AIA or NCARB provides CPE. CPE is paid for by the architect or the firm when it is not provided for free.	CPE is primarily required for a PE license, generally state certified. Most engineers are not required to take CPE, but whether it is required or not, it is generally paid for by the engineer or the employer.

D

How Psychological Research Can Inform Policies for Dealing with Conflicts of Interest in Medicine

*Jason Dana**

Physicians take an altruistic pledge to consider their patient's interests ahead of their own in clinical practice. Likewise, medical researchers have a professional obligation to conduct their research ethically in their search of truth. A conflict of interest is a set of circumstances that creates a substantial risk that professional judgment or actions regarding a primary interest will be unduly influenced by a secondary interest. Although the information in this report can be applicable to many types of conflict of interest, it focuses on financial conflicts of interest, which can occur when medical professionals interact with the pharmaceutical industry. For example, when physicians accept support for clinical research or continuing education programs, accept consultantships and appointments to industry-sponsored speakers bureaus, or have informal meetings with pharmaceutical sales representatives who buy lunch and bring drug samples, there is concern about the impact of these relationships on prescribing behaviors and professional responsibilities (Marco et al., 2006).

The purpose of this paper is to bring basic psychological research to bear on understanding financial conflicts of interest in medicine and effectively dealing with these conflicts. A particular focus will be research on self-serving biases in judgments of what is fair. This research shows that when individuals stand to gain by reaching a particular conclusion, they tend to unconsciously and unintentionally weigh evidence in a biased fashion that favors that conclusion. Furthermore, the process of weighing

* Jason Dana, Ph.D., is professor of psychology in the Department of Psychology, University of Pennsylvania, Philadelphia.

evidence can happen beneath the individual's level of awareness, such that a biased individual will sincerely claim objectivity. Application of this research to medical conflicts of interest suggests that physicians who strive to maintain objectivity and policy makers who seek to limit the negative effects of physician-industry interaction face a number of challenges. This research explains how even well-intentioned individuals can succumb to conflicts of interest and why the effects of conflicts of interest are so insidious and difficult to combat.

The section Unconscious and Unintentional Bias describes the psychological research on bias in more detail, and its relevance to financial conflicts of interest will be made clearer. The section Parallel Evidence in the Medical Literature then provides a brief review that demonstrates the correspondence between the findings from studies of conflicts of interest in the medical field and the findings from basic studies of bias in the field of psychology. The section Implications for Policies Dealing with Medical Conflict of Interest details for policy makers how approaches including educational initiatives, mandatory disclosure, penalties, and limiting the size or type of gifts can be informed by the psychological bias literature. The Methods and Limitations of the Data briefly addresses the propriety of applying psychological experiments to professionalism in medicine. Finally, a conclusions section summarizes what can be learned from the psychological literature.

UNCONSCIOUS AND UNINTENTIONAL BIAS

One intuitive view of financial conflicts of interest is that the physicians who are swayed by them are corrupt. Physicians have taken an oath to put their professional obligations first, so that if they are indeed influenced by private financial incentives, they have chosen not to uphold that oath. Although there may indeed be a minority of individuals who are fundamentally corrupt, most physicians certainly try to uphold ethical standards. This intuition is implicit in the guidelines set forth by the American Medical Association, the American College of Physicians, and the self-imposed guidelines of the Pharmaceutical Manufacturers Association, all of which stress that gifts accepted by physicians should primarily entail a benefit to patients and should not be of substantial value, suggesting that the temptation to provide or accept large or personal gifts is a concern. This view perhaps suggests that physician relationships with the pharmaceutical industry are problematic and can elicit hostility from some physicians. Understandably, most physicians see themselves as ethical people who would not place their objectivity for sale, and so they believe that they can be trusted to navigate these conflicts when dealing with industry. Compounding matters, many enticements from industry are of relatively small

financial value. This prompts responses that physicians are "above sacrificing their self-esteem for penlights" (Hume, 1990) or that if panelists on a scientific committee are influenced by receiving reimbursement for travel and expenses, someone "bought their opinions" and "they obviously come cheap" (Coyne, 2005).

This view is also compatible with an orthodox economic approach, which casts succumbing to conflicts of interest as the rational output of a cost-benefit calculation. In that case, solutions to problems of conflicts of interest would involve better monitoring and punishment, hopefully to the point at which ethical lapses would be too costly to indulge.

Evidence from psychology offers us a different view, one in which our judgments may be distorted or biased in ways of which we are unaware. Some of the most compelling evidence of bias comes in the domain of optimism about the self. There is, for example, much evidence that people engage in self-deception that enhances their views of their own abilities (Gilovich, 1991). One of the most oft cited and humorous examples of self-enhancement is found in a study that reported that 90 percent of people thought they were better drivers than the average driver (Svenson, 1981). Such biases have been dubbed "self-serving" (Miller and Ross, 1975) when they lead one to take credit for good outcomes and blame bad outcomes on external sources. Although an unrealistic optimism about the self is sometimes adaptive and healthy (Taylor and Brown, 1988), these biases can lead to judgments that are unwise or unjust in situations in which we are epistemically responsible for being correct.

Perhaps most relevant to the issue of financial conflicts of interest are well-known self-serving biases in the interpretation of what allocations are fair or just. A classic demonstration of self-serving bias in fairness comes from a study by van Avermaet (reported by Messick, 1985). Subjects were instructed to fill out questionnaires until they were told to stop. When the subjects finished, the experimenter left them with money that they could use to pay themselves and send in an envelope as pay for another subject who had already left. In four different conditions, the subject was told one of the following four different conditions: (1) the other subject had put in half as much time and had completed half as many surveys, (2) the other subject had put in half as much time but had completed twice as many surveys, (3) the other subject had put in twice as much time but had completed half as many surveys, or (4) the other subject had put in twice as much time and had completed twice as many surveys.

It is first interesting to note that almost everyone took the trouble to send the other person a share of the money, even though they were free to keep it all. It was not clear to the author that the rare cases of nonreturn were not due to a mistake or a lost envelope. Clearly, the subjects' sense of ethics served as a powerful constraint on their behavior: keeping all of the

money would be unjustifiably selfish and unfair because the other subject at least did similar work, so most subjects shared it. How they shared the money, however, provides an interesting insight into human nature. The subjects who worked twice as long and completed twice as much kept twice as much money, on average, a simple application of a merit principle to pay. The subjects kept more than half of the money, however, both under the condition in which they worked longer and completed less and under the condition in which they completed more work and did not work as long. Again, their behavior was consistent with a merit principle, but the principle chosen, on average, systematically favored the subject making the allocation. Finally, when the subjects completed only half as much work and worked only half as long, they did not, on average, give the other subject twice as much money. Instead, the subjects kept about half of the money, on average, consistent with a rule of equal division rather than merit.

What we can take away from the van Avermaet study is that most people are not unabashedly selfish; they have a sense of what is fair and tend to abide by it. Yet, that does not mean that judgments of fairness are not systematically biased to favor the self. When people are free to choose among competing principles of fair behavior, they tend to gravitate toward those principles that most favor their own interests. Other early experiments have similarly found that interpretations of fair allocations of pay are self-servingly biased (Messick and Sentis, 1979). One potential shortcoming of these experiments, however, is that they used a survey methodology. Thus, the subjects' self-interest was imagined, and they had no motivation to honestly report what they thought was fair. Thus, although it is apparent that the subjects had malleable interpretations of what was fair, it is not always clear whether these interpretations reflected a bias or, for example, a strategic effort on the part of the subjects. In that case, one wonders if the use of sufficient compensation would erase the effect.

A series of experiments by behavioral economists (Loewenstein et al., 1992; Babcock et al., 1995) addresses this problem through the use of real money incentives without deception and establishes that self-serving interpretations can arise as unwitting and unintentional biases. Simulating pretrial bargaining, Loewenstein et al. (1992) conducted bargaining experiments in which subjects were presented with case materials (depositions, police reports, etc.) from an actual law suit. The subjects were randomly assigned to the role of either the plaintiff or the defendant and were asked to negotiate a settlement in the form of a payment from the defendant to the plaintiff. At the outset, the experimenters gave the defendants a monetary endowment to finance the settlement, and the division of the endowment that the subjects agreed upon through bargaining was what they took home as pay. The longer that it took the parties to agree to a settlement, the more that both were penalized by having the endowment of money that

they were dividing shrink. If they failed to settle, the defendant's payment to the plaintiff, based on the smaller endowment size, was determined by a neutral judge who had reviewed all of the case materials. Before they negotiated, both the plaintiffs and the defendants were asked to predict how the neutral judge would rule in the case and were also paid for the accuracy of this prediction.

The subjects in this experiment had every incentive to be objective in seeking a settlement; if their demands were unreasonable, the pot of money would only shrink and ultimately the award would be determined by a neutral and informed party. If the subjects' estimates of a fair settlement were biased in a self-serving manner, however, they might be inclined to view the other party's offer as unjust and unacceptable. Indeed, the subjects were often unable to settle, to their own detriment. Direct evidence that the self-serving bias played a role in this failure to settle came in the form of the predictions of the judge's ruling. The plaintiffs' predictions of the judge's award to them were, on average, substantially higher than those of the defendants, even though the estimates were secret and had no bearing on the settlement and both parties were paid to be accurate in their estimates. Furthermore, the larger that the discrepancy between a particular plaintiff's and defendant's estimates was, the lower was their likelihood of settlement, and hence, they both left the experiment worse off in terms of payment. This evidence suggests that self-serving biases are unintentional because people are often unable to avoid being biased, even when it is in their best interest to do so.

In subsequent experiments that used the same paradigm (Babcock et al., 1995), the settlement rates were markedly improved by assigning subjects their roles only after they had read the transcripts. In this way, any motivation to interpret evidence as favorable to one side over another while the subjects were reading and evaluating the materials was removed. Without the subjects having a self-interested conclusion to reach, interpretations of fairness, as measured by predictions of the judge's ruling, looked more like those of a neutral third party than an interested party. In principle, of course, these judgments were exactly like a third party's judgment. The finding is important, however, because these subjects still had the same bargaining task as in the earlier experiments. Thus, one cannot conclude that the majority of failures to settle were due to the subjects being overly competitive or having a poor strategy. Rather, manipulations targeting the objectivity of the fair ruling judgment increased the settlement rates. This finding suggests that self-serving biases work by way of distorting the way that people seek out and weigh information when they perceive that they have a stake in the conclusion.

The motivated reasoning displayed by the subjects in the study of Loewenstein et al. (1992) confirms the general findings from social psychol-

ogy research. Gilovich (1991) describes the different evidential standards that people typically use to evaluate propositions that they wish to be true versus propositions that they wish to be false. When they evaluate an agreeable proposition, people ask, "Can I believe this?" When they evaluate a disagreeable position, people ask, "Must I believe this?" The former question implies a more permissive evidential standard because it requires the decision maker only to seek out confirmatory evidence, whereas the latter question implies that the proposition must survive a search for disconfirming evidence.

These different evidential standards are exemplified by studies that use a variant of the classic Wason card selection task (Wason, 1966). The Wason task asks subjects to test an abstract logical rule by choosing which pieces of information that they want to be revealed to them. An overwhelming majority of subjects, even those with high levels of formal education, fail to reason through this task properly. The most common mistake that they make is selecting information that could confirm the rule but that is useless for testing it while failing to select information necessary for testing the rule because it could disconfirm it.

Dawson and colleagues (2002) modified the Wason card selection task by having subjects sometimes test hypotheses that they did not want to believe, such as those that implied their own early death. Providing motivation not to believe in this manner improved the subjects' performance over that in situations in which the subjects were testing nonthreatening or agreeable hypotheses. This finding is interesting because it shows not only that people approach the problem differently when the hypothesis is agreeable or disagreeable but also that the proper motivations can lead them to solve problems that they are otherwise incapable of solving. Thus, motivated reasoning appears to operate at a preconscious level.

The "can I?" versus "must I?" distinction in the motivated evaluation of evidence could be applied to thinking in many financial conflict of interest situations. For example, a physician may evaluate evidence that a particular treatment is effective. If that physician stands to make money by prescribing that treatment, the motivation of financial gain may make his or her evaluation of the drug's effectiveness hold to a weaker evidential standard.

In further studies on the self-serving bias, Babcock et al. (1995) attempted to reduce bias by educating subjects, describing to them the behavioral regularities of bias that lead to disagreement, and testing the subjects to make sure that they understood. This intervention, on average, had little success in improving settlement rates. It did help the subjects recognize bias, but mostly in their negotiating opponents rather than in themselves. Moreover, those subjects who did concede that they might be somewhat biased tended to drastically underestimate how strong their bias was. This

finding suggests not only that bias is unconscious but also that conscious attention alone cannot be expected to remove bias.

This finding—that teaching people about bias makes them recognize it in others but not themselves—has since been confirmed and extended. Several studies of the "bias blind spot" (Pronin et al., 2002) have found that for any number of cognitive and motivational biases that the researchers can describe, subjects will, on average, see themselves as less subject to the bias than the "average American," classmates in a seminar, and fellow airport travelers. That is, the average subject repeatedly sees himself or herself as less biased than average, a logical impossibility in the aggregate that suggests that self-evaluations of bias are systematically biased. Furthermore, experiments have shown that when people rate themselves as being less biased than they rate the average person, they subsequently tend to insist that their ratings are objective (Pronin et al., 2002; Ehrlinger et al., 2005). Much like in the study of Loewenstein et al. (1992), this insistence persists even after the subjects read a description of how they could have been affected by the relevant bias. Why do people recognize less bias in themselves than in others, and why does education not make this bias go away?

Further studies of the bias blind spot (Ehrlinger et al., 2005; Pronin and Kugler, 2007) have identified a mechanism behind this behavior that they term an "introspective illusion." Being privileged to their own thoughts, people use introspection to assess bias in themselves. Because biases like the self-serving bias operate below the level of conscious awareness, they can "see" that they are not biased; at least, they have no experience of bias and so conclude that they are not biased. When they assess bias in others, however, people do not have the privilege of knowing what a person thought and must rely on inferences based on the situation. If another's behavior is consistent with a bias, people will often conclude that the other is biased. Learning about various cognitive and motivational biases can exacerbate these "I'm better-than-average" effects. People will often still hold that they are not biased because they "know" their own thoughts, but they will now know what to look for in a situation that could bias others. The bias blind spot gives us one way of understanding why such strong disagreements can take place over whether conflicts of interest are problematic.

In summary, psychological research suggests that people are prone to having optimistic biases about themselves. Judgments about what is fair or ethical are often biased in a self-serving fashion, leading even ethical people to behave poorly by objective standards. Self-serving bias is unconscious and unintentional, and people often fall prey to it even when they do not want to do so and they do not know they are doing it. The bias works by influencing the way in which information is sought and evaluated when the decision maker has a stake in the conclusion (financial or otherwise). The bias thus leads to the use of more lax evidentiary standards when the deci-

sion maker wants to believe something than when the decision maker does not. Teaching about egocentric biases like the self-serving bias does little to mitigate them because when people examine their own thinking, they do not experience themselves as being biased. People do learn to look for bias in others, however, which can lead them to conclude that others are biased while they themselves are not.

PARALLEL EVIDENCE IN THE MEDICAL LITERATURE

Medical research on conflicts of interest—such as research on attitudes about or the influences of gifts to physicians from industry—has not set out to research whether unintentional bias exists. The findings in the medical literature, however, correspond nicely with the findings from basic psychological studies of bias. This correspondence serves as support for the idea that the model of unconscious and unintentional bias can help us understand conflicts of interest in medicine.

Most prominently, although some physicians may admit to the possibility of being influenced, physicians typically deny that they are influenced by interactions with and gifts from industry, even though research suggests otherwise (Avorn et al., 1982; Lurie et al., 1990; Wateska, 1992; Caudill et al., 1996; Orlowski and Gibbons et al., 1998; Adair and Holmgren, 2005). The question is whether these denials by and large reflect a sincere belief in one's objectivity. Accumulating evidence suggests that physicians believe that other physicians are more likely to be influenced by gifts than they themselves are (McKinney et al., 1990).

A study of medical residents (Steinman et al., 2001) found that 61 percent reported that "promotions don't influence my practice," while only 16 percent believed the same about other physicians. Findings that residents in general believe that others are more likely to be influenced by interactions with industry than they are have been confirmed in a more recent review (Zipkin and Steinman, 2005). Morgan et al. (2006) found that for all of four different gifts, ranging in size from a drug sample to an offer of a well-paid consultancy based only on prescribing volume, physicians rated themselves as less likely, on average, to be influenced by their acceptance of a gift than their colleagues. Even medical students see gifts of equal value as being more problematic for other professions than their own (Palmisano and Edelstein, 1980).

There is even some direct evidence that physicians do not appreciate industry's influence on them. Orlowski and Wateska (1992) tracked the pharmacy inventory usage reports for two drugs after the companies producing the drugs sponsored 20 physicians at their institution to attend continuing medical education seminars. The rates of use of the drugs described at these seminars increased, both in time series analysis of the rate

of use of the drugs at the institution and in comparison with the national average rate of use during the same period. However, before they attended the seminars, all but one of the physicians denied that the seminars would influence their behavior. Being asked about bias should make physicians more aware of the potential of bias entering into the seminar, yet this did not prevent the seminar from apparently having an impact on the physicians' decisions.

A retrospective study (Springarn et al., 1996) tracked house staff who attended a grand rounds sponsored by a pharmaceutical company and found that they were more likely to indicate that the company's drug was the treatment of choice than were their colleagues who had not attended the session. Interestingly, these same physicians were often not even able to recall the sponsored grand rounds, so they were not consciously aware that it had any influence on their decisions.

If conflicts of interest in medicine can indeed be understood as unconscious and unintentional, how might that affect how policy makers approach dealing with them?

IMPLICATIONS FOR POLICIES DEALING WITH MEDICAL CONFLICTS OF INTEREST

Short of eliminating conflicts of interest altogether, there are several interventions that universities, professional societies, and other policy makers frequently employ to guard against the inappropriate influence of industry on medical practice and research. These interventions may be implicitly predicated on the view that succumbing to conflicts of interest is a conscious choice, however, and thus they may have limited or surprising effects if physicians are subject to unconscious bias. The psychological research reviewed here suggests that policy makers may wish to be cautious in their expectations of success for these policies, as they are not tailored to deal with unconscious bias. Policy makers may also wish to consider some possible perverse consequences that can result from using these interventions.

Education

Educational initiatives can be thought of as taking two forms: substantive education in ethics and education aimed specifically at describing and explaining institutional policies and enforcement and individual responsibilities.

Perhaps the biggest barrier to the effectiveness of teaching about bias specifically is the bias blind spot. Certainly, some value exists in teaching physicians about potential conflicts of interest when they are dealing with industry. Simply knowing about the potential for bias, however, does not

prevent one from being biased. The bias blind spot (Pronin et al., 2002) research described earlier suggests that simply teaching about biases is more likely to help physicians recognize bias in other physicians than in themselves. The blind spot suggests one reason why many physicians deny that they are personally influenced by gifts from industry, despite evidence that gifts and interactions do influence decision making (e.g., Orlowski and Wateska, 1992; Caudill et al., 1996; Wazana, 2000).

Even if people are taught about bias, they are still prone to it. Navigating relationships with industry and accepting gifts while remaining completely objective, then, is not a simple imperative that physicians can be easily trained to follow. Indeed, the research of Loewenstein et al. (1992) suggests that knowing about bias is not sufficient to prevent it even if one is determined to be objective. Thus, recommendations for physicians, such as "If nominal gifts are accepted, make certain that they do not influence your prescribing or ordering of drugs" (Marco et al., 2006), are not practical. Perhaps an effective use of education is to help physicians recognize which relationships lead to bias so that those relationships may be preemptively avoided.

There is, however, some indication that teaching specifically about the unconscious aspect of bias could help in one respect (Pronin and Kugler, 2007). That is, limited evidence suggests that such teaching reduces the gap between perceptions of bias in self and others, and thus, education could reduce the sharpness of disagreement about whether bias exists.

Education aimed at conveying institutional guidelines about the receipt of gifts has produced mixed results. On the one hand (Brett et al., 2003; Agrawal et al., 2004; Schneider et al., 2006), after successfully completing such educational initiatives, residents can identify practices that are appropriate and inappropriate consistent with institutional guidelines. On the other hand, these behaviors, which are mostly of a self-report nature on a survey, do not suggest much about how residents will behave, and several authors have raised questions about how long lasting these effects are (Agrawal et al., 2004; Schneider et al., 2006; Carroll et al., 2007). Furthermore, it seems that there are also some perverse effects from familiarizing students with how to interact with industry. Although theirs was not a study about education as such, Fitz et al. (2007) found that even though clinical and preclinical students had the same knowledge about industry, their attitudes about the appropriateness of gifts could still differ, with clinical students far more likely to believe that accepting gifts is appropriate. Hyman et al. (2007) found that although students generally believed that they were not educated enough to deal with industry, students who reported feeling better educated about the pharmaceutical industry were less skeptical about the industry and were more likely to view interactions with the

pharmaceutical industry as appropriate. We cannot tell from this sort of self-reporting what the exact nature of this education was.

When guidelines are voluntary, many physicians interact with industry without familiarizing themselves with the guidelines. Morgan et al. (2006) found that although most physicians had contact with the pharmaceutical industry—as evidenced by the fact that more than 93 percent of them had received drug samples—less than two-thirds were aware of the guidelines for interaction with the industry set forth by the college to which the physician belonged, and only one-third were familiar with the guidelines of the American Medical Association. Therefore, requiring education on the content of the guidelines might be a useful point of intervention if many physicians are unaware of them.

Penalties

Deterring bias through punishment is more likely to be effective if people are knowingly influenced by financial considerations. The psychological research reviewed above, however, suggests that bias due to conflicts of interest can often arise unconsciously and unintentionally, such that people cannot overcome bias even when it is in their best interest to do so. One concern, then, is that aligning self-interest with guidelines through punishment may not be as effective as we would wish.

Perhaps even more difficult, though, is establishing whether a case of bias exists. Research identifies statistical evidence of bias by analyzing aggregated sample information, ideally against some control sample. That is much different from establishing that an individual is biased. Law typically requires that each case be considered individually, but without adequate comparisons, it cannot be established that a physician's beliefs and practices were unduly influenced by nonproscribed relationships with industry, as opposed to being genuine and objective. The prospect of penalties can, of course, help deter cases of blatant corruption and may encourage conformance to policies requiring disclosure of financial interests. The vast majority of industry's influence on physicians, however, is likely of a more nuanced nature, the result of basically ethical individuals being subtly biased. There are thus serious barriers to effective penalties.

Disclosure

One common policy response is to require physicians with potential conflicts of interest to disclose them to those whom they advise. In this way, patients or those hearing a presentation can consider the potential for bias, and the physician may perhaps be mindful of this when he or she enters into relationships with industry. For several reasons, this policy is

problematic, and disclosure may be largely ineffective by itself and in some instances could have perverse effects.

As an example, consider a physician who advises a patient to pursue some treatment and discloses a possible financial conflict of interest. How should the patient rationally discount the physician's advice in light of the disclosure? Even if the physician has private incentives, it does not follow that the advice is not genuine. Furthermore, even if the physician is likely to be biased, that does not mean that the advice is incorrect. Often it will be the case that the patient can either take or ignore the physician's advice, and the disclosure does little to alleviate uncertainty. In addition, patients are in often a vulnerable situation with a need to trust their physicians.

Forcing the physician to disclose a possible conflict of interest may also have perverse effects. For example, now that the disclosure has taken place, the physician may expect that the patient will be skeptical and respond by making the message more forceful, a sort of strategic exaggeration (Cain et al., 2005). If patients metaphorically cover their ears, physicians who believe that they must get their message across will yell louder. Although the exaggerated advice may perhaps be discounted, it may still be followed.

Decades of psychological research on anchoring and insufficient adjustment has shown that when judgment begins from even a random anchor that people know is incorrect, judgment will not be adjusted sufficiently far from the anchor. For example, experimenters ostensibly spun a wheel of fortune that actually always landed on 65 or 10 and then asked two questions (Tversky and Kahneman, 1974): "Is the proportion of African nations in the United Nations less than or greater than (10/65)?" and "What is the proportion of African nations in the United Nations?" The median response when the wheel was spun to 10 was much lower (25) than the median response when the wheel was spun to 65 (45). Although the subjects did adjust away from the implausible anchors that they were given, they were still affected by those anchors, even though they knew that the values of the anchors were irrelevant. This effect is one of the strongest in the judgment and decision-making literature. One implication, then, is that even if advisees know that the advice is exaggerated, they will still be influenced by it.

An experimental study of the effects of disclosure has found just that (Cain et al., 2005). Experimental "advisers" were asked to give advice on the worth of a jar of coins that they could get close to and hold. Their advisees earned money by accurately guessing the value in the jar, whereas the advisers earned money by inducing higher guesses from the advisee. Perversely, when advisers had to disclose these incentives, advisees were made significantly worse off. This effect was in part due to the fact that the advisers exaggerated their advice in light of disclosure, whereas the advisees were unable to sufficiently adjust down from the inflated advice.

Limiting Gifts by Size or Use

Policies on gifts often suggest that any gifts accepted by physicians individually should primarily entail a benefit to patients and should not be of substantial value. Certainly, small gifts are preferable to large gifts. Because bias is unintentional and not a matter of corruption, however, small gifts may still produce results and therefore should not be assumed to be benign. Katz and colleagues (2003) reviewed and synthesized a sizeable body of social science literature that suggests that small gifts induce feelings of reciprocity, get a message across by mere exposure (pens, notepads, etc.), and can be effective in changing behavior. Even the sheer ubiquity of trinkets like pens and notepads suggests that this is true. Why else would profit-minded entities who conduct market research on their practices continue to supply them if their efforts did not fetch a return?

The ethical distinction of a gift having versus not having a primary patient benefit, though intuitively appealing, may also be meaningless. The distinction may reveal a lack of appreciation of the fungibility of money, as first pointed out in Thaler's treatise on mental accounting (1980). For example, if a physician receives a $100 anatomical model, then he or she does not have to buy it, and that frees up $100 to buy something else for themselves, such as a golf bag or a nice dinner. This situation is consequentially equivalent to the company giving the physician an inappropriate monetary gift, even though our intuitions may tell us that the latter is much worse because we place it in the "extravagance" account rather than the "patient care" account. The research evidence cannot tell us what is ethical, but the policy maker should keep in mind that any gift is still a gift, because the economic value is exchangeable whether it is received in the "extravagance" account or the "patient care" account.

Even gifts with clear patient benefit—like the ubiquitous drug sample—have been associated with problems. Physicians and their staff frequently end up using the samples that are intended for patients (Westfall et al., 1997), which can also provide a covert means for pharmaceutical representatives to supply physicians with free medications for personal or family use. Furthermore, there is evidence that physicians with access to drug samples will end up prescribing more advertised, expensive drugs in the future (Adair and Holmgren, 2005), so that these gifts can also drive up health care costs.

Limitations on the size and use of gifts may not be a bad policy in terms of limiting corruption, but there may still be influence associated with gifts that are permitted under many current policies.

METHODS AND LIMITATIONS OF THE DATA

A common problem with data from psychology experiments is that they overly rely on college undergraduates as a sample of convenience. This problem is perhaps serious in that it raises questions about the generality of the results. Whereas care should be used in extrapolating the findings of experiments conducted with populations composed entirely of college students, there are reasons to take the findings on unconscious bias seriously. First, the phenomenon in question is less likely to suffer from a lack of generality because it is proposed to be a function of the human brain and is not dependent much on context or experience. Because the brain development of college students has mostly been completed, these findings should hypothetically generalize to older adults. Second, absent a theory of how physicians differ from other college students, there is no reason to suspect that they will not be subject to unconscious bias. As support for this idea, the applicability of the psychological research to other professionals (auditors) was also drawn into question when findings of unconscious bias were suggested as a cause for financial malfeasance. Yet, when a study was done with a sample of actual auditors (Moore et al., 2006), the findings of bias were much as what would be expected in the laboratory with college students.

Perhaps more importantly, the types of decisions and incentives studied in psychological experiments are considerably different in quality from the treatment decisions made by physicians who have relationships with industry. The intention of this paper is not to overstate the similarity between the two. That does not mean, however, that the concept of unconscious bias does not raise valid concerns over how to deal with conflicts of interest. Indeed, the fact that the findings from research on bias in medicine (and other professions) mirror the findings from the psychological research on bias suggests that the concept of unconscious bias is a good tool to be used to obtain an understanding of conflicts of interest in medicine.

CONCLUSIONS

Psychological research tells us that people are prone to having optimistic biases regarding themselves, including judgments about whether their own behavior is objective. A large body of literature has shown that these biases are unconscious and unintentional: people fall prey to them even when they do not want to or think that they do. Although it may seem to be intuitively and easily recognized that people are biased in assessing themselves, the fact that these biases are often unconscious and unintentional is not intuitive and is largely underappreciated. The findings of research on the influence of industry on medical practice corresponds closely to the

findings of psychological research, suggesting that we might view the biasing effect of conflicts of interest in medicine to result from an unconscious and unintended bias.

Although this view is kind to physicians, in that it allows the biased individual to be understood as basically being well intended, it is also a cause for concern, in that research suggests that such unconscious biases are quite difficult to combat on the large scale. For example, teaching about egocentric biases does not mitigate them because when we examine ourselves, we do not experience ourselves as being biased. This distinction is not merely an academic argument about human nature; several policies that we expect to combat the effects of conflict of interest may not be effective if unconscious bias is an important factor, and the effects of these policies could even be perversely counterproductive. Policy makers may benefit from recognizing and accommodating a more psychologically nuanced view of conflicts of interest in their interventions.

E

The Pathway from Idea to Regulatory Approval: Examples for Drug Development

*Peter Corr and David Williams**

IN BRIEF: FROM IDEA TO MARKET AND CLINICAL PRACTICE

For small-molecule drugs, the path to a marketed drug involves a long and exhaustive journey through basic research, discovery of the medicine, preclinical development tests, increasingly complicated clinical trials with humans, and regulatory approval by the Food and Drug Administration (FDA). Several years—usually 10 to 15—and hundreds of millions of dollars later, under the best of circumstances, a new drug will be approved for marketing. Because of its complexity, drug discovery and development is widely recognized as one of the most financially risky endeavors in all of science and a major challenge for the biomedical industry. Much of this cost comes from failures, which account for 75 percent of the total research and development costs. Although these failures are disappointing and costly, they still contribute to the body of knowledge on disease processes. Academic health centers and research institutions play major roles in defining the targets applicable for small molecules and carrying out the clinical trials that are needed. The discovery and development process for therapeutic proteins or biologics is similarly long and difficult, and success is far from certain. Biologics are derived from living sources, including humans, other animals, bacteria, and viruses. From these sources come products such as vaccines and monoclonal antibodies, which also are regulated by the FDA. Academic health centers and research institutions have led the development of many biological agents, many of which have been successfully codeveloped with pharmaceutical and biotechnology companies.

* Peter B. Corr, Ph.D., and David A. Williams, M.D., are members of the Committee on Conflict of Interest in Medical Research, Education, and Practice.

Medical devices include a range of technologies, from surgical gloves, syringes, and thermometers to sophisticated prosthetics, imaging equipment, artificial heart valves, and electronic neurostimulators. Reflecting this diversity, the path from idea to product development for medical devices can be quite variable and quite different from that for drugs and biologics. The same is true for the extent of collaboration among academic, industry, and government researchers. Before they can market complex devices, device manufacturers must seek either premarket clearance (which is most common and which generally does not require clinical data) or premarket approval (which is required for only a small number of devices—often implanted devices—and which does require clinical data) from the FDA. As is the case for drugs, obtaining premarket approval is a complicated process that can take many years. For complex medical devices, the research team may include physicists, materials scientists, engineers, and mathematicians, as well as biologists and physiologists. Physicians often play a critical role in defining the needs for devices and the initial testing of prototypes in human clinical trials. In some cases, the basic idea for important medical devices can come from individuals who are not involved in basic or clinical research. For example, the idea (and crude first model) for a device to drain the buildup of cerebrospinal fluid in individuals with hydrocephalus came from a self-described mechanic who was the parent of an affected infant (Baru et al., 2001).

The following sections briefly describe the sequence of events for small-molecule drugs from concept to a marketed product. Figure E-1 (developed by the authors) depicts the process in graphic form for each of the following seven sections. (A more thorough review of the research and development process for small molecules, therapeutic proteins, vaccines, medical devices, and diagnostics can be found at www.rdguide.org.)

BASIC RESEARCH: THE IDEA

Long before a new drug can even be imagined, scientists are working to gain a basic understanding of a disease or of specific normal chemical pathways that are subverted in an abnormal cell. This research might be conducted in academic laboratories and research institutes around the world, and some of it is paid for by industry. Industry also plays a large role in the development of novel technologies, such as new approaches to sequencing of the human genome.

Along the road toward developing new medications, researchers have to acquire a basic understanding of bacterial, animal, and human genomes. They study which genes are involved in specific diseases. They also look at how gene products—or proteins—contribute to the derailments in cellular processes that result in the initiation or maintenance of a disease.

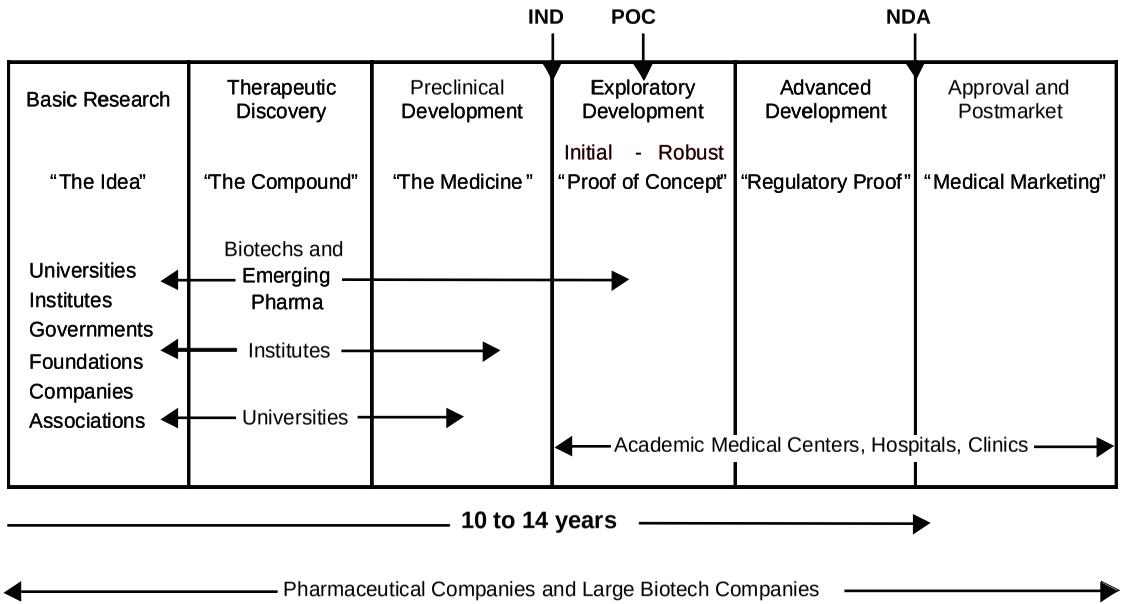

FIGURE E-1 Defining biomedical research from idea to market. IND = Investigational New Drug application; POC = proof of concept; NDA = New Drug Application; Pharma = pharmaceutical companies. SOURCE: Adapted from Corr, 2008.

In a kind of medical reconnaissance mission, biologists seek out and identify targets that might be attacked with a new drug. These targets are proteins, as well as the genes that define how those proteins are structured. Either may play a role in the onset or progression of a particular disease.

Until recently, researchers were limited to studying the biology (the function or the structure of molecules and cells) of only about 500 target proteins or genes. Now, with scientific advances, such as knowledge of the sequence of the human genome, the number of available biological targets has soared. Despite these gains, however, researchers still know very little about the role that many of these new targets play in causing or maintaining diseases.

Once researchers have identified a target, they then validate them by determining whether the target is relevant to the disease that they are studying. They must then determine if a drug could affect the target enough to alter the course of the disease. To do this, they use biochemical, cellular, or animal models to validate the biological mechanism of the target gene or protein.

Box E-1 summarizes an example of successful, extended, and complex collaboration that involved scientists from the National Institutes of Health as well as academic and industry scientists. Chapter 4 of the committee report cites additional examples.

Searching for Compounds

When a potentially relevant target for an identified disease is validated, chemists then mount a massive search for chemicals that might modify the target or targets. They screen vast compound libraries to develop a list of potential chemicals that might some day become a new medicine. This sophisticated process can be divided into three distinct steps: (1) development and maintenance of large compound libraries, (2) specific assay development, and (3) high-throughput screening.

Assays are analyses that quantify the interaction of the biological target and the compound that the researchers are investigating. They also might measure how the presence of the compound changes the way in which the biological target behaves.

The chemical compounds tested in these assays are maintained in large compound libraries, some of which contain more than 5 million chemicals. Products from natural sources like plants, fungi, bacteria, and sea organisms can be integrated within compound libraries. Most compounds, though, are derived through the use of chemical synthesis techniques, in which researchers create chemical compounds by manipulating chemicals. They might also use combinatorial chemistry, in which researchers create

BOX E-1
Case Example of Successful Collaboration in Drug Discovery and Development

In 2002, the biotechnology company Sugen and the Salk Institute published the human kinome, a subset of the human genome (Manning et al., 2002). Kinases regulate proteins and, in turn, have multiple functions in cells in both the normal and the disease states. On the basis of that work, scientists now know that there are 518 kinases in humans. These findings have revolutionized the approach to the inhibition of these kinases by drugs used to treat cancer and other diseases and that are currently on the market.

Elsewhere, researchers knowledgeable about patients with severe combined immunodeficiency disease (popularly referred to as the "bubble boy syndrome") had identified these patients as having mutations within the JAK-3 kinase, which suggested that a possible mechanism for affecting the deficiency of the immune system could be achieved through a JAK-3 inhibitor (Russell et al., 1995). This research was done at the National Institutes of Health.

Industry scientists at Pfizer spent several years discovering a compound that is active against JAK-3. The goal was to find a compound that would not block JAK-1 or JAK-2 kinase but that would be effective as an immunosuppressant by specifically and partially blocking JAK-3 without causing severe side effects.

Pfizer focused first on the drug's role as a potential antirejection drug for patients who have received an organ transplant. It collaborated with the transplant center at Stanford University to conduct studies with primates, with promising results (see, e.g., Borie et al. [2004]). The drug is being tested with human transplant recipients. It is also being investigated as a treatment for rheumatoid arthritis (see, e.g., Changelian et al. [2008] and Stanczyk et al. [2008]).

new chemical compounds in large masses and test them rapidly for desirable properties.

Testing of the expanding number of available biological targets against millions of chemical entities requires some highly sophisticated screening methods. Researchers use robotics, for example, to simultaneously test thousands of distinct chemical compounds in functional and binding assays. Many times, academic researchers with expert knowledge of specific pathways may guide the development of assays in collaboration with industry.

The chemical compounds identified through this kind of screening can provide powerful research tools that help provide a better understanding of biological processes. This, in turn, may lead to new targets for potential drug discoveries.

The purpose of this chemistry stage is to refine the compound. Hundreds and possibly thousands of related compounds may be tested to determine if they have greater effectiveness, less toxicity, or improved pharmacological behavior, such as better absorption after a patient takes the drug orally.

To optimize the molecules being investigated, scientists use computers to model the structure of the lead compounds and how they link to the target protein. This approach to structure-based design is known as in silico modeling (the word "silico" refers to the silicon technology that powers computers). This kind of structural information gives chemists a chance to modify the molecules or compounds selected in a more rational way. Lead optimization produces a drug candidate that has promising biological and chemical properties for the treatment of a disease.

The drug candidate is then tested for its pharmacokinetic behavior in animals, including its gastrointestinal absorption, body distribution, metabolism, and excretion. It is also tested for its pharmacodynamics, which refers to the relative effectiveness of the molecule.

Preclinical Studies: The Medicine

Once a single compound is selected, preclinical studies are performed to evaluate a drug's safety, efficacy, and potential toxicity in animal models. These studies are also designed to prove that a drug is not carcinogenic (i.e., it does not cause cancer when it is used at therapeutic doses, even over long treatment intervals), mutagenic (i.e., it does not cause genetic alterations), or teratogenic (i.e., it does not cause fetal malformations). Because a patient's ability to excrete a drug can be just as important as the patient's ability to absorb the drug, both of these factors are studied in detail at this stage of preclinical development.

Preclinical studies also help researchers design proposed Phase I studies to be conducted with human. For example, preclinical studies with animals help determine the initial dose to be evaluated in the clinical trial and help identify safety evaluation criteria. The latter include factors such as patient signs and symptoms that should be monitored closely during clinical trials.

The result of work at this stage is a pharmacological profile of the drug that will be beneficial long into the drug's future. Researchers can use the profile to develop the initial manufacturing process and pharmaceutical formulation to be used for testing with humans. Industry has particular strengths in these areas, and most development efforts at this stage are based in biotechnology or pharmaceutical companies. They can also use specifications assigned in this stage to evaluate the chemical quality and purity of the drug, its stability, and the reproducibility of the quality and

purity during repeat manufacturing procedures. At this stage, and before testing with humans begins, an Investigational New Drug (IND) application is filed with the FDA. If the IND application is approved, then clinical trials can begin.

Phase I Clinical Trials: Safety

Phase I trials are the first time that a drug is tested in humans. These trials may involve small numbers (20 to 100) of healthy volunteers, or they may include patients with specific conditions for which targeted pathways have been identified as potentially relevant to the disease under study. A Phase I study may last for several months. The focus of a Phase I study is the evaluation of a new drug's safety, the determination of a safe dosage range, the identification of side effects, and the detection of early evidence of effectiveness if the drug is studied in patients with disease, for example in patients with cancer. From Phase I clinical trials, researchers gain important information about

- the drug's effect when it is administered with another drug (the effect is often unpredictable and sometimes results in an increase in the action of either substance or creates an entirely new adverse effect not usually associated with either drug when it is used alone);
- the drug's pharmacokinetics (absorption, distribution, metabolism, and excretion) to better understand a drug's actions in the body;
- the acceptability of the drug's balance of potency, pharmacokinetic properties, and toxicity or the ability of the drug to zero in on its target and not another biological process; and
- the tolerated dose range of the drug to minimize its possible side effects.

Phase II Clinical Trials: Proof of Concept

In Phase II clinical trials, the study drug is tested for the first time for its efficacy in patients with the disease or the condition targeted by the medication. These studies may have up to several hundred patients and may last from several months to a few years. They help determine the correct dosage, common short-term side effects and the best regimen to be used in larger clinical trials. This usually begins with Phase IIa clinical trials, in which the goal is to obtain an initial proof of concept (POC). The POC demonstrates that the drug did what it was intended to do, that is, interacted correctly with its molecular target and, in turn, altered the disease. Phases I and IIa are sometimes referred to as "exploratory development." The Phase IIb

trials are larger and may use comparator agents and broader dosages to obtain a much more robust POC.

Phase III Clinical Trials: Regulatory Proof

Phase III clinical trials are designed to prove the candidate drug's benefit in a large targeted patient population with the disease. These trials confirm efficacy, monitor side effects, and sometimes compare the drug candidate to commonly used treatments. Researchers also use these clinical trials to collect additional information on the overall risk-benefit relationship of the drug and to provide an adequate basis for labeling after successful approval of the drug.

Phase III studies are conducted with large populations consisting of several hundred to several thousand patients with the disease or the condition of interest. They typically take place over several years and at multiple clinical centers around the world. These studies provide the proof needed to satisfy regulators that the medicine meets the legal requirements needed to be approved for marketing. The study drug may be compared with existing treatments or a placebo. Phase III trials are, ideally, double blinded; that is, neither the patient nor the researcher knows which patients are receiving the drug and which patients are receiving placebos during the course of the trial. Phase III trials are usually required for FDA approval of the drug. If the trials are successful, then a New Drug Application is submitted to the FDA. The process of review usually takes 10 to 12 months and may include an advisory committee review, but such a review is at the discretion of the FDA.

Phase IV Clinical Trials: Marketing and Safety Monitoring

Phase IV trials are studies conducted after a drug receives regulatory approval from the FDA. They may be used primarily for medical marketing. In some cases, the FDA may require or companies may voluntarily undertake postapproval studies to generate additional information about a drug's long-term safety and efficacy, including its risks, benefits, and optimal use. These studies may take a variety of forms, including studies that use data from the administrative databases of health plans as well as observational studies and additional clinical trials.

Postapproval trials may also be designed to test the drug with additional patient populations (e.g., with children), in new delivery modes (e.g., as a timed-release capsule), or for new uses or indications (i.e., for the treatment of a different medical condition). Because these postapproval trials are intended to provide the basis for FDA approval of further uses or

delivery modes, they must meet the same standards as the Phase III trials conducted for initial approval.

Model for Broader Disclosure

This appendix has two parts. The first is a proposal by three committee members for a model for broader disclosure of financial relationships and conflicts of interest than is presented in the committee report. The second is a response by the other committee members.

I. A PROPOSED MODEL FOR BROADER DISCLOSURE

Lisa A. Bero, Robert M. Krughoff, and George Loewenstein

We believe that the recommendations in Chapter 3 regarding disclosure of financial relationships or conflicts of interest would be greatly improved if they explicitly called for more extensive and standardized public disclosure by researchers, physicians, and senior officials of institutions. We believe that—with the help of interpretation by the press, public-interest groups, researchers, health care consultants, patient representatives, and other information intermediaries—expanded disclosure would provide important information for physicians, patients, researchers, health plans, regulators, policy makers, financial donors, and others who rely on research, practice guidelines, educational programs, and the quality and efficiency of medical care.

We believe that the recommendations should be extended to a "broader-disclosure model" in which

- The consensus-development process described in Recommendation 3.3 would not only set out the standardized content, formats, and procedures for disclosure to institutions but also design a secure national

online database system that could be used to report the same information to appropriate institutions and to the public.

- The consensus-development process would set out minimum standards as to the data elements that must be reported by people in specific roles (such as physician researchers and hospital administrators) to their institutions and would allow institutions to have higher standards if they so choose.
- Each institution would require that any information on financial relationships or conflicts of interest that must be reported to it—or at least all information included in the consensus-defined minimum standards—also be made available to the public through the online system.

We envision the broader-disclosure model working as follows:

- The first time that a person was required to report information on financial relationships or conflicts of interest to an institution, he or she would register on the secure national online database system; create a profile with name, location, and other nonconfidential information; select a permanent ID; and get a confidential password. The system would have procedures for verifying the person's identity. The person's profile associated with the ID would be sufficient to identify the person to public users of the database. (In the case of physicians, the profile might include a field for the National Provider Identifier number.)
- The person would enter, in a standardized format dictated by the database system, at least the minimum standard information on all financial relationships or conflicts of interest that he or she was required to report to an institution. Depending on the person's role in each institution with which he or she had a relationship, more or less information might be required.
- When the person instructed the database to make any information available to any institution, the same information would automatically become available to the public. (Provisions might be made to protect some details of intellectual property, for example, of a drug formula until patent registration.)
- The person-reported information in the database designed by the consensus-development process would ideally be linked to industry-reported information called for in Recommendation 3.4. One objective of the consensus-development process would be to make it convenient to find—in one place, in one format, for any person—any information reported by the person (to an institution) or by industry. Each database could be used to check the completeness of reporting in the other.

We stress the following elements of the model:

- The model would require public reporting only by persons already required to report to institutions and would not add any reporting burden—just "one more press of the button." In fact, the model would probably reduce the overall burden on people by eliminating the need to re-enter information for reporting to multiple institutions.
- The model would make it easier to report correctly by providing explicit standards and instructions.
- The vast majority of practicing physicians do not have to report relationships or conflicts to institutions, so they would not be required to report to the public.
- The information that people would have to report would be limited to financial relationships and conflicts of interests related to drug, medical-device, or biotechnology companies, not other financial or personal information.
- The person-reported information available to the public would add to what would be reported by industry according to Recommendation 3.4 in that it would include information on equity ownership in companies and testing facilities, patent rights, and other types of interests (see list in Table 3-3), not just payments from industry.
- The system of person-reported information would allow people to incorporate more explanatory material about payments received (for example, reasons for payments for consulting) than would probably be reported by industry.
- The centralized nature of the system would make it easier to update reporting requirements for everyone involved if future consensus-development processes deemed it important to include different types of information in standard reports.
- The model would allow persons who might rely on information on financial relationships or conflicts of interest to obtain it when they want it—for example, before enrolling in a continuing medical education program or long after participating in one, or when meeting with family and friends before or after meeting with a surgeon rather than in the brief time with the surgeon.

We believe this model would be a strong and flexible tool for managing conflicts of interest. In key areas of health care, including those in the conflict of interest charge as the committee has defined it for purposes of this report, we are troubled by the possible harms that might arise from conflicts between commercial interests and patient and public interests. This is true in research, in education, and in the development of practice guidelines. But we believe that in each of these areas, totally eliminating all

conflicts—for instance, removing all industry roles in translational research or barring all educational organizations from having any direct or indirect support from industry (even for research or for an endowed chair)—might involve more change than could be justified in light of how research, education, and medical-care systems have evolved. We conclude that greatly expanded requirements for public disclosure would create incentives and monitoring tools that would reduce the risk posed by some of the conflicts that it might not be practical to eliminate.

As documented throughout this report, there are serious limitations in the accuracy, completeness, comparability, and timeliness of conflict of interest information reported to institutions and to the public—for example, as conflicts are shown in National Guideline Clearinghouse documentation of practice guidelines or as conflicts are reported by speakers in continuing medical education programs. These limitations make it difficult for patients, students, clinicians, and others who might be affected by conflicts to make timely assessments of their presence or severity. These limitations also make it difficult for researchers, the press, policy makers, and others to assess the extent of conflicts and the effectiveness of efforts to manage them. We believe that the broader-disclosure model would help to overcome the limitations of currently available information and that the information made available by the model would encourage and facilitate expanded efforts by researchers, the press, public-interest groups, and other information intermediaries to assess and compare conflict of interest policies and practices of all relevant parties.

Even if information on financial relationships or conflicts of interest were rarely used by patients, physicians, or others to make decisions, the fact of public reporting would probably motivate some researchers, physicians, and senior officials to eliminate unproductive conflicts. The model would also create incentives for people to report to institutions completely and accurately to avoid the risk of being identified as having failed to do so.

We recognize the challenges of reaching broad agreement on standard content, formats, and procedures for reporting in an online system—even if the information would be reported only to institutions and not the public. But we believe, on the basis of academic research and experiences in our own organizations, that the cost of maintaining such a system would be minor. Knowing that the information would be public would encourage organizations to participate in planning and designing the system.

We are aware that proposals for public disclosure often elicit concerns about compromising personal privacy. But most people would not have information on financial relationships or conflicts of interest to report and so would have nothing to report publicly. Most mutual-fund shares, stocks, bonds, bank accounts, salaries from institutions, income from medical

practice, and other forms of assets and income would ordinarily not be reported. We assume that even among people who would have relevant financial interests or conflicts of interest to report, the financial interests involved would usually constitute a relatively minor part of their financial affairs and not be a meaningful indicator of individual or family income or wealth; if this assumption is not accurate, public reporting of the information would be all the more important.

There are numerous examples of public reporting of financial information currently in effect that have not been shown to have substantial adverse consequences or to discourage people from participating in the institutions or programs that require reporting—for example, the required public disclosure of salaries of government employees, the public disclosure of individual contributions to political candidates, the public disclosure (on Internal Revenue Service Form 990) of salaries of higher-paid employees of most tax-exempt nonprofit organizations, and, most pertinent, the currently required public accessibility, under state freedom of information laws, of financial relationships or conflicts of interest reported to state universities and health care systems.

We are not persuaded by arguments that the model would create an unfair imbalance in reporting requirements between physicians who work for institutions and physicians who work only in private practice. We note that physicians who have relationships with universities and other institutions already have reporting requirements (to the institutions and subject to public release in the case of public institutions) that other physicians do not have. And we believe that the distinction between institution-affiliated physicians and other physicians is logical: physicians affiliated with institutions are more likely than other physicians to have equity interests, intellectual-property interests, and other interests that may represent conflicts, whereas reporting by every practicing physician would create a large and burdensome system that would not contribute much public information beyond that expected to be included in the industry disclosures under Recommendation 3.4.

We are aware that there might be concerns about misinterpretation of the disclosed information. In a society with freedom of speech and press, any type of information can be misinterpreted or overemphasized. But we believe that the very discipline of free speech, armed with widely available information, would lead generally to better decisions than would result from less complete information.

II. THE RESPONSE OF THE COMMITTEE MAJORITY TO THE PROPOSED MODEL FOR BROADER DISCLOSURE

Wendy Baldwin, Lisa Bellini, Eric G. Campbell, James F. Childress, Peter B. Corr, Todd Dorman, Deborah Grady, Timothy S. Jost, Robert P. Kelch, Bernard Lo, Joel Perlmutter, Neil R. Powe, Dennis F. Thompson, and David A. Williams

As described in Chapter 3 of the report, the full committee supports the development of a public database for company reporting of payments and generally favors making more information on financial relationships and conflicts of interest public. We do not, however, endorse the proposed broader-disclosure model, which calls for institutions that require disclosure from physicians and researchers to require that those individuals also make their disclosures public each time that they report a financial relationship or conflict of interest to those or any other institutions. (That is, the institution would impose the requirement, but the individual would transmit the information.)

We do not endorse the proposed broader-disclosure model for several reasons. First, most members were not convinced of the value that would be added by the suggested expansion of institutional requirements if the other recommendations made in this report were adopted. According to Recommendation 3.4, pharmaceutical, medical-device, and biotechnology companies would be required to report their payments to various individuals and institutions, and that information would be available in a public searchable database. Depending on how many institutions adopted the additional public-disclosure requirements, the proposed expansion might yield some additional information about relationships or interests, such as holdings in publicly traded stock and possibly some expert-witness fees. Such relationships might already be public in specific contexts, for example, in connection with a journal article or educational presentation. In contrast, congressional action on the Medicare Payment Advisory Commission (MedPAC) proposal for the disclosure of physician-ownership interests in health care facilities would provide information about conflicts of interest that are more likely to influence physician decisions about patient care.

A second concern of the committee majority involved intrusions on privacy if physicians and researchers were required to make public the additional information that they disclose to academic medical centers and other institutions. It is likely that many people will not want further exposure to the risks of identify theft, mischaracterization by the mass media, or other kinds of harm, particularly if the database of expanded disclosures is privately managed. The privacy of family members is also at stake because some institutions require the disclosure of the financial relationships of

spouses or domestic partners and children for some purposes. Managing a secure and up-to-date website with personal information requires resources and expertise to protect against errors in disclosure, to offer ways to correct errors, and to clarify disclosures with supplementary information. If the information becomes public without such safeguards, there could be allegations of intentional deception when honest mistakes occur or when a person discloses information to other institutions that have different requirements or formats for disclosure. A system would also need to protect against the malicious entry of erroneous information. We believe the committee did not have the expertise to investigate many matters like these.

A third concern was the additional cost of expanded public disclosure. For example, the proposed unified database would require that the additional disclosures be approved for integration into a federally mandated and overseen database of company-reported payments, or, alternatively, some party would have to create and manage an integrated, secure private database. Either would involve additional costs for creating, maintaining, updating, and correcting the integrated database and maintaining security. In an era of increasing cost pressures on medical institutions and governments, the committee is not convinced that spending for additional, marginal public disclosures can be justified over such alternatives as spending for electronic medical records. In addition, in the committee's experience, estimates of costs for information systems, even seemingly straightforward ones, often fall short of actual costs.

Fourth, we were concerned about setting up a disparity, in particular, between university faculty and private practitioners and between medical institutions that require additional disclosure and ones that do not. Although it is not clear how many institutions would choose to require physicians and researchers to make public their disclosures to all institutions, the institutions that did so would place an extra burden on people who, for the most part, are faculty members whose relationships and conflicts of interest are already overseen by their academic institutions. In contrast, many physicians in private practice have no reporting requirements and no oversight. Thus, the expansion of disclosure is not targeted to higher-risk situations. Furthermore, unless the additional public reporting of institutional disclosure was mandated by the U.S. Congress, there could be perverse consequences for academic or other institutions that required people to make public the information that they disclose both to those institutions and to other institutions. Some physicians and researchers might be attracted by such transparency; but we believe that others would prefer to work at institutions that kept their disclosures confidential, except when disclosure is required for specific purposes, such as publication of a journal article or participation in the development of a clinical-practice guideline.

Finally, we are concerned about other risks and unintended adverse

consequences of requiring additional public disclosure beyond company-reported payments. For example, the requirement would add to the risk that information from different sources might fail to match exactly because of technical errors or differences in reporting requirements, procedures, or periods.[1] Some might seize on the lack of an exact match as evidence of misbehavior—that is, a deliberately incomplete or inaccurate disclosure—on the part of institutions or individuals, who then might have to respond to public accusations; this would distract from their primary responsibilities for research, education, or clinical care. Misinterpretation already may occur with the reporting of payments by companies to physicians; for example, reporters may treat scientific and promotional consulting as equivalent and deserving of the same criticism.

Overall, the majority of committee members thought that making public the information that physicians and researchers report to institutions was not supported by the principle of proportionality and that responses to conflicts of interest should be based on assessment of their severity. The likely burdens on individuals and institutions of an expanded public-disclosure system beyond that proposed in Recommendation 3.4 or already in place in accordance with other public or private policies are disproportionate to any benefits from the marginal amount of additional information that would be provided.

[1]According to Recommendation 3.3, consistency in institutional disclosure requirements and formats would increase and reporting burdens would decrease for people who must make disclosures to multiple institutions.

G

Committee Biographies

Bernard Lo, M.D. (*Chair*) is professor of medicine and director of the Program in Medical Ethics at the University of California, San Francisco (UCSF). At UCSF, he directs the Research Ethics Component of the Clinical and Translational Sciences Institute, which is funded by the National Institutes of Health (NIH), and he codirects the Policy and Ethics Core, Center for AIDS Prevention Studies. He is national program director of the Greenwall Faculty Scholars Program in Bioethics. He is a member of the Institute of Medicine (IOM), serves on the IOM Council, and has served as chair of the Board on Health Sciences Policy and as chair or member of several IOM committees. He cochairs the Scientific and Medical Accountability Standards Working Group of the California Institute for Regenerative Medicine and serves on the Medicare Evidence Development and Coverage Advisory Committee at the Centers for Medicare and Medicaid Services, the Medical Advisory Panel for the Blue Cross Blue Shield Association Technology Evaluation Center, the Ethics Advisory Committee (uncompensated) for Affymetrix (which develops and supplies genetic research products), and two Data and Safety Monitoring Committees at NIH. In the past he served on the National Bioethics Advisory Committee, the Ethics Working Group of the NIH-sponsored HIV Prevention Trials Network, and the Ethics Committee of the American College of Physicians. Dr. Lo is the author of numerous publications, including *Resolving Ethical Dilemmas: A Guide for Clinicians*. He is board certified in internal medicine and currently teaches courses on clinical ethics and the responsible conduct of research.

Wendy Baldwin, Ph.D., is director of the Population Council's Poverty, Gender, and Youth program. Before coming to the council, she served as executive vice president for research (EVPR) at the University of Kentucky,

Lexington. The EVPR is responsible for grant and contract oversight, including technology transfer and evaluation of conflicts of interest. She also spent three decades at the National Institutes of Health (NIH), completing her service as the deputy director for extramural research, a program that represents more than 80 percent of the NIH budget and that applies conflict of interest policies for researchers who receive NIH funds. Dr. Baldwin, who is a social demographer, has served on the National Research Council Committees on Assessing Behavioral and Social Science Research on Aging and Assessing Interactions Among Social, Behavioral, and Genetic Factors in Health.

Lisa Bellini, M.D., is associate dean for graduate medical education and is also vice chair for education in the Department of Medicine, University of Pennsylvania. Her primary responsibilities revolve around directing educational programs for residents and fellows. She is the program director of the Internal Medicine Residency program, which has 150 residents. In her role as vice chair, she is also responsible for overseeing all of the subspecialty fellowship programs. She spends a large portion of her time teaching trainees at all levels. Given the concentration of her teaching experiences on inpatient services, Dr. Bellini is responsible for the organization and maintenance of inpatient medicine services for over 220 beds and 15,000 admissions per year. In 2005, she assumed responsibility for all of the graduate medical education for the health system. As associate dean, she oversees the education and training of over 850 residents across 61 different programs. Her primary research interests involve the design, implementation, and evaluation of new educational initiatives. Current interests involve issues related to quality of life for the house staff, including sleep deprivation, depression, burnout, and empathy. Her clinical interests include general pulmonary medicine, particularly advanced lung disease.

Lisa A. Bero, Ph.D., is a professor in the Department of Clinical Pharmacy, School of Pharmacy and Institute for Health Policy Studies, School of Medicine, University of California, San Francisco (UCSF). She is vice chair in the Department of Clinical Pharmacy and chair of the UCSF Conflict of Interest Committee. She is also a member of the UCSF Academic Senate Vendor Relations Task Force and has served on numerous institutional and international committees related to conflicts of interest. In addition, Dr. Bero is a member of the World Health Organization (WHO) Essential Medicines Committee and has participated in advising on guidelines related to conflict of interest disclosure for the WHO guidelines development process. She is codirector of the San Francisco Branch of the U.S. Cochrane Center; a member of the Steering Group of the Cochrane Collaboration; and editor for the Cochrane Effective Practice and Organization of Care Group, which

is conducting a meta-analysis of the literature on interventions that are used to change the behavior of health care professionals. She was involved in drafting and incorporating international commentary on the Cochrane Collaboration's Commercial Sponsorship Policy and is currently the funding arbiter for the Cochrane Collaboration. Dr. Bero is a consultant to the *British Medical Journal*. She is a pharmacologist with primary interests in how clinical and basic sciences are translated into clinical practice and health care policy. Her program of research includes examination of the influences on the design and conduct of clinical research and publication of research findings. She also conducts research on university-industry relationships and university conflict of interest policies.

Eric G. Campbell, Ph.D., is an associate professor at the Institute for Health Policy and the Department of Medicine at Massachusetts General Hospital and Harvard Medical School. His main research interests lie in understanding the effects of academic-industry relationships on the processes and outcomes of biomedical research, investigating the effects of local health care market competition on the activities and attitudes of medical school faculty, and understanding the impact of data sharing and withholding on academic science. In addition, he is researching the role of organizational culture in promoting patient safety, and he is participating in a national evaluation of the use of health information technology for the Office of the National Coordinator of Health Information Technology. Dr. Campbell has published numerous articles in professional journals and has delivered numerous presentations at local, national, and international conferences on health care policy, medical education, and science policy. He served on the Institute of Medicine Committee on Alternative Funding Strategies for the U.S. Department of Defense's Biomedical Research Program.

James F. Childress, Ph.D., is the John Allen Hollingsworth Professor of Ethics at the University of Virginia, where he teaches in the Department of Religious Studies and directs the Institute for Practical Ethics and Public Life. He has served as chair of the University's Department of Religious Studies and as codirector of the Virginia Health Policy Center. He is the coauthor of the widely used and cited textbook *Principles of Biomedical Ethics*. Dr. Childress was vice chair of the national Task Force on Organ Transplantation and was a member of the presidentially appointed National Bioethics Advisory Commission (1996 to 2001). He has also served on the board of directors of the nonprofit United Network for Organ Sharing (UNOS), the UNOS Ethics Committee, the Recombinant DNA Advisory Committee of the National Institutes of Health (NIH), the Human Gene Therapy Subcommittee of that committee, and several Data and Safety Monitoring Boards for NIH clinical trials. He is a member of ethics advisory panels for

Roche (on tissue banking and clinical research) and Johnson & Johnson (on stem cell research). He chaired the Institute of Medicine (IOM) Committee on Increasing Rates of Organ Donation, cochaired the National Research Council Subcommittee on Use of Third Party Toxicity Research with Human Test Subjects, and served as a member of IOM committees on assessing genetic risks and establishing a national cord blood stem cell bank program. Dr. Childress is a member of the IOM.

Peter B. Corr, Ph.D., is founder and general partner of Celtic Therapeutics L.L.L.P., a private equity firm focused on the development of innovative therapeutics, the development of alliances that advance solutions for diseases of the developing world, and global advocacy for biomedical innovation. Dr. Corr retired from Pfizer Inc. at the end of 2006, where he served as senior vice president for science and technology. Before that, he served as executive vice president of Pfizer Global Research and Development and president of Worldwide Development. Before joining Pfizer in 2000, Dr. Corr was president of pharmaceutical research and development at Warner Lambert/Parke Davis (until the merger with Pfizer), and he previously served as senior vice president of discovery research at Monsanto/Searle. Dr. Corr also spent 18 years as a researcher in molecular biology and pharmacology at Washington University in St. Louis, Missouri, where he was a professor of medicine (cardiology) and a professor of pharmacology and molecular biology. Dr. Corr owns stock and retains stock options in Pfizer Inc. from his employment at the company, and he sits on the Boards of Directors of CBio, an Australian biotechnology company, and Cibus, an agricultural biotechnology firm headquartered in San Diego, California. His research has been published in more than 160 scientific manuscripts. Dr. Corr serves on the Board of Governors of the New York Academy of Sciences, the Board of Regents of Georgetown University, and several other nonprofit and for-profit boards. He is also a member of the Institute of Medicine's Forum on Drug Discovery, Development, and Translation.

Todd Dorman, M.D., is associate dean and director of continuing medical education as well as a professor of anesthesiology and critical care medicine at the Johns Hopkins Medical Center (JHMC). Among other posts, he is the vice chair for critical care services. Dr. Dorman's research interests include informatics applications in the intensive care unit (ICU), such as remote monitoring of critically ill patients; leadership strategies in the ICU; the creation of a culture of safety; and the application of pharmacokinetic models to drug administration in critically ill patients. He has participated in the development and application of conflict of interest policies in a number of areas within and outside JHMC, including continuing medical education, medical center relationships with commercial entities, guidelines develop-

ment, and scientific journal publication. He served as a co-principal investigator on the project on the effectiveness of continuing medical education funded by the Agency for Healthcare Research and Quality. Dr. Dorman is president of the American Society of Anesthesiologists and vice president of the Society for Academic CME.

Deborah Grady, M.D., M.P.H., is a professor of medicine, associate dean for clinical and translational research, and director of the Women's Health Clinical Research Center at the University of California, San Francisco (UCSF). She is a general internist who provides clinical care for adult women and is an expert on the risks and benefits of postmenopausal hormone therapy. Dr. Grady has received funding for independent research from the National Institutes of Health (NIH) and nonprofit and commercial sources and has led several large, long-term clinical studies. In addition to six current NIH-funded activities, she is currently investigator for one study of the treatment for metastatic breast cancer and two studies of treatments for menopause symptoms that are supported by Bionovo through awards to UCSF under university policies that provide for university ownership of the research data, information, and reports resulting from the research and for independence in the publication of research findings. University policies also state that faculty conducting research that is privately sponsored shall not receive honoraria, consulting fees, or other compensation from the sponsor or serve on any board or in other decision-making capacity for the sponsor during the course of the research. She is one of the directors of the UCSF Clinical and Translational Science Institute and coedited *Designing Clinical Research*, a textbook on clinical research methods. Dr. Grady is also a member of the Executive Committee of the San Francisco Coordinating Center, which provides coordination services for multicenter studies in women's health, aging, and related areas. She has participated in the development of practice guidelines and evidence reviews in a number of areas of women's health and served on the Institute of Medicine committee that assessed the need for clinical trials of testosterone replacement therapy.

Timothy S. Jost, J.D., is the Robert L. Willett Family Professor of Law at the Washington and Lee University School of Law. He is a coauthor of the widely used teaching book, *Health Law*, now in its sixth edition, and is the author of *Readings in Comparative Health Law and Bioethics*, *Health Care at Risk: A Critique of the Consumer-Driven Movement, and Disentitlement*, and the editor of *Health Care Coverage Determinations: An International Comparative Study and Regulation of the Healthcare Professions*. He has written numerous articles and book chapters on health care regulation and comparative health law and policy. Professor Jost was a member of the Institute of Medicine (IOM) committee that assessed and recommended

improvements in the U.S. system for protecting human research participants and was a scholar in residence at the IOM in 2005.

Robert P. Kelch, M.D., is executive vice president for medical affairs at the University of Michigan, Ann Arbor, and chief executive officer of the University of Michigan Health System. He oversees the University of Michigan Hospitals and Health Centers and the University of Michigan Medical School, including their policies governing conflicts of interest in research, education, patient care, and other areas. Earlier, Dr. Kelch served as vice president of the University of Iowa Health System and was previously chair of the Department of Pediatrics at the University of Michigan and physician-in-chief of C. S. Mott Children's Hospital. He has been president of the Society for Pediatric Research and chairman of the American Board of Pediatrics. Dr. Kelch has also served on the American Association of Medical Colleges task force on conflicts of interest as well as numerous other association committees. He is a member of the U.S. Department of Veterans Affairs National Research Advisory Council. His research has focused on pediatric endocrinology. Dr. Kelch is a member of the Institute of Medicine.

Robert M. Krughoff, J.D., is founder and president of Consumers' CHECKBOOK/Center for the Study of Services, an independent, nonprofit consumer organization founded in 1974. The organization publishes local versions of *Consumers' CHECKBOOK* magazine in seven major metropolitan areas (Boston, Massachusetts; Chicago, Illinois; Minneapolis/St. Paul, Minnesota; Philadelphia, Pennsylvania; San Francisco/Oakland/San Jose, California; Seattle/Tacoma, Washington; and Washington, D.C.). The magazine evaluates local service firms such as hospitals, auto repair shops, and banks. The center also has developed the *Consumers' Guide to Hospitals*, *Guide to Health Plans for Federal Employees*, and other materials and services for consumers. Before founding the Center for the Study of Services, Mr. Krughoff served in the U.S. Department of Health, Education, and Welfare (now the U.S. Department of Health and Human Services) as director of the Office of Research and Evaluation Planning and as special assistant to the Assistant Secretary for Planning and Evaluation. He currently serves on the board of directors of the Consumer Federation of America (1984 to the present) and has served on the board of directors of Consumers Union, publisher of *Consumer Reports* magazine. He chairs the Technology Assessment Advisory Committee for the ECRI Institute. Mr. Krughoff is a member of the New York Bar and District of Columbia Bar.

George Loewenstein, Ph.D., is the Herbert A. Simon Professor of Economics and Psychology in the Department of Social and Decision Sciences at

Carnegie Mellon University. Previously, he was on the faculty of the University of Chicago's Graduate School of Business. His research focuses on behavioral economics and neuroeconomics. He is a fellow of the American Psychological Association and was a member of the National Research Council Committee on a Research Agenda for the Social Psychology of Aging. Dr. Loewenstein is coeditor of *Conflicts of Interest: Challenges and Solutions in Business, Law, Medicine, and Public Policy* as well as the author of numerous articles, book chapters, and other publications on topics in economics, psychology, and public policy.

Joel Perlmutter, M.D., is Elliot Stein Family Professor of Neurology and Professor of Radiology, Physical Therapy and Occupational Therapy at Washington University in St. Louis, Missouri, where he is head of movement disorders. He is director of the American Parkinson Disease Association Advanced Research Center for Parkinson Disease, the Huntington Disease Center of Excellence, and the NeuroClinical Research Unit and the Brain, Behavior, and Performance Unit at Washington University. Dr. Perlmutter is a member of the American Academy of Neurology, the Parkinson's Study Group, the Huntington's Study Group, and the Dystonia Study Group and is a fellow of the American Neurological Association. One of Dr. Perlmutter's main research interests is brain imaging investigation of the pathophysiology of Parkinson's disease and related movement disorders. He has participated in the development of conflict of interest policies for clinical research, patient care, and education.

Neil R. Powe, M.D., M.P.H., M.B.A., is University Distinguished Service Professor of Medicine and Epidemiology at the Johns Hopkins School of Medicine and Bloomberg School of Public Health and director of the Welch Center for Prevention, Epidemiology, and Clinical Research, a multidisciplinary clinical research and training center at Johns Hopkins. Dr. Powe also directs the Clinical Research Scholars Program and the Predoctoral Clinical Research Training Program. He is a member of the Institute of Medicine. He is also a member of the Agency for Healthcare Research and Quality National Advisory Committee, the Board of Trustees of the Foundation for Anaemia Research (an independent medical research charity), and the Secretary's Advisory Committee on Human Research Protections (U.S. Department of Health and Human Services). Dr. Powe's research bridges medicine and public health and includes prevention and screening, clinical epidemiology, patient outcomes research, quality of care, technology assessment, and cost-effectiveness analysis. He has participated in the development of clinical practice guidelines and studied their implementation.

Dennis F. Thompson, Ph.D., is Alfred North Whitehead Professor of Political Philosophy in the Government Department and a professor of public policy at the Kennedy School, Harvard University. He was founding director of the universitywide Edmond J. Safra Foundation Center for Ethics from 1986 to 2007 and served as associate provost and later as the senior adviser to the president of the university until 2004. His books include *Restoring Responsibility: Ethics in Government, Business and Healthcare*; *Political Ethics and Public Office*; and *Ethics in Congress: From Individual to Institutional Corruption*. He is also the author (jointly with Amy Gutmann) of *Why Deliberative Democracy?* and *Democracy & Disagreement*. Dr. Thompson, a political scientist, has served as a consultant to the Joint Ethics Committee of the South African Parliament, the American Medical Association, the U.S. Senate Select Committee on Ethics, the U.S. Office of Personnel Management, and the U.S. Department of Health and Human Services.

David A. Williams, M.D., is chief of hematology/oncology and director of translational research at Children's Hospital Boston. He is also Leland Fikes Professor of Pediatrics, Harvard Medical School. He was previously director of the Division of Experimental Hematology and associate chair for translational research at Cincinnati Children's Hospital Medical Center. He served as the inaugural director of the Herman B. Wells Center for Pediatric Research at the Indiana University School of Medicine and was an investigator of the Howard Hughes Medical Institute for 16 years. Dr. William's research focuses on the study of blood stem cell biology, blood formation, leukemia, and the treatment of genetic blood disorders using gene therapy. He has received several patents, including, among others, three on methods to increase the efficiency of gene transfer for genetic therapies. Dr. Williams is actively involved in gene therapy trials for congenital immunodeficiencies and pediatric cancer. His policy interests include physician-scientist training and the development of more effective approaches to translational research. He is a member of the Institute of Medicine.

Study Staff

Marilyn J. Field, Ph.D., study director, is a senior program officer at the Institute of Medicine (IOM). Her recent projects at the IOM have examined the safety of pediatric medical devices and clinical research involving children. Among earlier projects, she has directed three studies of the development and use of clinical practice guidelines, two studies of palliative and end-of-life care, and congressionally requested studies of employment-based health insurance and Medicare coverage of preventive services. Past positions include associate director of the Physician Payment Review

Commission, executive director for Health Benefits Management at the Blue Cross and Blue Shield Association, and assistant professor of public administration at the Maxwell School of Citizenship and Public Affairs, Syracuse University. Her doctorate in political science is from the University of Michigan, Ann Arbor.

Franklin Branch is a research associate for the Board on Health Sciences Policy. Before joining the Institute of Medicine, he worked for the Adolescent Health Research Group at Johns Hopkins University and at the American Association of People with Disabilities. Mr. Branch graduated with a B.A. in psychology from the University of Michigan, Ann Arbor.

Robin E. Parsell is a senior program assistant for the Board on Health Sciences Policy. Before joining the Institute of Medicine, she gained 3 years of community-based preparatory research experience with special populations at the Johns Hopkins University Center on Aging and Health and other applied research experience at the Pennsylvania State University. Ms. Parsell graduated with a B.S. in biology (focus in molecular genetics and biochemistry) and a Certificate in Gerontology from the University of Alabama at Birmingham.

Merck Has Some Explaining To Do Over Its MMR Vaccine Claims

09/25/2014 05:29 EDT | **Updated** 11/27/2014 05:59 EST

Merck, the pharmaceutical giant, is facing a slew of controversies over its Measles-Mumps-Rubella (MMR) vaccine following numerous allegations of wrongdoing from different parties in the medical field, including two former Merck scientists-turned-whistleblowers. A third whistleblower, this one a scientist at the Centers for Disease Control, also promises to bring Merck grief following his confession of misconduct involving the same MMR vaccine.

The controversies will find Merck defending itself and its vaccine in at least two federal court cases after a U.S. District judge earlier this month threw out Merck's attempts at dismissal. Merck now faces federal charges of fraud from the whistleblowers, a vaccine competitor and doctors in New Jersey and New York. Merck could also need to defend itself in Congress: The staff of representative Bill Posey (R-Fla) -- a longstanding critic of the CDC interested in an alleged link between vaccines and autism -- is now reviewing some 1,000 documents that the CDC whistleblower turned over to them.

The first court case, United States v. Merck & Co., stems from claims by two former Merck scientists that Merck "fraudulently misled the government and omitted, concealed, and adulterated material information regarding the efficacy of its mumps vaccine in violation of the FCA [False Claims Act]."

According to the whistleblowers' court documents, Merck's misconduct was far-ranging: It "failed to disclose that its mumps vaccine was not as effective as Merck represented, (ii) used improper testing techniques, (iii) manipulated testing methodology, (iv) abandoned undesirable test results, (v) falsified test data, (vi) failed to adequately investigate and report the diminished efficacy of its mumps vaccine, (vii) falsely verified that each manufacturing lot of mumps vaccine would be as effective as identified in the labeling, (viii) falsely certified the accuracy of applications filed with the FDA, (ix) falsely certified compliance with the terms of the CDC purchase contract, (x) engaged in the fraud and concealment describe herein for the purpose of illegally monopolizing the U.S. market for mumps vaccine, (xi) mislabeled, misbranded, and falsely certified its mumps vaccine, and (xii) engaged in the other acts described herein to conceal the diminished efficacy of the vaccine the government was purchasing."

These fraudulent activities, say the whistleblowers, were designed to produce test results that would meet the FDA's requirement that the mumps vaccine was 95 per cent effective. To the whistleblowers' delight, the judge dismissed Merck's objections to the case

proceeding, finding the whistleblowers had plausible grounds on all of the claims lodged against Merck.

If the whistleblowers win, it would represent more than a moral victory (they repeatedly tried to stop Merck while still in its employ). Under the False Claims Act, the whistleblowers would receive a share -- likely 25 per cent to 30 per cent -- of the amount the government recovers. Previous settlements involving extensive fraud by pharmaceutical companies under the False Claims Act have run into the hundreds of millions of dollars, and in some cases such as against GlaxoSmithKline and Pfizer, into the billions.

The second court case, Chatom Primary Care v. Merck & Co. relies on the same whistleblower evidence. This class action suit claims damages because Merck had fraudulently monopolized the mumps market. Doctors and medical practices in the suit would be able to obtain compensation for having been sold an overpriced monopolized product, and a defective one to boot, in that the mumps vaccine wasn't effective (indeed, the suit alleged that Merck expected outbreaks to occur and, as predicted, they did -- mumps epidemics occurred in 2006 in a highly vaccinated population and again in 2009-2010).

"Plaintiffs have argued sufficient facts to sustain a claim for proximate causation, detailing the significant barriers that other companies would face to enter the mumps vaccine market," the court ruled.

The third whistleblower -- a senior CDC scientist named William Thompson -- only indirectly blew the whistle on Merck. He more blew it on himself and colleagues at the CDC who participated in a 2004 study involving the MMR vaccine. Here, the allegations involve a cover-up of data pointing to high rates of autism in African-American boys after they were vaccinated with MMR. In what could be high-profile House hearings before Congressman Posey's Science Committee -- hearings made all the more explosive given the introduction of race into the mix -- Merck could find itself under unprecedented scrutiny. The CDC still stands by its study although Frank DeStefano, the CDC's Director of Immunization Safety and a co-author in the CDC study, also stated that he plans to review his notes with an eye to reanalyzing the data.

Some say all publicity is good. In Merck's case, regardless of the ultimate merits, the publicity will be all bad.

Glaxo Agrees to Pay $3 Billion in Fraud Settlement

By KATIE THOMAS and MICHAEL S. SCHMIDT JULY 2, 2012

In the largest settlement involving a pharmaceutical company, the British drugmaker GlaxoSmithKline agreed to plead guilty to criminal charges and pay $3 billion in fines for promoting its best-selling antidepressants for unapproved uses and failing to report safety data about a top diabetes drug, federal prosecutors announced Monday. The agreement also includes civil penalties for improper marketing of a half-dozen other drugs.

The fine against GlaxoSmithKline over Paxil, Wellbutrin, Avandia and the other drugs makes this year a record for money recovered by the federal government under its so-called whistle-blower law, according to a group that tracks such numbers.

In May, Abbott Laboratories settled for $1.6 billion over its marketing of the antiseizure drug Depakote. And an agreement with Johnson & Johnson that could result in a fine of as much as $2 billion is said to be imminent over its off-label promotion of an antipsychotic drug, Risperdal.

No individuals have been charged in any of the cases. Even so, the Justice Department contends the prosecutions are well worth the effort — reaping more than $15 in recoveries for every $1 it spends, by one estimate.

But critics argue that even large fines are not enough to deter drug companies from unlawful behavior. Only when prosecutors single out individual executives for punishment, they say, will practices begin to change.

"What we're learning is that money doesn't deter corporate malfeasance," said Eliot Spitzer, who, as New York's attorney general, sued GlaxoSmithKline in 2004 over similar accusations involving Paxil. "The only thing that will work in my view is C.E.O.'s and officials being forced to resign and individual culpability being enforced."

The federal whistle-blower law, officially the False Claims Act, dates to 1863 and was originally envisioned as a check on war profiteering after the Civil War.

Whistle-blowers get a share of any money recovered by the federal government. So far, according to Patrick Burns, spokesman for the whistle-blower advocacy group Taxpayers Against Fraud, at least $10 billion has been agreed to in settlements this fiscal year, which ends in September.

The settlement, which requires court approval, stems from claims made by four employees of GlaxoSmithKline, including a former senior marketing development manager for the company and a regional vice president, who tipped off the government about a range of improper practices from the late 1990s to the mid-2000s.

Prosecutors said the company had tried to win over doctors by paying for trips to Jamaica and Bermuda, as well as spa treatments and hunting excursions. In the case of Paxil, prosecutors claim GlaxoSmithKline employed several tactics aimed at promoting the use of the drug in children, including helping to publish a medical journal article that misreported data from a clinical trial.

A warning was later added to the drug that Paxil, like other antidepressants, might increase the risk of suicidal thoughts in teenagers. Prosecutors said the company had marketed Wellbutrin for conditions like weight loss and sexual dysfunction when it was approved only to treat major depressive disorder.

They said that in the case of Avandia, whose use was severely restricted in 2010 after it was linked to heart risks, the company had failed to report data from studies detailing the safety risks to the F.D.A.

“Today’s multibillion-dollar settlement is unprecedented in both size and scope,” said James M. Cole, the deputy attorney general. “It underscores the administration’s firm commitment to protecting the American people and holding accountable those who commit health care fraud.”

The initial terms of the settlement were announced in November, and Glaxo had already set aside cash for the settlement. In a statement Monday, the company said it has since changed many of its policies, including no longer rewarding sales representatives for the number of drug prescriptions sold.

Andrew Witty, the chief executive, sought to portray the illegal actions as part of the company’s past.

“Whilst these originate in a different era for the company, they cannot and will not be ignored,” he said in the statement. “On behalf of GSK, I want to express our regret and reiterate that we have learned from the mistakes that were made.”

The three criminal charges involved Paxil, Wellbutrin and Avandia and included a criminal fine of $1 billion. The remaining $2 billion involves fines in connection with a civil settlement over the sales and marketing practices of the blockbuster asthma drug Advair and several other drugs.

Part of the civil settlement also includes claims that the company overcharged the government for drugs. Glaxo did not admit any wrongdoing in the civil settlement.

Despite the large amount, $3 billion represents only a portion of what Glaxo made on the drugs. Avandia, for example, racked up $10.4 billion in sales, Paxil brought in $11.6 billion, and Wellbutrin sales were $5.9 billion during the years covered by the settlement, according to IMS Health, a data group that consults for drugmakers.

“So a $3 billion settlement for half a dozen drugs over 10 years can be rationalized as the cost of doing business,” Mr. Burns said.

Mr. Burns and others have said that to institute real change, executives must be prosecuted criminally or barred from participating in the Medicare and Medicaid programs, an action known as “exclusion.”

This has occurred in only a handful of cases, and rarely in a case involving a major pharmaceutical company. In 2011, four executives of the medical device company Synthes were sentenced to less than a year in prison for conducting clinical trials that were not authorized by the Food and Drug Administration.

That same year, the former chief executive of K.V. Pharmaceutical was sentenced to 30 days in jail and fined $1 million for selling misbranded morphine tablets. The previous year, the Department of Health and Human Services excluded him from doing business with the federal government.

Those in the pharmaceutical industry have stressed that the activities revealed in the recent settlements occurred many years ago, and practices have changed radically since then. The Glaxo settlement includes an agreement by the company to withdraw bonuses from top executives if they engaged in or supervised illegal behavior, believed to be a first.

“That creates pressure and it creates an element of responsibility,” said Erika Kelton, who represented two of the four whistle-blowers in the Glaxo case. “I think it’s a good step in the right direction.”

Correction: July 6, 2012

An article on Tuesday about a fine levied on the British drug maker GlaxoSmithKline for illegal marketing of some of its drugs misstated the use of Depakote, an Abbott Laboratories drug involved in a similar case. It is an antiseizure drug, not an antipsychotic.

A version of this article appears in print on July 3, 2012, on Page A1 of the New York edition with the headline: Drug Firm Guilty In Criminal Case.
